Polarisation. (1) *Of Light.*—An ordinary narrow beam of sunlight has no sides, and is always divided into two equal beams by a crystal of Iceland spar; but if it has once been reflected from glass or water, it will then be found in general that different results, as regards the intensities of these two beams, are produced by turning the crystal of Iceland spar round the axis of the beam into different successive positions. The beam is no longer the same all round, but has acquired sides. On the vibratory or undulatory theory of Light (q.v.) this shows that the vibrations must be transverse to the direction of propagation (see POLARITY). Suppose a long cord, fixed to a distant wall, to be held in the hand; apply a sharp up-and-down movement; an up-and-down wave will run along the cord to the wall; this illustrates the mode of vibration in a beam of *plane polarised* light. Make the hand move in a circle, in a direction contrary to that of the hands of a clock; a wave will run along in the form of a screw; this screw will have the form, and will advance after the fashion, of a corkscrew; this illustrates the mode of vibration in a *right-handed circularly polarised* beam of light. Make the hand move in a circle clockwise; the wave-screw advances in a left-handed fashion; this illustrates *left-handed circularly polarised* light. Make the hand move in an ellipse; an elliptical disturbance travels, screw-fashion, right- or left-handed as the case may be; this represents *elliptically polarised* light. Communicate a series of disturbances of the greatest irregularity in which no one direction, up or down, right or left, has on the whole any predominance; the irregular succession of transverse disturbances which will travel along the cord will represent the vibration in a beam of *common* or *natural* light. Assume that while communicating these irregular disturbances the hand is hampered but not disabled with reference to any particular direction, say up and down; the vibrations in that direction are on the whole less than those from right to left; and the whole complex of irregular disturbances would, if they wrote their own path, tend to fill up an ellipse with their trace-marking rather than to fill up a circle, as the vibrations in common light would tend to do; this would represent the nature of the vibrations in *partially polarised light.* Now suppose a slot in a board, which will allow the cord to swing from end to end of the slot, but will not allow the cord to swing athwart the slot; all those oscillations or components of oscillation which are parallel to the slot will be able to traverse the slot; but those which are at right angles to these will not be allowed to pass. On endeavouring to transmit through the slot the complex of oscillations which illustrate the vibrations of common or natural light, it will be found that no motion at right angles to the slot is transmitted, and that what does pass through is a complex of irregular oscillations restricted to the plane of the slot. A second slot, at right angles to the first, will cut off the whole of what passes through the first; and the propagation of transverse oscillations along a cord may thus be entirely checked. If, however, the second slot be parallel to the first, all the oscillations transmitted by the first may pass through it also; and if it lie in an intermediate direction, the second slot will allow a proportion to pass, which depends upon the angle between the two slots, being proportional to $\cos\theta$, where θ is that angle. The first slot illustrates the functions of a polariser; the second illustrates those of a second polariser or analyser. A polariser reduces incident common light to a plane polarised condition, and an analyser at right angles to the polariser will quench it altogether.

The phenomena of polarised light were first observed in sunlight reflected from water or glass. Common or natural light so reflected is always, except when it retraces its path by direct reflection, more or less partially 'polarised by reflection.' The polarisation is more or less complete according to the angle of incidence. At one particular angle of incidence the reflected light is as nearly plane polarised as the particular reflecting substance employed can make it. At this angle, the so-called 'angle of complete polarisation,' the reflected and the refracted rays are (or tend to be) at right angles to one another, and $\tan i = \mu$, where i is the angle between the incident ray and the normal, and μ is the index of refraction (see REFRACTION). Metal reflectors have no angle of complete, but only of maximum, polarisation; and even among such substances as glass, which are usually said to have an angle of complete polarisation by reflection, it is only those whose index of refraction = 1·46 which can completely polarise common light by a single reflection. In that case the intensity of the reflected plane polarised beam is to that of the original incident beam of common light as 6·52 to 100, or 6·52 per cent. The intensity of light polarised by one reflection is therefore a good deal less than the 50 per cent. which might be secured by any contrivance which effectually acted in a way analogous to the first slot above mentioned. The intensity of light polarised by reflection is greatly improved by using, instead of a single reflecting plate, a pile of plates. A crystal of tourmaline or of iodo-sulphate of quinine will, on the whole, allow only light polarised in one particular plane to pass through; but then it darkens it and colours it. Advantage is accordingly taken of the property of a doubly-refracting transparent crystal, such as Iceland spar, of dividing an incident beam of common light into two equal beams, which are, when they travel in principal sections of the crystal (see REFRACTION, DOUBLE), polarised in planes at right angles to one another, and each of which possesses (absorption apart) half the intensity of the original beam. As these two beams diverge from one another it is comparatively easy to arrange that one of them shall remain parallel to the axis of the incident beam and of the apparatus, while the other is allowed to wander away laterally: and this is the basis of the construction of the prisms of Nicol, Foucault, Wollaston, Rochon, and others, which receive incident ordinary light and transmit plane polarised light.

Two beams of plane polarised light can *interfere* with one another (see INTERFERENCE) when their vibrations are wholly or partly in the same direction, but not if they be at right angles to one another; and a beam of light polarised in any way can give rise to the phenomena of *Diffraction* (q.v.).

On interposing in the path of a plane polarised beam of light an analyser, so placed as to allow none of that light to be transmitted, and then placing in the course of the plane polarised beam before it reaches the analyser a thin film of a doubly-refracting substance, such as mica, the field of view may become filled with light. The doubly-refracting film generally breaks the incident plane polarised beam into two plane polarised beams, which are, after emergence from the film, parallel to one another and on the whole coincident if of sufficient breadth. These two beams are differently retarded in the mica; and, according to the amount

of this relative retardation and to the position of the principal plane of the interposed film, their resultant, that which reaches the analyser, may be a beam plane polarised in the original plane, plane polarised in another plane, elliptically polarised, or circularly polarised. In all these cases except the first, the analyser lets some light through.—If we substitute for the analyser a doubly-refracting crystal, there will in general be two images seen on looking through; but as this crystal itself introduces relative retardations, the result of which depends on the wave-lengths—i.e. on the colours—the different wave-lengths may give different relative intensities in the two images: some wave-lengths may predominate in the one image, the rest in the other; the two images may thus be coloured; and when coloured they will be complementarily coloured. The phenomena of colour produced by the reaction of polarised light upon various doubly-refracting crystals and films, &c.—all which colour-phenomena are due to varying relative retardations of ordinary and extraordinary rays in doubly-refracting media, and are either uniform all over the resultant wave-front or vary with respect to particular parts of it—are of great variety and extreme beauty. For an account of these we refer to Thomas Preston's *Theory of Light* (Lond. 1890).

A beam of plane polarised light may be recognised by means of a crystal of Iceland spar. Paste a piece of paper with a pinhole in it on one end of the crystal; look through, turning the crystal round; each of the two images waxes and wanes and disappears alternately with the other. In partially polarised ordinary light, and in elliptically polarised light, the two images wax and wane alternately with one another, but do not disappear. In circularly polarised and in ordinary light the two images remain equal to one another, and present no variation of intensity. Circularly or elliptically polarised light is converted by a plate of mica of proper thickness into plane polarised light; natural light, unpolarised or partially unpolarised, is not so affected by the same plate of mica. These criteria enable the character of a given beam of light to be readily recognised.

The name of Rotatory Polarisation is given to the phenomenon observed when a beam of plane polarised light is sent through a slice of quartz cut parallel to the axis. The plane of polarisation is found to have been rotated, and that into a different position for each component colour; so that, with white light incident, a crystal of Iceland spar gives two images complementarily coloured, and varying in colour on rotation of the prism. This property of rotation is shared by many substances even in solution: cane-sugar, grape-sugar, camphor act like quartz, rotating the plane of polarisation to the right (dextro-rotatory); fruit-sugar and starch rotate the plane to the left (laevo-rotatory). Upon this property are based various instruments for the quantitative estimation of saccharine solutions, called saccharimeters. If the light whose plane has been rotated be reflected back through the plane-rotating medium, the rotation is reversed, and the light emerges polarised in the original plane. A somewhat similar phenomenon, though much less pronounced, is observed on passing a beam of light through heavy glass in a strong magnetic field; but here, if the path of the light be reversed by reflection, the rotation of the plane is not reversed but doubled.

As to the direction of vibration in a plane polarised ray, a ray polarised by reflection is said to be polarised in the plane of incidence—i.e. in a plane containing both incident and reflected rays: the question is whether the vibration is in this plane or at right angles to it. Fresnel worked out the consequences of the vibration being at right angles to this plane, and arrived (on the assumption that the density of the ether in two media, at whose bounding surface reflection takes place, is different in the two media, while its elasticity is the same in both) at consequences consistent with experiment. Neumann and MacCullagh, from a contrary hypothesis as to the elasticity and density of the ether, and on the hypothesis that the vibrations are parallel to the plane of polarisation, arrived at optical conclusions which, so far as it is possible to test them by experiment, are equally consistent with observation. Clerk-Maxwell's electric or electro-magnetic theory of light, confirmed by Hertz's researches (see MAGNETISM), requires that there should be an undulatory propagation of electric disturbances at right angles to the plane of polarisation, and of magnetic disturbances parallel to that plane.

Polarisation of light is useful in several ways. A polariser can be made to cut off the glare from the surface of water while we look into its depths; or to cut off a large portion of the light which is reflected from haze and obscures our view of landscape; or it may be used in examining the light of the sky, which is partly polarised, because due to reflection (see SKY). A polariser and analyser are of use in examining the strained condition of glass which, when heated or bent, &c., or too suddenly cooled, will give rise between crossed prisms to phenomena analogous to those produced by a doubly-refracting crystal; and they are also of use in low-power microscopic work for the examination or identification of crystals and of many organic structures. Crossed prisms have also been used to reduce the intensity of a beam of light to any required percentage for photometric purposes.

(2) *Polarisation of Dielectric.*—The condition of the dielectric or medium between two opposite charges of electricity: a condition of stress.

(3) *Polarisation of a Galvanic Cell.*—Production of a reverse 'electromotive force' by the deposition of elements of the electrolyte upon, or their combination with, the plates of the cell.

(4) *Polarisation of Electrodes.*—An entirely similar phenomenon in an electrolytic cell. When the battery is taken off, a reverse current flows from the electrolytic cell; this is the basis of the gas battery and of the modern accumulator (see ELECTRICITY).

Polarity, in physical science, a word of various application; but in all its uses there is present the idea of a directed quantity or Vector (q.v.). A sphere, situated in space, is a perfect type of all-sidedness, presenting the same aspect in every direction. Let this sphere, however, begin to rotate about some diameter, and at once it becomes a polar body; it becomes possessed of polarity (see POLES). Looked at from one end, it appears rotating clockwise; looked at from the other, it appears rotating counter-clockwise. A similar polarity is acquired by a body of any shape when it is set spinning about some axis. Hence we may take rotation as a very perfect illustration of kinematic polarity.

Perhaps the most familiar example in physics of a polar body is the magnet. Its polarity is a force-polarity, the ends or *poles* of one magnet having a selective action upon the ends or poles of another. This particular action is, however, only one of a host of manifestations of what is known as Magnetism (q.v.); and the general tendency in modern theory is to explain all magnetic phenomena as being essentially rotational. Thus, again, from a physical or dynamic point of view, we conceive of rotation as a true type of polarity. The phenomena of statical electricity have also been discussed as analogous to certain phenomena in vortex motion.

In electrolytic polarisation, however, it is difficult to see any rotational analogy. Here the electrodes which bring and carry away again the electric current flowing through the decomposing liquid acquire new properties and functions which have distinct directive relations to the current that produced them. See ELECTRICITY, INDUCTION, MAGNETISM.

In all the cases so far mentioned the polarity or polarisation involved is of such a nature as that originally typified by the sphere's rotation; there are two ends which in some respects have opposite characteristics. In polarisation of Light (q.v.), however, this condition is no longer always fulfilled. For instance, a plane polarised ray of light which is stopped by a Nicol prism passes more or less completely as soon as the prism is rotated round an axis codirectional with the ray. The ray has, in fact, peculiarities as regards its sides—its 'polarity' is strictly speaking lateral, not polar. On the other hand, in a circularly polarised ray we have, according to the ordinary theory, a true kinematic polarity of a rotational kind, so that, looking along the ray, we are able to distinguish right-handed and left-handed circular polarisations. It may be mentioned as a final illustration that the rotation of the plane of polarisation by means of quartz or a saccharine solution is not a real polar phenomenon, the rotation being for any one substance always in the same sense relatively to the travelling ray; but that the rotation of the plane of polarisation in a magnetic field is a true polar phenomenon, changing sign with the direction of the field.

Polar Lights. See AURORA BOREALIS.

Polder, in the Netherlands, is land below the level of the sea or nearest river, which, originally a morass or lake, has been drained and brought under cultivation. An embankment, forming a canal of sufficient height to command a run towards the sea or river, is made, and when carried quite round, as in the case of the Haarlem Lake, it is called the *Ringvaart*. At one or more points on the embankment apparatus for lifting water is placed, and worked by wind or steam power. If the lake deepens towards the centre, several embankments and canals are necessary, the one within the other, formed at different levels as the water-surface becomes lessened, a connection being maintained with the outer canal, which secures a run for the drainage water. In the Schermer polder in North Holland are four canal levels, the land between forming long parallelograms. The water from the inner space is lifted into the first canal; that again, with the drainage of the second section, is thrown into the second, and so on until the outer canal is reached, and a fall obtained. The polders in the Netherlands are very numerous, the most important being the Haarlem Lake (q.v.), possibly to be surpassed by that of the Zuider Zee (q.v.). See also HOLLAND, Vol. V. p. 739.

Pole. See ROD.

Pole, DE LA, a family descended from William de la Pole, a Hull merchant, whose son Michael in 1383 became chancellor under Richard II., in 1385 was made Earl of Suffolk, and in 1389 died an exile in France. His grandson William (1396-1450) was the year before his death raised from Earl to be Duke of Suffolk, having since 1445 been practically prime-minister. His administration was a disastrous one; and he was on his way to a five years' banishment in Flanders, when he was captured by a ship sent after him, and beheaded. John de la Pole, Duke of Suffolk (died 1491), married Elizabeth, sister to Edward IV. and Richard III.; and from this marriage sprang John, Earl of Lincoln (died 1487), Edmund, Earl of Suffolk (executed by Henry VIII., 1513), two churchmen, four daughters, and Richard, on whose death at the battle of Pavia in 1525 the line became extinct.

Pole, REGINALD, 'Cardinal of England,' was the son of Sir Richard Pole, and Margaret, Countess of Salisbury, the daughter of the Duke of Clarence and niece of Edward IV. He was born in Staffordshire, March 1500. He received the rudiments of his education from the Carthusians at West Sheen, and at twelve years of age he was sent to Magdalen College, Oxford. His relationship to the crown made him an important person, and being destined for the church, he was presented at an early age with several benefices. At nineteen he went to Italy with a pension from the king to finish his studies at Padua. He returned to England in 1525. He was then high in Henry's favour, while Queen Catharine was much attached to his mother. Pole's position, when the question of the king's divorce was raised, became a difficult one. He appeared at first disposed to take the king's side. In 1530 we find him in Paris endeavouring to obtain from the university a decision favourable to the divorce, but shortly afterwards he became disgusted with the policy of Cromwell, refused the archbishopric of York which was offered to him on the death of Wolsey, and remonstrated with the king upon the course he was pursuing. Henry, however, made no open quarrel with him; and Pole left England in 1532, and after a short stay at Avignon took up his residence in Italy. Here he formed intimate friendships with a number of men of learning and piety—Sadoleto, Contarini, Morone, Flaminio, Priuli, and others—who were urgent for an internal reformation of the church, and whose views on justification by faith as a rule approximated closely to the doctrine of Luther. Pole still retained his English ecclesiastical revenues, and made no hostile demonstrations against Henry, but in 1535 he entered into a political correspondence with the Emperor Charles V. Pole was now compelled by Henry to declare himself, which he did in a violent letter addressed to the king, afterwards famous in its revised form as the treatise *De Unitate Ecclesiastica*. The king withdrew Pole's pension and preferments. Paul III., on the other hand, made him a cardinal (22d December 1536), and sent him as legate to the Low Countries to confer there with agents of the English malcontents. Henry retaliated by causing a bill of attainder to be passed against him, and by setting a price on his head. His mother, with other relatives, was thrown into the Tower on the ground of treasonable correspondence with the cardinal, and subsequently beheaded. Pole's diplomatic career was not, however, a brilliant one. His several attempts to procure the invasion of England were not successful. From 1539 to 1542 he acted as governor of the 'Patrimony of St Peter,' of which Viterbo was the capital. He took an active part in the discussions on the Interim, and when the Council of Trent was opened in 1545, he was one of the three cardinals who acted as legate-presidents. In the conclave which followed on the death of Paul III. in 1549, Pole was at one moment on the point of being elected pope; after the election of Del Monte, as Julius III., he lived in retirement at a Benedictine monastery at Maguzzano on the lake of Garda, until the death of Edward VI., when he was at once commissioned to proceed to England as legate *à latere*, to assist Queen Mary in the reconciliation of the kingdom to the Church of Rome.

Pole was still only in deacon's orders, and had not abandoned the idea which he had apparently entertained from his youth, of marrying Mary Tudor. The queen for a moment considered the project of obtaining a dispensation for this union with favour, but the influence of Charles V. pre-

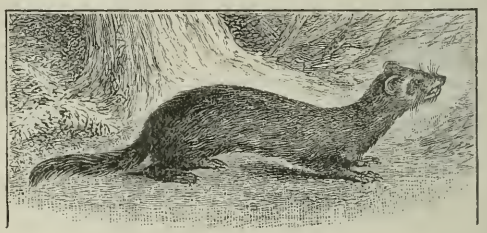
vailed in favour of his son Philip. The emperor's fear of Pole's interference or precipitancy led to the legate being prohibited from entering England for more than a year. Philip was married July 25, 1554. Pole's attainder was removed by parliament, November 22, and two days later he arrived in London. He was provided with ample powers to allow the owners of the confiscated church property to retain their possessions, a condition which was understood to be absolutely necessary to secure the submission of parliament. On the 30th Pole solemnly absolved the Houses of Parliament and country from their schism, and reconciled the Church of England to Rome. As long as Cranmer lived Pole would not accept the archbishopric of Canterbury, although the see was vacant by the former's degradation, but after Cranmer was burnt Pole was ordained priest, 20th March 1556, and on the 22d consecrated archbishop. In the meantime Giovanni Pietro Caraffa, once a friend of Pole and afterwards his bitter enemy, had become (May 1555) Pope Paul IV. The pope was indignant at the concessions made by the authority of his predecessor to the holders of church property; and he revived the accusations of heresy which had been in former days brought against Pole, both on the ground of his leniency towards Lutherans when papal governor at Viterbo, and of his well-known opinions on justification. Paul IV. was, moreover, now at war with Spain, and could not tolerate Pole as his ambassador at the court of Philip and Mary in England. The cardinal's legation was accordingly cancelled, and he was summoned before the Inquisition, into the prisons of which the pope had already thrown Pole's friend, the Cardinal Morone. Mary angrily protested, and the pope somewhat relented. He would not reinstate Pole, but appointed William Peto, a Franciscan friar, as cardinal and legate in his place. The queen gave orders that the papal messenger bearing the hat should be stopped at Calais, and Peto died without receiving it. When peace was made between the pope and Spain, Paul still refused to reinstate Pole as his legate, and he did not withdraw the odious and unjust accusation of heresy. When the queen died, 17th November 1558, Pole, whose health had been long feeble, was lying dangerously ill. The impending failure of all his hopes no doubt hastened his end. He died on the following day, sixteen hours after the queen, in his fifty-eighth year.

It has been a disputed question how far Pole was responsible for Mary's persecution of Protestants. His leniency towards heretics in Italy had even brought him into trouble. Nevertheless it is remarkable that after Philip's departure from England and Gardiner's death (November 1555), when Pole became the queen's supreme adviser and her inseparable companion, the persecution increased in violence. If it was not instigated by Pole, it could not have continued without his sanction and support. In his diocese of Canterbury he issued in the last year of the reign a fresh commission against heretics, and in July he delivered over to the secular arm five persons, who were burnt alive at Canterbury a week before his death.

Besides the above-mentioned *De Unitate*, Pole was the author of *De Concilio* (Rome, 1562), *De summi Pontificis officio* (Louvain, 1560), and *De Justificatione* (Louvain, 1569). His letters, with a life prefixed, were published by Quirini (Brescia, 1744). Beccatelli's life of Pole, originally written in Italian, was published in a Latin translation at London in 1690, and in an English translation by B. Pye in 1766. The first edition of Phillipps' life, which occasioned much controversy, appeared in 1764–67. The fullest recent life of Pole is that by Hook, vol. viii. of his *Archbishops of Canterbury*. Compare Ranke's *Lives of the Popes*, Froude's *History*, and Dixon's *History of the Church of England*, vol. iv.

Pole-axe (originally *pollax*, from *poll*, 'the head,' and *axe*). See BATTLE-AXE.

Polecat, or FITCHET (*Mustela putorius*, or *Putorius fœtidus*), a quadruped of the Weasel family (Mustelidæ), and commonly referred to the same genus with the weasel, stoat or ermine, &c. It is the largest of the six British species of that genus, the length of the head and body being about 1½ foot, the length of the tail more than 5 inches, the form stouter than that of the weasel or of the ermine. Its colour is a deep blackish brown; the head, tail, and feet almost black, the under parts yellowish, the ears edged with white, and a whitish space round the muzzle. The hair is of two kinds —a short woolly fur, which is pale yellow, or somewhat tawny, and long shining hairs of a rich black or brownish-black colour, which are most numerous on the darkest parts. The nose is sharp, the ears short and round, the tail pretty equally covered with longish hair. There is a pouch or follicle under the tail, which exudes a yellowish, creamy substance of a very fetid odour; and this odour is particularly strong when the animal is irritated or alarmed. Hence, apparently, its name *Foumart* ('Foul Marten'), which, with various provincial



Polecat (*Mustela putorius*).

modifications, as *Fulimart*, *Thoumart*, &c., is prevalent in most parts of Britain. The origin of the names Polecat and Fitchet is much more uncertain.

The polecat was much more common in Britain in former times than now, and is almost extirpated from some districts, through the constant war waged against it by gamekeepers and others; and yet it is very prolific, bearing five, six, or even seven young at one birth. It is extremely destructive in the poultry-yard, the abundance present there inviting it to drink blood and eat brains, which seem to be its favourite luxuries. The rabbit is followed by the polecat into its burrow, and its ravages among poultry are partly compensated by its destruction of rats. The taming of the polecat does not seem to have been attempted. The smell prevents it. The skin is imported from the north of Europe under the name of *fitch*, and is used as a kind of fur, similar but inferior to that of the Marten (q.v., and see FURS). To artists the hair of the *fitch* or *fitchet* is well known as that of which their best brushes are made; the hairs used for this purpose being the long hairs already noticed, which grow through the lighter-coloured fur of the animal. The Ferret (q.v.) is supposed by some to be a mere variety of the polecat. A dark-coloured kind of ferret is commonly regarded as a cross between the polecat and the ferret, and is sometimes called the *polecat-ferret*.

Polemoniaceæ, a natural order of plants, mostly herbaceous, allied to Convolvulaceæ, and containing more than 100 known species, natives of temperate countries, and particularly abundant in the north-western parts of America. *Polemonium cæruleum* is Jacob's Ladder (q.v.); Phlox is also of the order.

Polenta, an Italian dish, the chief ingredients of which are maize meal and salt. Sometimes wheat

or chestnut meal is used. It is made into a thick paste, cut into finger-like strips, and baked, generally with an addition of cheese. It is eaten either by itself or with roast liver or steamed meat and sauce. A similar dish, called Mamaliga, is eaten in Transylvania and Lower Hungary.

Poles (Gr. *polos*, a 'turning-point'), in Geography, are the two extremities of the axis round which the earth revolves; they are therefore situated the one on the north, and the other on the south side of the equator, and equidistant from all parts of it, or in 90° N. lat. and 90° S. lat. They are called the north and south poles of the Earth (q.v.).—In Astronomy the poles, which, for distinction's sake, are frequently denominated 'celestial poles,' are those points in the heavens to which the earth's axis is directed, and round which the heavens seem to revolve. The celestial poles are valuable points of reference to astronomers and geographers, so that the determination of their position in the heavens is a matter of the utmost importance. Unfortunately, no stars mark their exact situation (see POLE-STAR)—though there is a minute telescopic star only a few seconds from the north pole, which may be employed instead of it in rough observations—and therefore it is necessary to adopt some means for discovering its precise position. This is effected in the following manner: A bright star (generally the pole-star) is selected, and its position in its upper and its lower *Culminations* (q.v.) is accurately noted; the point midway between these two positions of the star is the pole of the heavens. The observation of the star's two positions must be corrected for refraction, and it is for this reason that the pole-star is selected, since the effect of refraction is much the same in both positions of the star. The term 'poles' has, however, a wider application, as denoting the extremities of a line passing through the centre of a great circle perpendicular to its plane; thus, we have the poles of the horizon (viz. the zenith and nadir), the poles of the ecliptic, the poles of a meridian; and, in the same sense, the terrestrial and celestial poles are spoken of as the poles of the equator and equinoctial respectively.—Pole, in Physics, denotes those points of a body at which its attractive or repulsive energy is concentrated; see POLARITY, and MAGNETISM.

Pole-star, or POLARIS, the nearest conspicuous star to the north pole of the celestial equator. The star which at the present time goes under the name of the 'pole-star' is the star α in the constellation of Ursa Minor. By examining attentively the general movement of the stars throughout a clear winter's night, we observe that they describe circles which are largest at the equator, and become smaller and smaller as we approach a certain point (the north pole of the celestial equator), close to which is the star above mentioned. This 'pole-star' is, however, a little less than $1\frac{1}{2}°$ from the pole, and has a small but sensible motion round it. Owing to the motion of the pole of the celestial equator round that of the ecliptic (see PRECESSION), this star will in course of time (about 2100 A.D.) approach to within 28′ from the north pole, and will then recede from it. At the time of Hipparchus (156 B.C.) it was 12°, and in 1785 2° 2′ from the north pole. Its place can easily be found in the heavens, for a line drawn between the stars α and β (called the two *pointers*, from this peculiarity) of the constellation Ursa Major, or the Great Bear, and produced northwards for about $4\frac{1}{2}$ times its own length, will almost touch the pole-star. Two thousand years ago the star β of Ursa Minor was the pole-star; and about 2300 years before the Christian era the star α in the constellation of the Dragon was not more than 10′ from the north pole; while 12,000 years after the present time the bright star Vega in Lyra will be within 5° of it. See star-map at URSA MAJOR.

The south pole of the celestial equator is not similarly marked by the near neighbourhood of a bright star, the only star deserving the name of the south pole-star being of the sixth or least visible magnitude.

Polianthes. See TUBEROSE.

Police (Gr. *politeia*) is in modern times held to be synonymous with the whole body of men employed as constables, or with the system under which such constables perform their duties in connection with the maintenance of law and order and the prevention and detection of crime. Originally, however, the *politeia* of the Greeks had a much wider signification, and what we now term *police* formed but a part of the regulation of the affairs of a state or country, which was the meaning of the original word. The Greeks, by the adoption of this term, says an old writer on police administration, apparently intended to indicate that the 'execution of those laws which make up public rights, the maintenance of that civil society which is the essence of every city, were two things inseparable from each other.' The strictly executive character of police duties, however, as performed in Great Britain of the 19th century, was not always recognised in ancient times, and whether at Athens, under officers called *archōn* or *nomophylax*, or at Rome, under consuls, prætors, quæstors, censors, or ædiles, the judicial functions of a police-magistrate, or the responsibilities of a public prosecutor, devolved to a greater or less extent upon those officials who were entrusted with police administration. It is difficult to refer to any country in which the separation of executive from judicial or magisterial functions has so strictly been carried out as would appear to be required under our modern interpretation of police duties in England. The French system of police, which is based on the old Roman administration, unites to a very considerable extent executive with judicial functions. The same remark applies to continental police administration generally; and even in the great dependency of British India, which is governed by English law, the district magistrate, who is *ex officio* head of the police within the limits of his jurisdiction, is also a judicial officer with extensive powers. In the capital of England itself, where the distinction between executive and magisterial functions is specially marked, the chief of the police is still, by virtue of his office, a justice of the peace, although the exercise of his powers in that capacity is restricted by certain conditions.

The existing system of police administration in the United Kingdom is of very recent origin; it arose within the 19th century, and in many instances was developed within the reign of Queen Victoria. In the early period of English history there was no such institution as a separate body of police. The responsibility for maintenance of the peace was imposed on each hundred or tithing, and the members of these divisions were held jointly liable for the consequences of any infractions of the laws which took place within their limits. Self-interest made every member of the association a constable; and although the collective responsibility of the tithing or hundred was for executive purposes represented by the headman of each, such transfer of liability was not recognised by the law when any penalty for breach of the peace was incurred. As time went on the place of the headman of the local division was taken by a constable or constables in the various villages or parishes of the country. In the larger towns the members of the various wards at first

maintained order and kept watch within their various limits; gradually separate watchmen, very inadequately paid, were introduced; but the inefficiency with which watch and ward duties were performed, and the impunity with which crimes were committed, were conspicuous, and in no place more so than in the metropolis itself. During the 18th century spasmodic attempts were made to improve the administration in London, both as regards prevention and detection of crime. Horse patrols were introduced; a detective staff was organised; but the whole system was fragmentary and disjointed, and the results attained under it were pre-eminently unsatisfactory. The decrepitude of the old 'Charlies,' as the watchmen were called, and their inability to afford protection to the inhabitants of London, were proverbial; and as to Edinburgh we may read in the pages of the *Heart of Midlothian* Sir Walter Scott's description of 'that black banditti,' the 'City Guard,' who were in his days the 'alternate terror and derision of the petulant brood of the High School,' and objects of scorn to the citizens generally. At last in 1829 Sir Robert Peel constituted the Metropolitan Police, abolishing local police administration in the metropolis outside of the narrow limits of the City of London itself, and placing the control of the new force in the hands of the Secretary of State. Counties and boroughs followed suit in remodelling their police on the administrative principles adopted —save with reference to local control—by Sir Robert Peel in 1829, and since then the present system of police administration throughout the country has been developed on the lines of the original statute, 10 Geo. IV. chap. 44, amplified by 2 and 3 Vict. chap. 47. 'The new guardians of the peace in the metropolis, retaining the comparatively ancient name of constable, were called police-constables, and were in a sense a development of the tithing-man of old; but they resembled him even less than a member for a metropolitan borough resembles the burgesses who appeared before the chief-justices at Westminster with a statement of accounts in the reign of John. Yet the stages of growth are sufficiently well marked—from the responsibility of the tithing to the responsibility of its head, from the functions of the head borough or tithing-man to the functions of the constable, from the election of a constable to the election of a plurality of constables, and finally from a plurality of constables, deputy constables, and watchmen, under parochial or other local authority, to a plurality of constables under the central authority of a Secretary of State' (Pike's *History of Crime in England*, ii. 460).

In 1897 the police force in England and Wales had a total strength of 42,140 officers and men; in Scotland, 4707; Ireland, 12,900. In 1891 the numbers were 37,957, 4194, and 13,977 in the three kingdoms respectively; the total cost being about £5,500,000 a year. The proportion of police engaged in ordinary duties, with reference (*a*) to population and (*b*) to £10,000 of rateable value in the following cities and large towns, is as follows:

Place.	Pop.	Daily Number.	Proportion to Pop.	Number per £10,000.
Metropolitan Police District	5,500,000	12,576	1 to 435	3·60
City of London	50,000	800	1 „ 63	2·10
Liverpool	600,000	1059	1 „ 566	3·20
Glasgow	526,000	1060	1 „ 496	3·16
Birmingham	450 000	550	1 „ 814	3·10
Manchester	380,000	870	1 „ 434	3·60
Leeds	352,000	421	1 „ 834	3·41
Sheffield	322,000	360	1 „ 893	3·35
Edinburgh	255,000	466	1 „ 545	2·55
Newcastle	160,000	255	1 „ 623	2·97
Dundee	160,000	163	1 „ 968	2·50
Dublin	360,000	1195	1 „ 297	10·69

The above figures show that in determining the number of the police the authorities of each city and town have taken into consideration the varying needs and circumstances of each place, rather than to have aimed at subordinating their requirements to a theoretical proportion of police to population.

The police force throughout the country is in all respects a civil body. In the metropolis and in the larger towns it is of course necessary that the constables should be more or less drilled, to enable them when called on to act together in bodies, but the force is in its essence, constitution, and performance of duty, civil and non-military. In exigencies the military forces of the crown can be called out by magistrates to supplement the police in the maintenance of law and order, but, thanks to the law-abiding character of the people, such occasions are of rare occurrence. The only branch of the force of which the constitution is more military than civil is the Royal Irish Constabulary, which will be noticed further on.

The control of the various police forces throughout the country rests with local authorities; the only exception to the rule being the Metropolitan Police, who remain, as they were originally designed to be by Sir Robert Peel, under the authority of Her Majesty's Secretary of State for the Home Department. On the continent of Europe the police forces still remain under the direct control of the state, and to a greater or less extent are frequently used for political purposes, as well as in the conservation of the public peace. In the United States (see below) the principle of local control is general, but in many of the larger cities police appointments are not altogether unconnected with services rendered to local politicians.

Metropolitan Police.—The total strength of the Metropolitan Police in 1898 exceeded 15,000 officers and men, costing more than 1½ million sterling per annum. The Metropolitan Police District (exclusive of the City of London, which has a separate police force), as established by 2 and 3 Vict. chap. 47, extends over a radius of 15 miles from Charing Cross, and embraces a radius of about 700 sq. m. The population of the district may be estimated at not less than 5½ millions; its acreage is about 441,000 acres; and the length of beats covered in the various streets, squares, and roads amounts to 8200 miles. Under 23 and 24 Vict. chap. 135, Metropolitan Police are also employed in Her Majesty's dockyards and in the principal stations of the War Department. The cost of police per inhabitant is about 4s. 8¼d. Since 1868 the cost of the force has been limited to the proceeds of a 9d. rate on the rental assessed in the Metropolitan Police district, of which 4d., till 1889 contributed by the Treasury, is now paid by the county councils, out of the Exchequer Contribution Account, and 5d. by the parishes. In 1890 an annual sum of £150,000 was allotted out of the proceeds of the Local Taxation Act, to defray part of the expenses of police superannuation, so that the amount now available for police purposes in the metropolis may be put down as the total proceeds of the 9d. rate under the original statute, plus £150,000.

That the police of the metropolis is a costly body is apparent. Not only is the population which the force is called on to protect enormous, but it is also exceptionally congested in many localities. The locomotion of such enormous masses of people develops difficulties in dealing with traffic unknown elsewhere. The annual charge for buildings, rents, and taxes is, and must be, higher than in other cities of less magnitude. The necessity for providing a higher organisation to cope not merely with an exceptionally numerous and skilful class of criminals, but to secure the safety of the largest body of citizens in the world while engaged in their lawful occupations, creates sources of expense

peculiar to London; indeed, so many circumstances, non-existent elsewhere, combine to render the administration of this force expensive that in many respects its cost can only be contrasted and not compared with that of even the largest cities and towns of the kingdom.

The system of administration is a development of the principle on which the force was first established by Sir Robert Peel—'unity of design and responsibility of its agents.' The chief officer is the commissioner, who, acting under the immediate authority of the Secretary of State, is responsible for the administration of the system throughout the Metropolitan Police District. The commissioner is vested with the power of a justice of the peace for Middlesex and the home counties, but is debarred from acting in this capacity at general or quarter sessions, or in any manner out of sessions except for the preservation of the peace, or for the prevention of crimes generally. Under the commissioner are three assistant-commissioners, also vested with powers of justices, two of whom deal with details of discipline and ordinary business, the third being specially entrusted with the control of the criminal department.

The whole of the Metropolitan Police District is marked off into twenty-two divisions, each having a force of several hundred men under the charge of a superintendent, aided by a chief-inspector, inspectors, and sergeants. The superintendent is responsible for all the details of police administration within his division. For executive purposes the divisions are brigaded into four police districts, each district comprising several divisions, and being in charge of a superior officer termed chief-constable.

Attached to each of the exterior divisions is a force of mounted men, aggregating in all about 250. The services of this force for ordinary purposes are of more use in outlying places where the beats are long, and where a constable on foot must take a long time to cover his ground, than on the crowded and slippery streets of interior districts; but on occasions of processions, public meetings, and similar demonstrations the mounted force are brought in and perform valuable service. The Thames or River Police are recruited from sailors, and patrol the river in boats and steam-launches. Each principal station is in direct communication by telegraph with the headquarters' office, which, since November 1890, has been situated on the Thames Embankment, and is known as New Scotland Yard; and between every divisional station and its subdivisions the same system of telegraphic communication is maintained. For the detection of crime a special staff of officers is located in each division. Local crime is dealt with by these officers; for the conduct of special cases a separate detective staff is maintained at headquarters, under the control of the superintendent of the Criminal Investigation Department, and the whole detective organisation is specially under the charge of the chief-constable of the Criminal Department and of one of the assistant-commissioners. The supervision of habitual criminals is specially looked after at headquarters by the Convict Supervision Office, under a chief-inspector. The strength of the detective department is above 300 men.

County and Borough Police.—The total number of county and borough police in Great Britain is:

	Counties.	Boroughs.
England and Wales	12,102	10,596
Scotland	1,697	2,675

All such police are under the control of local authorities. By the Local Government Acts of 1888 great changes were made as to the bodies entrusted with such control, and the county councils superseded in many instances the previous agencies for regulating police administration. With reference to counties, the control of the police is vested in a standing committee, consisting of an equal number of justices appointed by the quarter sessions and by the county council. In the case of cities and larger boroughs, which are termed county boroughs, the local councils retain the power which they formerly had, and smaller boroughs are treated as parts of the counties in which they are situated. The control of the Corporation of the City of London over the 'City Police' was in no way affected by the Local Government Acts of 1888. The cost of police, as before, is paid from rates levied in counties and boroughs, supplemented by a contribution from the 'Exchequer Contribution Account' of half the cost of pay and clothing of every force certified to be in an efficient condition. Such contribution was formerly made directly by the Treasury in aid of the local rate under the County and Borough Police Acts. Under the Local Government Acts of 1888, however, such sums, consisting of duties on local taxation, licenses, and the probate-duty grant, are now placed to the credit of the police account of the county fund in counties, and by the county councils disbursed to county police. In boroughs having a separate police force the amounts are paid to and expended by the local councils.

The chief executive officers of county and borough police forces, who are appointed by local authorities, are styled chief-constables; superintendents or head-constables; and for inspection purposes, connected with the grant of a certificate of efficiency, two officers for the whole of England and Wales, and one for Scotland, are appointed by the Secretary of State. The system of administration in cities and large towns is based, as far as circumstances admit, on that which prevails in the Metropolitan Police; in counties where concentration of police is not required the duties are arranged to suit the requirements of each locality. Some of the more important railway companies employ a special staff of railway police.

Police in Ireland.—There are only two police forces in Ireland: the Dublin Metropolitan Police, which has jurisdiction within the limits of the capital, and the Royal Irish Constabulary, which, as an imperial force, performs police duty for the whole of the rest of Ireland.

The Metropolitan Police in Dublin numbers 1214 men, under the command of a commissioner, and its administration is on the lines of the Metropolitan Police.

The Royal Irish Constabulary is the only force in the kingdom which is practically on a military footing, and the members of which are armed, drilled, and disciplined as soldiers. Ordinary civil police duties, both in towns and counties, are performed by this force, but it is unfortunately too often that they are called upon to act as soldiers in repressing organised disturbance. The force is directly under the Irish government. It consists of 12,763 members, officers and men, and is commanded by an inspector-general. Under this officer is a deputy inspector-general, who again is aided by three assistant inspectors-general at headquarters. Each county is supervised by a superior officer called county inspector, and counties again are subdivided into districts, over each of which a district inspector is placed. Below these officers come head-constables, sergeants, and constables, all trained to the use of arms, and disciplined as soldiers.

Police-courts.—These may be termed courts of first instance for hearing criminal cases. In counties such courts are held by justices of the peace, sitting at either petty or special sessions; in boroughs by stipendiary magistrates, or by mem-

bers of the local councils in their magisterial capacity. For the city of London there is one police-court held at the Mansion House, and presided over by the Lord Mayor or one of the aldermen. In the Metropolitan Police District there are fourteen police-courts, the chief of which is held at Bow Street by the chief-magistrate, assisted by two magistrates. To each of the other Metropolitan police-courts two stipendiary magistrates are attached. In Scotland sheriff-courts, both in towns and counties, dispose of a large number of criminal cases remitted to them. The number of criminal offenders convicted in 1890–98 was between 9000 and 8000 a year in England and Wales, between 1900 and 1700 a year in Scotland, and between 1500 and 1000 in Ireland.

France.—In France the police are divided into two great branches—(1) The *Police Judiciaire*, whose business is to discover offenders, gather evidence against them, and hand them over to the proper tribunal (see FRANCE, Vol. IV. p. 776); (2) the *Police Administrative*, whose functions correspond more closely to those of the English police forces in maintaining order. They have, however (as *police générale* and *police municipale*), wider powers and more varied duties, having to superintend public meetings, inspect public food-supplies, administer the laws as to the publication of printed matter, the watching of foreigners, the examination of passports, and regulate the sale of firearms. There is a special department of *police politique*. The armed police, with military organisation, on foot or mounted, known as *gendarmerie* (21,000 men), together with *gardes forestiers* (8000) and *gardes champêtres* (31,000), the *commissaires de police* (1100), and the *agents de police* (14,000), belong to the judicial police. The nearest equivalents to English constables are the *gardiens de la paix*, formerly called *sergents de ville*, of whom Paris has some 6000. The *Service de Sureté* is the detective department.

United States.—In the United States, where each state and each city has its own separate administration, the police system closely resembles that of England. The organisation of a uniformed municipal police is comparatively recent, even in the large cities; in New York it was not substituted for the inefficient night-watch until 1845. The police organisation of that city may be taken as representative of the American system generally. The department of police of the city of New York consists of a 'board of police,' comprising commissioners appointed by the mayor, and the 'police force' and officers appointed by the board. The city (with an area of about 42 square miles before the year 1897, and 318 square miles since) is divided into inspection districts, which are subdivided into precincts. At the head of the force is a superintendent, under whom there are inspectors, a captain over each precinct, sergeants, roundsmen (visiting officers), patrolmen (the body of the force), and doormen at the stations. There are also about a score of police surgeons. The general administration of the force is vested in the board of police, who make appointments, transfers, &c., hear charges against members of the force, and make rules and regulations for the discipline of the department. The orders, however, must not conflict with the constitution of the Union or of the state. The superintendent is the chief executive officer, and is appointed by the board, to whom he makes written quarterly reports; and he receives similar quarterly reports in writing from each of the inspectors. The captains report every morning to the central office. The roundsmen must see that the patrolmen are properly performing their duty, and the sergeants again are responsible for both roundsmen and patrolmen. Besides the general force, there are several 'squads' organised for special duties. These include the 'sanitary police company,' whose members inspect buildings premises, employments, ventilation, sewerage, &c. which are supposed to be dangerous to life or detrimental to health, report nuisances, and seize food unfit for consumption; officers of this company also act as school-board officers, and others, qualified as engineers, inspect steamboats and stationary steam-boilers used for motive power in the city. The detective force is also a separate 'squad;' and others are the mounted squad for duty near Central Park, the mounted patrol for rural precincts, the harbour police, the 'ordinance squad' (for enforcing city ordinances), the Broadway squad (for aiding pedestrians in crossing during the day), special service squads, and others. On the board of police falls the duty of seeing that the streets are kept clean, and a bureau of street cleaning is appointed by the board to supervise this department. Another duty imposed upon the New York police relates to elections: all elections within the city are held under their direction; election officers are appointed by the board, to whom the returns are transmitted. In 1897 the police force of New York was 3500 men, and of Brooklyn 12,000; and since the creation of 'Greater New York' in that year, the number of police has been proportionately increased.

Australasian Colonies.—In New South Wales the number of the police force is 1900; in Victoria, about as many; in South Australia, 500; in Queensland, 900; in Western Australia, 500; in Tasmania, 270; in New Zealand, 530.

See PRISONS, JUSTICE OF THE PEACE; F. W. Maitland, *Justice and Police* (1882); Tiedemann, *Police Power in the United States* (1887); G. W. Hale, *Police and Prison Cyclopædia* (1894).

Polignac, an ancient French family, which claims to derive its name from a castle—the ancient *Apolliniacum*—in the department of Haute-Loire, and which since the 9th century possessed the district of Velay. Among its most famous members was Cardinal Melchior de Polignac (1661–1742), who was employed in diplomatic missions in Poland and at Rome, and received a cardinal's hat after acting as plenipotentiary of Louis XIV. at the peace of Utrecht (1712). From 1725 till 1732 he was French minister at the court of Rome, and he was appointed Archbishop of Auch. Polignac succeeded Bossuet at the French Academy in 1704, and left unfinished the *Anti-Lucretius* (1745), a poem intended for a refutation of Lucretius.

Some other members of the Polignac family are more notorious than noteworthy.—In the reign of Louis XVI. Iolanthe-Martine Gabrielle de Polastron, Duchesse de Polignac (born 1749; died at Vienna, 9th December 1793), and her husband, Jules, Duc de Polignac (died at St Petersburg, 1817), grand-nephew of the cardinal, were among the worst, but unhappily most favoured, advisers of Marie Antoinette. They obtained vast sums of the public money from their royal master and mistress, and were largely responsible for the shameful extravagance of the court. The Polignacs knew how they were hated, and were the first of the *noblesse* to emigrate. From the Empress Catharine of Russia the duke received an estate in the Ukraine, and did not return to France at the Restoration.—His son, AUGUSTE JULES ARMAND MARIE, PRINCE DE POLIGNAC, was born at Versailles, 14th May 1780. On the Restoration he returned to France; became intimate with the Comte d'Artois, afterwards Charles X.; from his devotion to the policy of Rome received from the pope in 1820 the title of Prince; was appointed ambassador at the English court in 1823; and finally, in 1829, became head of the last Bourbon

ministry, in which capacity he promulgated the fatal ordonnances that cost Charles X. his throne. He then attempted to flee, but was captured at Granville on the 15th of August, was tried, and condemned to imprisonment for life in the castle of Ham, but was set at liberty by the amnesty of 1836. He took up his residence in England, but died at St Germain, 2d March 1847. He was a puzzle-headed man; 'a mere idiot' Guizot called him to Bishop Wilberforce.—His son, Prince Armand (1817–90), was a leading monarchist.

Polishing. See FRENCH POLISHING; also DIAMOND, GLASS, GRANITE, &c.

Polishing Slate, a mineral composed chiefly of silica, with a little alumina, lime, oxide of iron, and water; white, yellowish white, or yellow; and of specific gravity about half that of water. It is used for polishing glass, marble, and metals.

Politian. ANGELO POLIZIANO (Latinised *Politianus*) was born at Montepulciano in Tuscany, on the 14th July 1454. His real name was Ambrogini, but, in accordance with a common practice at the Renaissance, he early called himself by the Latinised form of his native town, which Italianised into Poliziano is the name by which he is known in his own country. His father, Benedetto Ambrogini, a jurist of some distinction, was assassinated by certain of his fellow-citizens, and left his widow and five children so scantily provided for that, even after Angelo the eldest had given the most signal proofs of his genius, he was on the point of being taken from his studies and put to a trade. At the age of ten he was sent to Florence, then under Lorenzo de' Medici, the brilliant centre of the Italian Renaissance. Here he had as his teachers the most famous scholars of his time, the Greeks Argyropoulos and Kallistos, and the Italians Landino and Ficino. His progress in the ancient languages, the special studies of the period, was extraordinary even in that age of precocious talents. By his sixteenth year he wrote epigrams in Latin and Greek that excited the wonder of his teachers. At seventeen he began the translation of the *Iliad* into Latin hexameters, a work which it had been the ambition of all the Italian humanists to achieve. The first book had already been translated by another scholar, and Politian at different periods carried on the work to the end of the fifth. By his success with the second book he became known as the 'Homeric youth,' and attracted the attention of the great Lorenzo himself, who now stood his firm friend and patron. Thus secure of a settled position his life was thenceforward devoted to incessant study, and he was soon recognised as the prince of Italian scholars, and the most remarkable literary genius of his time. At the age of thirty he became professor of Greek and Latin in the university of Florence, and the fame of his prelections drew students from every part of Europe, among whom, by reason of their own services to learning, Reuchlin, Grocyn, and Linacre may be specially mentioned. Politian was also entrusted with the education of Lorenzo's sons, Piero and Giovanni (afterwards Leo X.); but their mother Clarice, who had excellent reasons for doubting the great scholar's fitness to be the director of her boys, insisted on his being removed from their immediate superintendence. In such occupation, varied by occasional visits to other towns of Italy, Politian lived at Fiesole in a villa assigned to him by Lorenzo, whose familiar intercourse he daily enjoyed. The death of that prince in 1492 was the most serious trial of his life, and he mourned his death in a Latin elegy, which has been described as unique alike in form and feeling in modern Latin poetry. Two years later he himself died during the temporary supremacy of Savonarola, whose religious zeal was directed against every principle of that pagan revival which it had been the life's work of Lorenzo and Politian to forward. Politian's epitaph on his tomb in San Marco, at Florence, is so entirely in the ironical and sceptical spirit of that movement of which he was so brilliant a representative that it fitly closes any account of himself. It is as follows: 'Politian lies in this grâve, the angel who had one head and, what is new, three tongues.'

Politian has the double distinction of being both a scholar of the first rank and a poet of high merit alike in Latin and in his mother tongue. Of his industry as a scholar his translations of classical authors (Epictetus, Herodian, Hippocrates, Galen, Plato's *Charmides*, to mention a few of the long series) are ample evidence, while his edition of the *Pandects* of Justinian is regarded by modern scholars as excellent even when tried by the latest tests. His original works in Latin fill a thick and closely-printed quarto, half of which is made up of twelve books of letters, and the rest with miscellanies in prose and verse. Among Neo-Latin poets Politian holds perhaps the first place, his peculiar distinction being that, while he is not careful of classical purity, he has charged his verse with his own individual thought and feeling. In Italian literature also he takes a high rank, both in virtue of his own poetic production and as having at a critical period given an impulse to the cultivation of the Italian language. Before him the Italian humanists regarded their native tongue simply as a bastard Latin, which might serve the needs of the people, but was beneath the attention of scholars. The weight of Politian's name and example moved them to think differently, and thenceforward Italian was secure of a place among the other modern literatures. Of his productions in Italian his *Orfeo* deserves special mention as having been the first secular drama in the language. As to his personal character, Politian had in full measure the two great blemishes of the scholars of the Revival of Letters, and notably those of Italy. He was addicted to the lowest forms of vice, and he knew no bounds to his abuse of those who had the ill-fortune to offend him.

See *Opera Ang. Politiani* (Florence, 1499); *Le Stanze, l'Orfeo e le Rime di Messer Ang. Ambrogini, illustrate da Giosuè Carducci* (Florence, 1863). For accounts of Politian, see Roscoe, *Life of Lorenzo de' Medici*; J. A. Symonds, *Renaissance in Italy*, vol. ii.; Von Reumont, *Lorenzo de' Medici* (vol. ii. Eng. trans. 1876).

Political Economy is variously defined. According to the definition most generally accepted in England, it is the science which is concerned with the production, distribution, and exchange of wealth. In Professor Marshall's *Principles of Economics* it is defined as 'a study of man's actions in the ordinary business of life; it inquires how he gets his income, and how he spends it.' The name 'Political Economy' dates only from 1615, having been first used (in this special sense, as distinguished from domestic economy and moral economy and from political theory) by Montchrétien de Vatteville in his *Traité de l'Économie Politique*.

The science of political economy is a branch of the study of man. Man is a creature with many needs, which he seeks to satisfy by applying his labour to the nature by which he is surrounded. These needs are not a fixed quantity, but grow and change with the development of society; and man's devices for their satisfaction receive a corresponding development. In the growth of these needs and of the devices to satisfy them we can trace the economic development of the human race. Political economy may be regarded as the

systematic and comprehensive study of the phenomena connected therewith. There have been economic facts therefore ever since the origin of man; but there was no real science of political economy till it was constructed by Adam Smith and his forerunners in France in the 18th century. Science generally is the systematic study of facts which existed before the study began. Yet, while political economy did not exist as an independent and comprehensive branch of human knowledge before the 18th century, much attention had been given to particular economic facts. Various economic problems had received great and serious attention.

The history of political economy naturally falls into three divisions, *the ancient*, *the mediæval*, and *the modern*. We shall treat them briefly in their order.

(1) *The Ancient Period.*—As in other sciences, the first notable efforts in economic reflection were made by the ancient Greeks. The leading Greek thinkers who handled economic questions were Plato, who in the economic as in other spheres represented the idealism of the ancient world; Aristotle, the exponent of scientific realism; and Xenophon, who expounded the plain common sense of his time and country. Of the problems which they treated with the insight peculiar to their race we may mention the following: the economic aspects of the origin of society; the division of labour; the function of money; economics of slavery, which they considered a natural thing; property and the related question of communism; the dependence of political change and of revolution on economic causes; the population question. On these and other subjects the teaching of the great Greek writers is most valuable; nor is its value lessened by the fact that their discussion of economic facts forms only a part of the science of politics. And, while the conditions of the modern world differ so vastly from the Greek world, the economic views of thinkers like Plato and Aristotle will always have an interest for us, inasmuch as the solid groundwork of human nature continues substantially the same through the changing conditions of history.

Roman economics had no special interest or originality. The main contribution of the Romans in connection with political economy was to give legal form to the prevalent ideas of property.

(2) *The Mediæval Period.*—During this period there was little discussion on economic problems that could now be called scientific. The most interesting feature of the economic views that then existed was the influence exerted on them by Christian teaching. This influence was most profound and greatly affected also the economic thinking of subsequent times. The influence of Christianity was especially manifest in relation to the weak and oppressed classes. It tended to soften and then to abolish slavery and serfdom; it raised the position of women and gave a new refinement to family life; the care of the poor became a first duty of men and of human institutions. The ideas and institutions of property prevalent in the Roman world, which were often harsh, severe, and cruel, were corrected by the spiritual ethics of Christianity. To the struggling and half barbarous feudal world it taught a nobler life and a higher conception of duty in the economic as in other spheres. It inculcated righteousness and charity, forbade usury and luxury, exalted poverty and resignation. In their opposition to the rigorous ideas of property some of the Fathers even advocated communism. The mediæval period was a time of confused struggle, in which Christian ethics were often opposed not only to the rough and warlike egoism of the feudal races, but to the harsh economic ideas that were incorporated in the Roman law.

(3) *The Modern Period.*—The feudal communities were superseded by centralised monarchies; and this great political change was an organic one, being attended by important changes in other spheres. The church lost much of its power. The feudal nobles were transformed into courtiers. The feudal militia gave place to professional armies in the pay and in the immediate service of the monarch. For the maintenance of the army and of the court and other dependents of the centralising ruler it was necessary first of all to have a sufficient revenue. And, as the old revenue in kind was neither convenient nor effective, it was found particularly desirable to have a revenue in money. Accordingly it was one of the greatest and most pressing functions of the statesmanship of that time to foster and to secure an ample revenue in money. The rise of the Colonial System (q.v.) consequent on the discovery of America and of the sea-route to India, the great expansion of commerce thence resulting, the growth of manufactures, the development of the banking system, all these were regarded as elements in the strength of the centralised state, and were made subservient to its policy. Under these circumstances it was natural that special attention should be paid to the balance of trade; that trade should be so regulated by statesmen as to secure for their own country a good balance of the precious metals. Thus it became a special note of economic theory to place an exaggerated value on the precious metals. The Mercantile System (q.v.) was an expression of this exaggeration in the sphere of political economy. Economists differ as to the precise meaning and application of the phrase, and indeed it had no very precise meaning or application. The meaning of the phrase will naturally vary according as we confine the application of it to the exaggeration to which it specifically relates or extend it to the whole system of which the exaggeration was a conspicuous feature. But there can be no doubt that the system grew out of the needs and circumstances of the time. Its chief expounders were Bodin and Montchrétien de Vatteville in France, Antonio Serra in Italy, and Thomas Mun in England. In practical statesmanship it is associated chiefly with the great names of Cromwell and Colbert.

Even during the prevalence of the mercantile system a new way of thinking on economics had arisen in England and France. Its keynote was freedom, and it too was an organic part of the social and political evolution of the time. The expounder of the new system was Adam Smith, but he was only the chief representative and culminating point of a movement which had been growing for more than a century. In England men like Locke, Joshua Child, William Petty, and Dudley North had been struggling more or less successfully towards a similar point of view. In France the school of Physiocrats, headed by Quesnay, had taught many of the new ideas; in particular they had been set forth with perfect lucidity and conciseness by Turgot in his *Réflexions sur la Formation et la Distribution des Richesses* (1766). In fact, Turgot's little book might be regarded as the first scientific exposition of political economy. Adam Smith's achievement was to give the fittest form to ideas which were becoming current among the most progressive minds of his time. If Turgot's work may be regarded as the first brief statement of political economy, Smith's *Wealth of Nations* was the first thorough and comprehensive exposition of the subject by a man who had ample leisure and capacity, a remarkable knowledge of history, and an adequate philosophic training.

The teaching of Adam Smith was by himself well

defined as a system of natural liberty. In view of the ill-judged or antiquated regulations of the past he advocated liberty; and to all that was artificial in such regulation he opposed a natural order, thus following the school of Rousseau in the return to nature from a perverted civilisation. Indeed, both in his assertion of freedom and in the appeal to nature, Smith was only applying to political economy principles that were dominant in other spheres of thought. Smith also followed the example of his predecessors, and showed himself in harmony with the new era, in regarding labour as the source of wealth. With regard to other economic questions relating to capital, rent, interest, &c. Smith has said much which, though it has not always gained the assent of subsequent economists, has at least had the merit of starting important discussion. Smith's pre-eminence as an economist lies in the fact that he summed up and presented in lucid perspective the best economic thought of the times preceding, while his writings were the starting-point of all further development.

The greatness of Smith becomes all the more apparent when we contrast him with his successors, for in none of them do we see the same combination of humanity, moderation, and open-mindedness, fullness of knowledge, width of view, and philosophic culture. Malthus had many of the same qualities, but he fully applied them only to the elucidation of a single aspect of the subject, the population question. In Ricardo the historic factor almost disappears in the abstract; his theory of rent, for which he has been most celebrated, is particularly abstract and artificial, and has been much overrated. The main body of J. S. Mill's economic work was simply a re-statement of the traditionary doctrine, and as an achievement for his time cannot be compared with what Smith did for the 18th century. His later writings as well as the later editions of his *Political Economy* show a perception of the fresh problems which are opening up to the economist, but he never brought his economic system as a whole into harmony with his new views. His economic writings represent a process of transition, in which the old was not fused or transformed by the new.

The political economy of Adam Smith had great influence on the continent of Europe. J. B. Say in France, and Rau and Hermann in Germany, followed Smith more or less faithfully. But Smith's teaching, or what is alleged to have been his teaching, has also met with strong opposition. His doctrines have been variously criticised as being too abstract and individualistic, as inculcating selfishness, as based on doubtful theological assumptions. It is a special objection that his tendency to individualism and cosmopolitanism prevents him from seeing the importance of the nation as an element in economic development. Here we find the most fundamental point of difference between the economics of Germany and of England, plainly arising out of the different circumstances of the two countries. The national element found conspicuous expression in the system of List, who has been followed by the American economist Carey, the gist of this doctrine being that the political economy of each country is and must be adapted to the particular conditions of its national development; in other words, that circumstances render protection necessary to the national life and growth of Germany and the United States.

The school of political economy which has long been most prevalent on the continent of Europe is usually described as *historical*. It holds that economic factors must be studied in the light of the historic conditions of each time and country—conditions legal, political, social, and ethical. The historical school is a protest against abstractness and absoluteness in economic science. No reasonable adherent of the school would deny that there are permanent factors in economics, but all would assert that even the most stable elements are subject to continual variation. That being so, much will depend on whether the economist is disposed to dwell on the stable or the variable elements in economic development. Roscher was the founder of the school. He and Adolf Wagner are its greatest recent representatives. Their works are true to the leading principle of the school; they are studies of economic principles conducted with all the lights which a vast historical learning can supply. Schäffle is more than historical, as he has given ample recognition to the evolution principle in his *Bau und Leben des Sozialen Körpers*.

At present it will be generally admitted by students of political economy that the subject is in an unsettled and unsatisfactory condition. Various explanations of this may be given, but the real and substantial grounds must be found in the following great facts which have emerged since the time of Adam Smith, and which seem to necessitate a reconstruction, or at least a large modification, of the science.

(1) The greatly improved study of history, and the application of the historical method to all departments of inquiry. The charge of neglecting the teachings of history can be urged justly enough against many of Smith's school; against Smith himself it is most unfair. It would be absurd to say that an age which produced Smith and Gibbon was entirely lacking in the historical spirit; both men are amongst the finest examples of it that have appeared. Yet they were only isolated instances of a method which has now become universal among competent inquirers. The comparative study of history, and especially of historical institutions, has practically come into existence since their time, and has thrown entirely new light on the growth and working of economic forces.

(2) The general acceptance of the theory of evolution, especially as taught by Darwin. We can now see that Smith's theory of natural liberty really meant that individual struggle for existence carried on within the limits prescribed by law which we call the competitive system; and that the protective system favoured on the European continent is only a moment in the struggle for existence carried on between vast organised communities like France, Germany, and Russia. In the United States it may be considered as a moment in the struggle for a better national existence against the industrial power of England.

(3) The industrial revolution, whereby hand labour has been superseded by machinery, and individual effort has given place to labour organised in vast industrial and commercial undertakings, such as factories, railway and shipping companies. This revolution was just beginning when Adam Smith wrote his *Wealth of Nations*, which was published in the very year when Watt produced the first effective steam-engine (1776). The change in industrial *technique* and organisation have been vastly greater since Adam Smith's time than they were in the whole period between Aristotle and Smith.

(4) The growth of democracy, which took a fresh start with the American revolution also in the same year that saw the publication of the *Wealth of Nations*, in 1776, to be followed thirteen years later by the great French Revolution of 1789.

(5) The increasing prominence of the social question, of which we need not further speak here.

It cannot be said that the current English economics have given due recognition to any of the above facts. Professor Marshall's important *Prineiples of Economics* (1890), while it is learned, thorough, and progressive in tone, and does considerably show the influence of new movements, is in the main merely a reproduction of the traditionary doctrine. The only prominent thinkers who give due recognition to the evolution principle in economics are Herbert Spencer and Schäffle.

It will be clear that the old abstract economics, of which Ricardo was the signal example, is now being abandoned by all competent economists. Most students of the subject will admit that we can best comprehend the present if we consider it as having grown out of the past; and if we can throw any light on the future, we can do so only by studying both the past and the present. In other words, the great function of the economist is to collect and analyse facts and to inquire into the action of the forces, whatever they may be, that determine the economic well-being of mankind. His aim must be on the one hand to avoid a servile adherence to the historical method, through which the discussion of economic theories is overburdened by a too elaborate apparatus of historical learning, and on the other hand to avoid the assumption that the economic conditions of our own time and country are and must be normal for all other times and countries. While the main body of economic inquiry must be the collection and analysis of facts, the best and most fruitful achievements in political economy accomplished by men like Quesnay, Turgot, Adam Smith, and J. S. Mill have been in forwarding human progress. Thus the ethical or ideal element has not been excluded from political economy at its best. On the contrary, it has informed and inspired the science in its noblest efforts. While political economy must start from an adequate basis of facts supplied by the cognate or subsidiary sciences, geology, geography, statistics, history, it must own allegiance to the supreme science of ethics. Progress in economic science will move in harmony with and promote the social and moral progress of the human race.

Political economy may be regarded as concerned with a vast process which is incessantly going on. This process begins and ends with human beings. The starting-point is found in the needs which stimulate men to those efforts for their satisfaction which are termed labour. But labour can create nothing; it operates by utilising natural objects, or as economists briefly express it, the land, which includes mines and the sea as well as agricultural land. In the history of civilisation a vast system of appliances have, under the name of capital, been developed and accumulated by the labour, ingenuity, and foresight of men for more effective operation on nature; thus we have the three factors of production, land, labour, and capital.

In the system of economics that prevails in the most advanced countries these three factors of production are supplied by as many different classes of individuals, whose relations to each other are determined by free competition. Hence it is that the problems connected with distribution attain to primary importance in political economy. The share of the results of production obtained by the owner of land is rent; the share of the capitalist is called profits, consisting of interest, wages of management, &c.; the share of the labourer is simply termed wages.

One of the most marked features in the recent economic history of the world is the enormous development of the means of communication and transport both by sea and land. In former times the bulk of the produce of labour was locally consumed by the producers themselves. The growing utilisation of steam and electricity has given rise to the great markets of the world, or we should rather say, to a great world-market, in which the exchange of the most varied commodities is carried on. Exchange had long been an important department of economics; it is now a dominant one. Out of exchange arise the problems connected with value. The medium of exchange is money, also involving a wide complex of questions—banking, credit, &c.

The final aim of the whole economic process is the satisfaction of the needs from which it started. This satisfaction is gained in the consumption of the commodities which are produced, distributed, and exchanged; but they are used up not only for enjoyment, but for the production and maintenance of human energies. All human activity, whether it be viewed as the activity of individuals or of the great organised communities, such as states and nations, must rest on an economic basis, and must be more or less limited by the economic resources which it can command. As wealth consists of commodities which are derived from external nature and transformed in the process of production, so in the process of consumption they are returned to nature in a greatly altered form. The subject of consumption has been much neglected by political economists. The utilisation of the materials returned to nature, which are often considered as mere waste, but which could be scientifically applied to the recuperation of the often exhausted powers of nature, has also been greatly neglected in economic *technique*.

The vast process which we have thus briefly sketched is for the most part a private matter. It rests with each individual to determine how he shall relate himself to it. But there is also a large public sphere connected with the state, the municipality, and other local bodies. It has almost universally been admitted that the state must provide for defence, justice, education, the larger means of communication, &c.; and the necessary revenue is mostly drawn from the wealth of the citizens under the name of taxation. An enlarging set of functions, connected with lighting, water-supply, police, and to some extent education, are generally performed by municipalities and other local bodies, the funds for these being styled rates.

Many of the older forms of society were marked by stability or stagnation, and the economic conditions under which they existed underwent little change. Yet economic history has also been a record of development. Labour in particular has gone through a distinct succession of changes, through slavery, serfdom, and the guild system, into the present system of free labour. Discontent has always been the mother of progress, and it is obvious that the economic changes of the present and the future must largely proceed from the discontent of the labouring class, especially from their discontent with the prevailing system of distribution. Hence a group of most important questions connected with trades-unions, co-operation, socialism.

It should also be said that the economic process is an organic one, that each part of it is vitally connected with every other, and that the whole process is intimately related to the entire social, political, artistic, moral, and religious development of mankind. One of the greatest dangers to political economy (as to other sciences) is the excessive specialisation by which certain departments of it are studied in isolation from the other branches of the science, and from the cognate provinces of human knowledge.

Larger works on political economy: Adam Smith, *Wealth of Nations;* J. S. Mill, *Principles of Political Economy;* Cairnes, *Some Leading Principles of Political*

Economy newly expounded; Jevons, *Theory of Political Economy;* Sidgwick, *Principles of Political Economy;* Marshall, *Principles of Economics;* Roscher, *Grundlagen der Nationalökonomie* (Eng. trans.); Adolf Wagner, *Grundlegung;* Schäffle, *Bau und Leben des Sozialen Körpers;* Schönberg's *Handbuch der Nationalökonomie*, which is really an encyclopædia of the subject. Manuals and smaller works: Fawcett, *Manual of Political Economy;* Mrs Fawcett, *Political Economy for Beginners;* Marshall, *Economics of Industry;* F. A. Walker, *Political Economy;* Joseph Garnier, *Traité d'Économie Politique;* Laveleye, *Elements d'Économie Politique* (Eng. trans.). Histories of political economy: Roscher, *Geschichte der Nationalökonomik in Deutschland;* Kautz, *Die geschichtliche Entwickelung der Nationalökonomik;* L. Cossa, *Guide to the Study of Political Economy;* J. K. Ingram, *History of Political Economy; Dictionary of Political Economy*, edited by R. H. Inglis Palgrave. See also the articles BANKING, BOUNTY, CAPITAL, COMMUNISM, CONSUMPTION, CO-OPERATION, CORN LAWS, DIVISION OF LABOUR, EXCHANGE, FREE TRADE, LABOUR, LAND LAWS, MONEY, MONOPOLY, PROTECTION, RENT, SOCIALISM, TAX, TRADE-UNIONS, and WAGES; and the articles on the more important economic thinkers—Smith, Malthus, Ricardo, Mill, Carey, Lassalle, Marx, &c.

Political Offences are usually exempted from treaties of Extradition (q.v.), by which a government agrees to arrest and surrender persons who have broken the law of a foreign state. A political offence may be defined as an offence committed in carrying on civil war or open insurrection. In November 1890 the English judges had to decide whether the Swiss government could demand the extradition of one Castioni, who was proved to have shot a member of the ministry during a revolution excited by the Liberals in the canton of Ticino. There was some evidence that the prisoner was moved by private malice; but the judges held that his act was *primâ facie* political, and gave him the benefit of the exception in the treaty. The Conspiracy Bill of 1858, introduced after Orsini's attempt on the life of Napoleon III., proposed to make conspiracy to murder a felony instead of a misdemeanour. It was intended to secure the French emperor against plotters in England, and caused the fall of Palmerston's government, as being contrary to English traditions. As between a government and its subjects political offences have often been treated with extreme severity, as may be seen on referring to the Roman law relating to *perduellio* and *læsa majestas*. In France and Scotland the law of treason was framed on the model of those laws which had been made to protect the person and government of the Roman emperor and the interests of the Roman state; the old English law of treason was also extremely severe. In modern times the tendency is to treat offences against the state according to the ordinary principles of criminal law. There are, however, two kinds of crime which raise political questions of some interest. (1) Crimes committed in the territory of one state against the government of another. The Foreign Enlistment Acts were passed to enable the British government to deal with persons who levy troops and prepare armaments against a foreign government within British territory. Some writers of authority have censured the American government for permitting Fenians within its jurisdiction to levy war against the British empire. (2) Crimes committed by persons who honestly think they have a grievance against the government of their own country. In such cases the political motive is not, in law, regarded as an excuse; if e.g. a member of parliament incites to a breach of the law, magistrates and prison authorities must deal with him as with any other offender. A humane government will often extend special indulgence to political offences. Whether such indulgence should be granted (whether e.g. an Irish member in prison should be exempted from ordinary prison rules) is a question of discretion, not of legal right. The dynamiters who in 1882–85 attempted the destruction of English public buildings were properly treated as mere criminals, without regard to any alleged political aims.

Politics (Gr. *polis*, 'city' or 'state'), that branch of ethics which has for its subject the proper mode of governing a state, so as to secure its prosperity, peace, and safety, and to attain, as perfectly as possible, the ends of civil society. Among the subjects which political science embraces are the principles on which government is founded, the hands in which the supreme power may be most advantageously placed, the duties and obligation of the governing and governed portions of society, the development and increase of the resources of the state, the protection of the rights and liberties of the citizens, the preservation of their morals, and the defence of the independence of the state against foreign control or conquest. While the philosophy of governing constitutes the *science* of politics, the *art* of politics consists in the application of that science to the individual circumstances of particular states. The ancient Greek writers treated politics with reference to an ideal perfect state, which each propounded according to his own speculative views, pointing out the variation of every existing government from his standard. The 'politics of a country' implies the course of its government, more especially in its relations with foreign powers.

In the articles on the several countries a sketch of the constitution is in most cases given. See also AMBASSADOR, ANARCHISM, ANTHROPOLOGY, ARISTOCRACY, BALANCE OF POWER, CABINET, CONGRESS, DEMOCRACY, ENGLAND (HISTORY OF), FAMILY, FEUDALISM, GOVERNMENT, INTERNATIONAL LAW, NIHILISM, PARLIAMENT, REPUBLIC, REPRESENTATION, SOCIALISM, TRIBE, WHIGS AND TORIES, &c.; and the articles on the expounders of famous political theories—Plato, Aristotle, More, Machiavelli, Bentham, Lassalle, Marx, &c.

Poliziano. See POLITIAN.

Polk. JAMES KNOX, eleventh president of the United States, was born in Mecklenburg county, North Carolina, November 2, 1795. His ancestors, who bore the name of Pollock, emigrated from the north of Ireland; his father was a farmer in moderate circumstances. Polk was educated in the University of North Carolina, and studied law with Felix Grundy of Tennessee, an eminent lawyer and statesman. Admitted to the bar in 1820, he was three years after elected a member of the legislature of Tennessee, and in 1825 returned to congress by the Democratic party. In 1835 he was chosen speaker of the House of Representatives, a position he filled during five sessions with firmness and ability. After serving fourteen years in congress, he was in 1839 elected governor of Tennessee; but he failed to secure re-election in 1841 and 1843. In 1844 he was nominated as a compromise candidate for the presidency, against Henry Clay, and elected by a popular majority of only 38,000, but by 175 electoral votes to 105. His cabinet included James Buchanan as secretary of state and Bancroft, the historian, as secretary of the navy. Polk's firm attitude with regard to the annexation of Texas had mainly secured his election, and he carried out the policy to which he was committed with promptness and vigour. In his first message to congress, in December 1845, he announced that the western bank of the Nueces River, beyond which Texas had not exercised jurisdiction, was already occupied by American troops. On 29th December Texas was admitted to the Union; on the 31st jurisdiction was extended to the disputed territory beyond the Nueces.

These proceedings failing to goad the Mexicans into a declaration of war, the president forced on hostilities by advancing the American army, at the suggestion of General Taylor, to the Rio Grande. Palo Alto and Resaca followed, and the Mexican war was successfully started; the capital was taken in September, and its fall enabled the conquerors to dictate terms of peace, by which the United States acquired California and New Mexico. During Polk's term the Oregon boundary was settled by a compromise (49°) offered by England, though the party cry ('Fifty-four-forty or fight') which helped to elect him was a claim for the entire territory to 54° 40′ N. lat. In 1846 a revenue tariff, in which *ad valorem* were substituted for specific and minimum duties, was adopted—in the senate, however, only by the casting vote of Vice-president Dallas. Polk consistently condemned the anti-slavery agitation; he did not believe in the possibility of a United States all slave or all free, and considered the *modus vivendi* between North and South quite satisfactory. Having pledged himself to a single term of office, he refused a renomination, and retired to his home in Nashville, Tennessee, where he died three months afterwards, June 15, 1849. Polk was a man of good abilities, and of a solid, firm, honest, and religious character. He was devoted to the principles of the Democratic party of Jefferson and Jackson—state rights, a revenue tariff, independent treasury, and strict construction of the constitution.

See Life by J. S. Jenkins (1850), and a History of his administration, by Lucien B. Chase (1850).

Polk, Leonidas, the Antony Bek of the Confederacy, was born at Raleigh, North Carolina, 10th April 1806. He was a cousin of President Polk, and grandson of Colonel Thomas Polk, an officer of the Revolution. Graduating at West Point in 1827, he received a commission in the artillery, but was induced to study for the ministry, and in 1830 received deacon's and in 1831 priest's orders in the Episcopal Church. In 1838 he was consecrated Bishop of Arkansas and Indian Territory, with charge of the dioceses of Alabama, Mississippi, and Louisiana; in 1841 he resigned all these except the bishopric of Louisiana, which he retained—even when at the head of an army corps—until his death. Soon after the outbreak of the civil war he was offered a major-generalship by Jefferson Davis, and, accepting it, proceeded to strongly fortify strategical points on the Mississippi. At Belmont, in November 1861, he was driven from his camp by Grant, but returned and eventually compelled him to retire. At Shiloh and at Corinth he commanded the 1st corps; in October 1862 he was promoted to lieutenant-general, and in November he conducted the retreat from Kentucky. After Chickamauga, where he commanded the right wing, he was relieved of his command; but in December 1863 he was appointed to the department of Alabama, Mississippi, and Eastern Louisiana, and he afterwards joined Johnston in opposing Sherman's march to Atlanta. He was killed while reconnoitring on Pine Mountain, 14th June 1864, by a cannon-shot fired by some Northern officers who wished to give the bishop's party a fright. See the *Life* by W. M. Polk (1894).

Polka, a species of dance, of Bohemian origin, invented in 1830, and introduced into England in 1843, the music to which is in $\frac{2}{4}$ time, and has the rhythmical peculiarity of being accented on the third quaver of the measure.

Pollack (*Gadus pollachius*), a common fish on British coasts, belonging to the cod, haddock, and whiting genus. It is about the size of the coal-fish, is active in habit, and is frequently caught. The lower jaw projects beyond the upper, and there is no barbel. In Scotland and in some parts of Ireland it is called *Lythe*.

Pollaiuolo, Antonio, goldsmith, medallist, metal-caster, and painter, was born at Florence in 1429, and died at Rome in 1498, whither he had been summoned to cast a sepulchral monument for Pope Sixtus IV., and where he also cast a similar one for Pope Innocent VIII. (died 1492), both in St Peter's, and both works of great merit. Antonio's pictures—the best being 'Hercules slaying the Hydra,' 'Hercules destroying Antæus,' and 'St Sebastian'—are distinguished for the life and vigour of their drawing.—His brother Pietro, born at Florence in 1443, and died at Rome in 1496, was generally associated with him in his work, though he devoted most attention to painting. To him are attributed an altarpiece introducing SS. James, Vincent, and Eustace (if indeed it is not mainly by the other brother), an Annunciation, a Coronation of the Virgin, and the Five Virtues.

Pollan (*Coregonus pollan*), a fresh-water fish of the family Salmonidæ, a native of lakes in Ireland. It is particularly abundant in Lough Neagh, where great numbers are often netted, and sold in the neighbouring country. The fish is from 10 to 12 inches in length, and is well flavoured. See Coregonus.

Pollanarrua, a ruined city of Ceylon, 60 miles ENE. of Kandy, with a massive dagoba, a rock-cut temple, masses of sculptured stones, and a wide area of ruined buildings that attest the size and importance of the city, which became the capital of the kingdom about 770, after the Malabar invasion ruined Anuradhapura, the former capital. The city stood on the site of an immense tank, still called Topaweva or Topare. The place was first made known to Europeans in 1820.

Pollarding (*to poll*, to cut off, or shave the head) is the cutting off of the whole crown of a tree, leaving it to send out new branches from the top of the stem. Trees thus treated are called *pollards*. The new branches are never equal in magnitude to the original branches of the tree, although often more numerous, and when pollarding is often repeated the scars and stumps form a thick ring at the top of the stem, from which many small branches spring. Pollards are not beautiful; but pollarding is practised with advantage in districts where fuel is scarce, the branches being cut off in order to be used for fuel, and the operation repeated every third or fourth year. Willows, poplars, alders, elms, oaks, and limes are the trees most frequently pollarded, and in some parts of Europe the white mulberry. The trees of most rapid growth are preferred where fuel is the object; and willows, poplars, and alders are planted along water-courses, and in rows in moist meadows and bogs. Oaks are sometimes pollarded, chiefly for the sake of the bark of their branches, and the whole treatment very much resembles that of copse-wood. See Copse.

Pollen. See Flower (Fertilisation of the), Stamen.

Pollio, Caius Asinius, an orator, poet, historian, and soldier, was born in Rome, 76 B.C. He sided with Cæsar in the civil war fought at Pharsalia, and commanded in Spain against Sextus Pompeius, but was defeated. He sided with the triumvirs against the oligarchic senate, and was appointed by Antony to settle the veterans on the lands assigned them in Transpadane Gaul. It was now that he saved the property of the poet Virgil at Mantua from confiscation. After Antony and Octavian had quarrelled, it was Pollio who effected their temporary reconciliation at Brundusium (40). This year he was consul, when Virgil's fourth

eclogne was addressed to him. The year after he went to Greece as legate of Antony, and defeated the Parthini, a people of Illyria. This was the period of Virgil's eighth eclogne, also addressed to Pollio. Thereafter he withdrew altogether from political life, and survived till 4 A.D. Pollio was the first to establish a public library at Rome, and was the patron of Virgil, Horace, and other poets. His own orations and tragedies and history have perished, and it is most probably no great loss. The severest critics are seldom themselves even decent writers, and he, we are told, detected *Patavinitas* in the limpid style of Livy, and censured Cicero, Sallust, and Cæsar.

Pollock, an illustrious family descended from Mr David Pollock, saddler to George III. in the later part of the 18th century, who kept a shop near Charing Cross. Three of his sons rose to eminence—Sir David Pollock, Chief-justice of Bombay (died 1847); Sir Frederick Pollock; and Field-marshal Sir George Pollock.—The second, FREDERICK, was born 23d September 1783, and in 1802 passed from St Paul's School to Trinity College, Cambridge, where in 1806 he graduated B.A. as senior wrangler and first Smith's prizeman. Next year he was elected a fellow of his college, and called to the bar at the Middle Temple. He travelled the northern circuit; in 1827 became a K.C.; in 1831 was returned as a Tory for Huntingdon; was Attorney-general 1834–35 and 1841–44; and in the last year succeeded Lord Abinger as Chief Baron of the Exchequer. He had been knighted in 1834, and on his retirement in 1866 he received a baronetcy. He died 23d August 1870.—His eldest son, SIR FREDERICK POLLOCK, born 3d April 1815, was educated at Trinity College, Cambridge (1832–36), and in 1838 was called to the bar at the Inner Temple. He was appointed a master of the Court of Exchequer (1846), and Queen's Remembrancer (1874); in 1876 became senior master of the Supreme Court of Judicature; in 1886 resigned his offices; and died 24th December 1888. Besides a good many quarterly and magazine articles, he published a blank verse translation of Dante (1854), and two pleasant volumes of *Personal Remembrances* (1887).—His eldest son, also SIR FREDERICK POLLOCK, third baronet, was born 10th December 1845, and from Eton passed to Trinity, where in 1868 he obtained a fellowship. He was called to the bar at Lincoln's Inn in 1871, and became professor of Jurisprudence at University College, London (1882), Corpus professor of Jurisprudence at Oxford (1883), and professor of Common Law (1884). Besides *Spinoza* (1880), he has published books on *Contract* (1875), *Partnership* (1877), *Torts* (1887; 4th ed. 1895), *Oxford Lectures* (1891); and, with Maitland, *The History of English Law before Edward I.* (2 vols. 1895).—His younger brother, WALTER HERRIES POLLOCK, born 21st February 1850, and likewise educated at Eton and Trinity, was called to the bar at the Inner Temple in 1874, and from 1884 till 1894 was editor of the *Saturday Review*. He is author of *Lectures on French Poets*, *The Picture's Secret*, *Verses of Two Tongues*, *A Nine Men's Morrice*, *Old and New*, &c.—GEORGE FREDERICK POLLOCK (born 1821), third son of the first baronet, became a master of the Supreme Court of Judicature; and the fourth son, SIR CHARLES EDWARD (born 1823), became a baron of Exchequer and judge of the High Court.

SIR GEORGE POLLOCK, field-marshal, was born in Westminster on 4th June 1786, and entered the army of the East India Company as lieutenant of artillery in 1803. Almost immediately after his arrival in India he was engaged in active warfare, in the battle and siege of Deig in Bhartpur (1804), at the siege of Bhartpur (1805), and in other operations in the war against Holkar. Nine years later he saw some service in the Nepal (Goorkha) campaigns of 1814–16, and in the first Burmese war (1824–26) he took an active share, winning his colonelcy. In 1838 he reached the rank of major-general. After the massacre of General Elphinstone and his forces in the passes of Afghanistan (q.v.), the Indian government decided to send a force to the relief of Sir Robert Sale, who was shut up in Jelalabad. The command of the relieving force was given to General Pollock. In April 1842 (5th to 16th) he forced the formidable Khyber Pass, and reached Sir Robert Sale; then, after a few months' delay, he pushed on to Kabul, his object being to restore the prestige of the British arms and to rescue the British prisoners in the hands of Akbar Khan. Both purposes were crowned with success; he defeated the Afghan chief at Tezeen, and destroyed the bazaar in Kabul, and he recovered 135 British prisoners. Then, after being joined by the forces of General Nott, who had marched from Kandahar, he successfully conducted the united armies back to India. He was rewarded with a G.C.B. and a political appointment at Lucknow. He returned to England in 1846, was director of the East India Company for a couple of years (1854–56), and was created a field-marshal in 1870, and a baronet in 1872; in 1871 he was appointed to the honourable office of Constable of the Tower. He died on 6th October 1872, and was buried in Westminster Abbey. See Life by C. R. Low (Lond. 1873).

Pollok, ROBERT, a minor Scottish poet, was born in 1799 at Muirhouse, in the parish of Eaglesham, Renfrewshire. He studied at the university of Glasgow and the Divinity Hall of the Secession Church, and was licensed to preach in 1827. In the same year he published, by the advice of Professor Wilson, *The Course of Time*, in ten books, an attempt at a poetical description of the spiritual life and destiny of man. It was warmly received, but its praises fell on a dying ear, for the poet had meantime been seized with a fatal consumption. He set out, accompanied by his sister, in the hope to reach Italy, but found himself unable to leave England, and died at Shirley Common, near Southampton, 18th September 1827. The *Course of Time*, which is still read in Scotland, is curiously unequal in merit, as we might expect when we remember that its two sources of inspiration were Milton and the *Shorter Catechism*. It contains eloquent passages, but portions of it read like a dull sermon in poor blank verse. Pollok published *Tales of the Covenanters* anonymously before his poem. See the memoir by his brother (1843); Rosaline Masson, *Pollok and Aytoun* ('Famous Scots,' 1899).

Pollokshaws, a manufacturing town of Renfrewshire, on the White Cart, 3 miles SSW. of Glasgow. It derives its name from the 'shaws' or woods of the estate of Pollok, held for more than six centuries by the Maxwells. It was made a burgh of barony in 1814; and its industries, first started in 1742, now comprise power-loom weaving, dyeing, tapestry and chenille manufacturing, bleaching, iron-founding, paper-making, &c. Pop. (1841) 4627; (1881) 9363; (1891) 10,405.

Poll-tax, or CAPITATION TAX, a tax levied by the *poll* or head (*per capita*). In England the imposition of a graduated poll-tax (varying from 4d. to £4, according to rank and wealth) in the time of Richard II. led to Wat Tyler's rebellion in 1381. A similar tax was imposed in 1513; and an unpopular tax (varying from 12d. for a private person to £100 for a duke) was assessed in 1678 and abolished in 1689. In the United States most states impose a poll-tax or capitation tax as a

condition of the suffrage; the sum being generally $1, but in some states only 50 cents, and in others varying from year to year, but not exceeding $3. A considerable number have no such tax; in others the imposition of a poll-tax is expressly prohibited by the constitution. See TAXATION.

Polo, an equestrian game, which may be shortly described as hockey on horseback. It is of oriental origin and of high antiquity; indeed, it has been claimed that it can be traced back to 600 B.C. The accompanying illustration is from a beautifully illuminated Persian MS. of the poems of Háfiz, executed in the year 956 of the Hegira or 1549 of the Christian era, and now in the Bodleian Library, Oxford, by the permission of whose

authorities it has been specially photographed to illustrate this article. It bears the following legend: 'Welcome to the *meidán*, thou chief of horsemen: strike the ball.' Polo was first played by Europeans in 1863 in Calcutta, whither it had been brought by officers who had been stationed in Cachar in Assam, where polo has been played since time immemorial by the hill-tribe of Manipuris. Almost the same game exists in Tibet; whilst native equestrian games more or less closely resembling polo are played in Japan and other parts of the East. Since 1871 many polo clubs have been started in Britain and, since 1876, in America, as well as wherever Britons are found in the East. The principal British club, which makes the rules of the game, is at Hurlingham, near London. The following is a short description of polo: An oblong space of turf is marked out, of which the proper size is 300 yards by 200 yards; at each end in the centre of the line two poles are fixed 22 feet apart, forming the goals through which it is the object of the opposing sides to strike the ball. The players are mounted on ponies, the size of which, according to rule, should not exceed 14 hands; and each player is armed with a polo-stick, consisting of a strong cane about 4 feet long with a cross head about 8 inches long, with which to strike the ball of light wood. The proper number of players is four a side, each of whom has a definite place (numbered one, two, three, and back) in relation to friends and opponents; and in polo, as in most games, combination is perhaps the first condition of success. The ponies have to be carefully trained, and some acquire wonderful cleverness in understanding what is required of them. It is part of the game so to ride alongside an opponent as to prevent him from hitting the ball, but it is not allowed to ride across in front of an opponent. To become a good player requires strength, good horsemanship, a quick eye, and much practice.

See Captain G. F. Younghusband's *Polo in India* (1890), and the chapter on 'Polo' by J. Moray Brown in *Riding* (Badminton Library, 1891).

Polo, MARCO, the greatest of mediæval travellers, was born of a noble family of Dalmatian origin, at Venice, in 1254. His father, Nicolo Polo, and his uncle, Maffeo Polo, both enterprising merchants, had, previous to his birth, set out on a mercantile expedition, visiting Constantinople, the Crimea, and the court of Barka Khan at Sarai. Thence they travelled round the north side of the Caspian Sea to Bokhara, and here they fell in with some envoys returning from Hulagu in Persia to his brother the Great Khan Kublai, and by them were persuaded to accompany them to Cathay. They were well received by Kublai, then either at Cambaluc (Peking) or his summer residence at Shangtu (Coleridge's *Xanadu*), north of the Great Wall. He listened eagerly to their reports concerning the peoples and mode of government in Europe, and commissioned them as envoys to the pope, bearing letters requesting him to send 100 Europeans learned in the sciences and arts, to act as instructors to the Mongols. They reached Venice in 1269, found Rome in the confusion of a long interregnum, and, after the new pope (Gregory X.) was elected, could only get two Dominicans, and even these had hardly commenced the journey when they lost heart and turned back. The Polos made their final start in the November of 1271, taking with them young Marco, and arrived again at the court of Kublai Khan in the spring of 1275, after travelling by Sivas, Mosul, Bagdad, Hormuz, through Khorassan, up the Oxus to the Pamír, by Kashgar, Yarkand, and Khotan, Lob Nor, and across the great desert of Gobi to Tangut, thence to Shangtu. Their second reception was still more honourable than the first, and the khan took special notice of Marco, from the rapidity with which he learned the customs and language of the Mongols. His wisdom and intelligence also recommended him as a fit envoy to the various neighbouring rulers; and during his residence at their several courts Marco observed closely the manners and customs of the country, and delivered on his return a detailed report to the khan. In various missions he visited the western provinces on the borders of Tibet, Yunnan, northern Burma (Mien), Karakorum, Champa or southern Cochin-China, and Southern India. For three years he served as governor of the town of Yang-chow, and with his uncle helped to reduce the city of Saianfu by constructing mangonels for casting stones. The khan long refused to think of the Polos leaving his court, but at length in the beginning of 1292 they succeeded in obtaining permission to join the escort of a Mongol princess, who was travelling to marry Arghun, khan of Persia, grandson of Kublai's brother Hulagu. They sailed from Chwan-chow in Fukien (*Zaitún*), but were detained long on the coasts of Sumatra and Southern India, and only reached Persia after two years had passed. Two of the three envoys and most of their attendants had perished. Arghun Khan himself was dead, but the three Polos and the young princess were safe, and she married the late khan's brother and successor. The Venetians finally reached their native city about the end of 1295, and Ramusio tells the story how like Ulysses they were recognised by none of their kinsfolk, and repulsed from the door. They brought with them much wealth in the portable form of precious stones, the fruits

of their trading. In 1298 Marco fought his own galley in the great battle of Curzola, in which the Venetians under Dandolo were defeated by the Genoese under Doria, and was taken prisoner and immured for a year in a dungeon at Genoa. Here he dictated to another captive, one Rusticiano of Pisa, an account of his journey through the East. After his liberation he returned to Venice, where he died in 1324, and was buried in the church of S. Lorenzo. The traveller bore among his contemporaries the surname or nickname of Marco *Millioni*, most probably from his having frequently used that word in his attempts to describe the wealth and splendour of the khan. The wonders he narrated seem to have excited incredulity—even long after Sir Thomas Browne commends the circumspection of the reader who 'shall carry a wary eye on *Paulus Venetus*, Jovius, Olaus Magnus, Nierembergius, and many others.'

Marco Polo's book consists of two parts: (1) a Prologue, the only part containing personal narrative; (2) a long series of chapters descriptive of notable sights, manners of different states of Asia, especially that of Kublai Khan; and ends with a dull chronicle of the internecine wars of the House of Genghis during the second half of the 13th century. Ser Marco Polo succeeds in almost entirely effacing himself, yet despite his modesty is unconsciously revealed to the eyes of his reader as a man truthful, brave, shrewd, keen-eyed, grave, of few words, fond of sport, with all the due respect of the prosperous man for wealth. He shows throughout a singular lack of humour—Sir Henry Yule cites as almost the solitary instance that in speaking of the khan's paper-money he observes that Kublai might be said to have the true Philosopher's Stone, for he made his money at pleasure out of the bark of trees. Nothing disturbs the even tenor of his narrative—not even when he has to tell of so strange a custom as the couvade among the Gold-teeth on the frontier of Burma. He is no less sparing of scientific observations, and his geographical data are not infrequently the reverse of clear and adequate. He tells us that he acquired several of the languages current in the Mongol empire, and as many as four written characters, but of these Sir Henry Yule thinks Chinese was not one. His work is poorer in information relating to the Chinese proper than anywhere else. Thus, he does not mention the Great Wall, nor yet customs so striking and distinctive as the use of tea, the compressed feet of the ladies, the fishing cormorant, artificial egg-hatching, nor the printing of books. An absurd assertion has been made that block-printing was carried to Europe by our traveller, by him shown to one Panfilo Castaldi, from whom it was learned by John Faust of Mainz; and indeed the printers of Lombardy, misled by patriotic feelings, have stultified themselves by erecting a statue at Feltre to Castaldi, 'the illustrious inventor of movable printing types.' Polo had learned more from men than books, yet it is evident that he had read romances, especially those dealing with the fabulous adventures of Alexander. To these he refers in his notices of the Iron Gate and of Gog and Magog, and of the Dry Tree (*Arbre Sol* or *Arbre Sec*) on the Khorassan frontier. Such stories as these, that of the Land of Darkness, of tailed men, of the great Roc, of trees yielding wine, and the like, go far to account for the grave and matter-of-fact Messer Marco Polo's nickname of *Millioni*.

Ramusio (1485–1557) assumed that the book was first written in Latin. Marsden supposed in the Venetian dialect, Baldelli-Boni showed in his edition (Flor. 1827) that it was French. There exists an old French text, published by the Paris Société de Géographie in 1824, which M. Paulin-Paris describes as the French of a foreigner. This Colonel Yule believes the nearest possible approach to Marco's own oral narrative. About eighty MSS. are in existence, showing considerable variations. These fall naturally into four groups: (1) the old French version already mentioned; (2) a revised French version, the basis of M. Pauthier's edition (1865); (3) a considerably abridged Latin version by Francesco Pipino (about 1490)—not identical with, although similar to, the Latin version published by Grynæus at Basel in the *Novus Orbis* (1532), itself the parent of the 16th-century French editions; (4) a form of the text now alone represented by the Italian recension of Ramusio, published (1559) in vol. ii. of the *Navigationi e Viaggi*. This last text has been subjected to considerable literary modifications, but undoubtedly contains many new circumstances which are substantially supplementary recollections of Marco Polo himself.

The notes of Marsden's excellent English edition (1818) were abridged by T. Wright for Bohn's 'Antiquarian Library' (1854). Another good English edition is that of Hugh Murray (1844); but all its predecessors were set aside by the admirable edition of Colonel Sir Henry Yule (1871; 2d ed. 1875), containing a faithful English translation from an eclectic text, an exhaustive introduction, notes, and other illustrations from the editor's wide learning and intimate knowledge of the East. French or Italian editions worthy of mention are those of the Soc. de Géog. of Paris (1824), Baldelli-Boni (1827), Lazari (1847), Bartoli (1863), and Pauthier (1865). Sir Francis Palgrave's *Merchant and Friar* (1837) is of course a mere work of imagination, in which Roger Bacon and Marco Polo are brought together.

Polonaise, or POLACCA, a Polish national dance of slow movement in $\frac{3}{4}$ time.

Polotsk, a town of Russia, on the Düna (Dwina), by rail 62 miles NW. of Vitebsk and 228 SE. of Riga, is the seat of a bishop of the Greek United Church. Pop. 21,350.

Poltava. See PULTOWA.

Polyandry, the social usage of certain races in stages of civilisation in which the woman normally forms a union with several or many husbands—a condition proved by the researches of M'Lennan and others to be much more important in the development of the social organism than was formerly understood. See FAMILY, MARRIAGE.

Polyanthus (Gr., 'many-flowered'), a kind of Primrose (q.v.), much prized and cultivated by

Polyanthus

florists. It is generally believed to be a variety of the Common Primrose (*Primula vulgaris*), produced by cultivation, in which an umbel of numerous

flowers is supported on a common *scape* (leafless flower-stem), instead of each flower rising on its own stalk from the crown of the root; a modification to which a tendency often appears in the wild plant itself. Thus in its habit it somewhat resembles the cowslip and oxlip, whilst in the size of its flowers it is more like the common primrose; but instead of the pale uniformity of the wild plant it exhibits great variety of delicate and beautiful colours. The subvarieties are innumerable, new ones being continually produced from seed, and of short duration. The seed is sown about midsummer, and flowers may be expected in abundance next year, if the young plants are properly planted out. A rich free soil is most suitable. The polyanthus loves shade and moisture more than its congener, the auricula. It is very hardy, and seldom suffers from the most severe winters. Fine kinds are preserved for a time by dividing the root. The cultivation of the polyanthus is prosecuted with particular assiduity and success in England. For the Polyanthus Narcissus, see NARCISSUS.

Polybius, the Greek historian, was born about 204 B.C. at Megalopolis in Arcadia. From his father Lycortas, one of the leading men of the Achæan League, he received valuable instruction in the science of politics and in the art of war. He was one of the 1000 noble Achæans who, after the conquest of Macedonia in 168, were sent to Rome on the ground that the Achæans had failed to assist the Romans against Perseus. Without any trial the Greeks were detained in an honourable captivity. Polybius was the guest of Æmilius Paulus himself, and became the close friend of his son, Scipio Æmilianus, accompanying him in his military expeditions. Polybius in his turn derived much advantage from the protection and friendship of Scipio, who gave him access to public documents, and aided him in the collection of materials for his great historical work. In 151, after sixteen years in Italy, the surviving Achæan exiles were permitted by the Roman senate to return to Greece; Polybius, however, soon rejoined Scipio, followed him in his African campaign, and was present at the destruction of Carthage in 146. But the outbreak of war between the Achæans and Romans summoned him again to Greece, where he arrived soon after the taking of Corinth. All his influence was now exerted to procure from the conquerors favourable terms for the vanquished; and so grateful were his countrymen for his services in their behalf that they erected statues in his honour at Megalopolis and elsewhere. It must have been about this time that Polybius undertook the writing of his great historical work, the materials of which he had so long been collecting; and in furtherance of his plan he undertook several long journeys—to Asia Minor, Egypt, Upper Italy, southern France, and even Spain—where it has been supposed he witnessed the capture of Numantia by Scipio in 133. He died about 122 B.C.

His history, the design of which was to show how and why it was that all the civilised countries of the world fell under the dominion of Rome, includes the period between 220, where the history of Aratus concluded, and 146 B.C., the year when Corinth fell, and with it the independence of Greece. Much the greater part of the work has perished. Of forty books only the first five are preserved complete; but the plan of the whole work is fully known. Of the two parts into which it was divided the first (books iii.–xxx.; the introductory books i. and ii. being a sketch of the earlier history of Rome) embraced a period of fifty-three years, commencing with the second Punic War and the Social War in Greece, and concluding with the subjugation of the kingdom of Macedonia in 168. The last ten books deal with the years 168–146. The great merits of Polybius are the care with which he collected his materials, his strong love of truth, his breadth of view, and his sound judgment, which was materially assisted by his familiarity with political and military life. He was an excellent authority on the art of war. His tone is didactic, dull, and wearisome; he is too anxious to draw consequences and deduce lessons, and has been called 'the first pragmatical historian.' His method of exposition is careless, somewhat confused, and inartistic; his style, occasionally pithy, but usually bald to a degree, belongs to the period of beginning decadence.

Of the thirty-five books which have not been preserved entire we possess merely fragments or extracts. Fragments were found by Cardinal Mai, and published as late as 1827. Valuable editions have been published by Schweighäuser (1789-95; new ed. Oxford, 1831), Bekker (1844), Dindorf (1862–68; new ed. 1882), Hultsch (1868–72; 2d ed. 1888). The portion on the history of the Achæan league has been edited by W. W. Capes, and selections (based on Hultsch) by Strachan-Davidson (1888); there is a readable English translation by E. S. Shuckburgh (1889). See Mahaffy, *The Greek World under Roman Sway* (1890); German works on Polybius by La Roche (1857) and Pichler (1860); and R. von Scala, *Die Studien des Polybius* (1891 *et seq.*).

Polycarp, one of the 'Apostolic Fathers,' was bishop at Smyrna in proconsular Asia during the earlier half of the 2d century. His is an important name, for he bridges the little known and much controverted period lying between the age of his master the Apostle John and that of his own disciple Irenæus, and his testimony is only the larger, clearer, and more valuable because of his rigid conservatism and lack of intellectual individuality. The 'Life' by 'Pionius' is utterly untrustworthy. All that is really known of Polycarp's origin is gathered from his dying declaration, which shows that he was born about 69 A.D., and probably of Christian parents. By the migration of apostles and others from doomed Jerusalem, Ephesus and the neighbouring districts became the new home of the faith, and there Polycarp was 'taught by Apostles,' John above all, and 'lived in familiar intercourse with many that had seen Christ' (Irenæus, *Heresies*, iii. 3, 4). The further statement that he was appointed bishop in Smyrna 'by Apostles' ('by John'—Tertullian) is probably coloured by the later conception of the episcopate, but he certainly appears to have been head of the church from early manhood.

Among contemporaries he was intimate with Papias. More interesting is his brief intercourse with Ignatius, who, on his way from Antioch to martyrdom at Rome, made a short stay at Smyrna, where Polycarp and the church ministered to him. The tone of his *Epistle to Polycarp*, written shortly after from Troas, is that of a letter to one less experienced, if not younger, and less energetic than the writer, but high respect is paid to Polycarp's stedfastness, piety, and position. In consequence of a request which Ignatius was making to the churches to send messages to Antioch, the Philippians wrote to Polycarp asking that their letter to Antioch might be forwarded by the Smyrnæan messenger, at the same time inviting exhortation, and further asking for any of the epistles of Ignatius that he might have. Hence Polycarp's *Epistle to the Philippians*, in which he accedes to their various requests, and solicits further news of Ignatius. His influence on a younger generation, and his importance as a faithful preserver of the apostolic tradition, are vividly delineated by his greatest disciple Irenæus in his *Epistle to Florinus*, quoted in Eusebius, *Hist. Eccl.* v. 20: 'I can tell the very place where the blessed Polycarp used to sit and discourse. . . . Whatso-

ever things he had heard from them (John and others) about the Lord . . . Polycarp, as having received them from eye-witnesses of the life of the Word, would relate altogether in accordance with the Scriptures.' These valuable reminiscences relate to a period somewhere between 135 and 150 A.D.

At the very close of his life Polycarp visited Rome, where he conferred with the bishop Anicetus, chiefly on the vexed question of the time for commemorating the Passion. On this point neither yielded to the other, yet their relations remained so cordial that Anicetus allowed Polycarp to take his place in celebrating the eucharist (see Irenæus quoted in Eusebius, *Hist. Eccl.* v. 24). After turning many Valentinians and Marcionites from their heresies by his preaching, the aged bishop returned to Smyrna, only to win the martyr's crown in a persecution which broke out during a great festival. Unsatiated with meaner victims, the mob called for Polycarp, 'the father of the Christians.' With truest dignity and modesty does Polycarp play the man. Betrayed by his servant-boy, but offered his life by the proconsul if he will revile Christ, he answers: 'Fourscore and six years have I been His servant, and He hath done me no wrong. How then can I blaspheme my King, who hath saved me?' As the games were over, death by fire was substituted for death by wild beasts, and Jews vied with heathens in providing fuel. But the fire arched itself about the martyr, and he had to be despatched with a dagger. The graphic *Letter of the Smyrnæans* tells the story of the martyrdom to the Philomelian church. A chronological appendix to this letter has been elucidated by Waddington's skilful dating of the 'proconsul,' and his conclusions have been confirmed by the discovery of inscriptions relating to the 'high-priest,' also mentioned therein, so that the martyrdom may, with strong probability, be dated 23d February 155 A.D.

The only writing of Polycarp extant is the *Epistle to the Philippians*, incomplete in the original Greek, but complete in a Latin translation. Its genuineness has been assailed, but unsuccessfully. Somewhat commonplace in itself, it is of great value for questions of the canon, the origin of the church, and the Ignatian Epistles. More New Testament phrases are here inwoven than are found in any other work of the time. Their wider range, and especially the prominence given to Paul and his epistles by this disciple of John, tell heavily against Tübingen theories of the origin of the church and the canon. The letter bears so closely on the Ignatian Epistles that, while apart from it the *external* evidence for their genuineness is weak, with it that evidence is very strong. The grounds, however, for assigning the epistles of Ignatius and Polycarp to the reign of Trajan are not beyond question, while among other things a certain reference to heresy in Polycarp's epistle would better accord with a time about 130 A.D., or even later.

For one of the best editions of the *Epistle* (first edited by Halloix in 1633 and frequently since), see *Patrum Apostol. Opera* (ed. Gebhardt, &c., vol. ii. 1876); for the date of the martyrdom, Waddington's *Fastes des Provinces Asiatiques* (Paris, 1872), and the Oxford *Studia Biblica* (1885 and 1890). But the best and most exhaustive work on all the parts of the subject is Lightfoot's *Apostolic Fathers*, part ii. (2d ed. 1889). An ingenious, scholarly, and able attempt is made by the Rev. J. M. Cotterill in the Cambridge *Journal of Philology* (1891) to attribute the extant epistle to Antiochus, a monk of St Saba, who flourished under Heraclius, and from whose pen is still extant, 'if,' in Gibbon's phrase, 'what no one reads may be said to be extant,' a dull and feeble work entitled Παν δέκτης τῆς ἁγίας γραφῆς, divided into 130 homilies.

Polycotyle'donous Plants are those whose embryos have more than two seed-leaves (cotyledons). Examples are found occasionally, or as monstrosities, among Dicotyledons. In the Pine (Pinus) group of the Coniferæ (q.v.), however, the polycotyledonous condition is the normal one, and the cotyledons occur in whorls of from three to ten. Multiplication of cotyledons occurs in a few other groups of the Coniferæ. Sometimes the numerous cotyledons unite in pairs, and this leads to the suggestion that they originally sprang from two; but many botanists believe that the cotyledons arise as separate leaves.

Polycrates, 'tyrant' of Samos from about 536 B.C. to 522. He conquered several islands of the Archipelago, and even some towns on the Asiatic mainland, waged war successfully against the inhabitants of Miletus, and defeated their allies, the Lesbians, in a great sea-fight. His intimate alliance with Amasis, king of Egypt, proves the importance in which this daring island-prince was held even by great monarchs. According to Herodotus, Amasis dreaded the misfortunes that the envious gods must be preparing for so lucky a mortal, and wrote a letter to Polycrates, earnestly advising him to throw away the possession that he deemed most valuable, and thereby avert the stroke of the spleenful gods. Polycrates, in compliance with this friendly advice, cast a signet-ring of marvellously beautiful workmanship into the sea, but next day a fisherman presented the tyrant with an unusually big fish that he had caught, and in its belly was found the identical ring. It was quite clear to Amasis now that Polycrates was a doomed man, and he immediately broke off the alliance. When Cambyses invaded Egypt (525) Polycrates sent him a contingent of forty ships, in which he placed all the Samians disaffected towards his tyranny, hoping they might never come back; but mutinying they returned to Samos, and made war against the tyrant, but without success. Hereupon they went to Sparta, and succeeded in securing the help of both Spartans and Corinthians. A triple force of Samians, Spartans, and Corinthians embarked for Samos, and besieged Samos in vain, and Polycrates became more powerful than ever; but Nemesis overtook her victim after all. Orœtes, the Persian satrap of Sardis, had conceived a deadly hatred against Polycrates, and, having enticed the latter to visit him at Magnesia by appealing to his cupidity, he seized and crucified him.

Polydipsia. See DIABETES.

Polygalaceæ. See MILKWORTS.

Polygamous, a term applied to plants which bear both unisexual and hermaphrodite flowers, either on the same or on different individual plants. For example, the maple produces male, female, and hermaphrodite flowers on the same tree: while some ash-trees sometimes bear male only, others female, and others hermaphrodite flowers.

Polygamy (Gr. *polys*, 'many,' *gamein*, 'to marry') includes etymologically the social arrangement by which one wife has many husbands, now usually termed Polyandry (q.v.), as well as that in which a man has or may have several or many wives. To the latter the term polygamy is, however, practically restricted. Formerly polygamy was thought to be probably the original type of the development which has culminated in the marriage relations of civilised peoples; that this is not so is shown somewhat fully in the articles FAMILY and MARRIAGE.

Polygamy certainly obtained at one time over a very large area of the world's surface; in general it may be said still to be the rule not merely amongst most African races, but amongst the peoples, both

more and less civilised, of 'the East' generally, and to a certain extent in Australia and Polynesia, though it is rare amongst American Indians. That this custom was usual in Old Testament times is obvious from many references; the New Testament seems to indicate that monogamy was universal amongst the Jews of the 1st century, though the Talmud contains no positive prohibition against a plurality of wives. Christianity has never tolerated polygamy; even Concubinage (q.v.) has been always treated as sinful, and polygamy is a crime by the law of Christian states. Greeks and Romans did not practise polygamy within historical times; the ancient Germans were the only barbarians known to Tacitus who were content with a single wife. Moslem law and usage permit a man to have four wives, but such plurality is confined to the rich; poor men have seldom more than one wife (see MOHAMMEDANISM). There is no limit to the number of wives a Hindu may keep, without taking account of concubines. Instances still occur of a high-caste man of wealth having a hundred wives. But in this connection it should be remembered that in hot countries girls become marriageable at an early age, and soon lose their youth and attractiveness; a man's first wife may remain his confidante and real companion through life, though he provides himself with a succession of girl favourites. In China there is but one rightful wife in a household, though a man may, if he will, keep secondary wives or concubines.

In Christian countries, even in those where concubinage and adultery are lightly regarded and divorce very easily obtained, polygamy is dealt with as a criminal offence. In Britain and the United States Bigamy (q.v.) is severely punished; under the same head any polygamous union is included. Nevertheless there have occasionally been found divines to defend polygamy or something like it. The Anabaptists insisted on such freedom; Ochino (q.v.) wrote in defence of it. When in 1540 Philip the Magnanimous, the reforming landgrave of Hesse, resolved with the consent of his wife (then a confirmed invalid) to marry a second wife, Luther and Melanchthon approved the step 'as his personal friends, though not as doctors of theology;' and Bucer (q.v.) promoted, approved, and witnessed the bigamous union. The first wife survived the second marriage for nine years. As late as 1667, when Catherine of Braganza miscarried, some Anglican divines suggested polygamy as the best way of securing a direct heir to the throne. See also MILTON, p. 205.

Morganatic Marriage (q.v.) and Handfasting (q.v.) greatly simplified divorce, and often preceded a more binding and legitimate union; but another union at the same time was not compatible with either. In 1780 the Rev. Martin Madan, chaplain to the Lock Hospital in London, startled the world and raised a violent controversy by arguing in favour of polygamy as a means of diminishing prostitution and saving human souls from guilt; the work in which these views were advocated was called *Thelyphthora, or a Treatise on Female Ruin* (3 vols. 1780–81). In recent times the Mormons (q.v.) by their practice of polygamy created a troublesome question for the administrators of United States law; but in 1890 they agreed to cease from making plural marriages. It has always been a difficulty for Christian missionaries when converts with several wives desired baptism. As a rule the convert was treated as married only to the first wife in point of date, and was required absolutely to put away all the others—a rule that was inevitably harsh and inequitable in its operation. Bishop Colenso declined to make the convert part from wives he had married in good faith; so did the American missionaries in Burma; and M'Farlane, in *Among the Cannibals in New Guinea* (1888), says that he and the other missionaries of the London Missionary Society 'resolved not to interfere with those social relations in which the gospel found the people of New Guinea.' See ANTHROPOLOGY, FAMILY, MARRIAGE, HAREM, and the works cited there.

Polyglot (Gr. *polys*, 'many,' and *glōtta*, 'tongue') means a collection of versions in different languages of the same work, but is almost exclusively applied to manifold versions of the Bible. The Hexapla of Origen (q.v.) contained, besides the Hebrew text, several other Greek versions, but is not commonly reckoned among the polyglots. The most famous polyglots are (1) the Complutensian, published under the auspices of Cardinal Ximenes (q.v.) at Alcala (Lat. *Complutum*), in 6 vols. folio, 1502–17, with Hebrew, Greek, Chaldee (each with Latin versions), and the Vulgate Latin; (2) the Antwerp Polyglot, printed at the Plantin press, at the cost of Philip II. of Spain, in 1569–72, edited by Arias Montanus; (3) the Paris Polyglot, edited by Le Jay in 1645, in 6 splendid volumes; and (4) the London Polyglot, edited by Brian Walton, in 6 vols. folio, 1654–57, and containing the Bible, or parts of it, in nine languages. Of modern works of this kind the most convenient is Bagster's Polyglot, first published by Bagster at London in 1831 (new eds. 1874, &c.), which gives the Old Testament in eight languages (Hebrew, Greek, Latin, English, German, Italian, French, and Spanish), and the New Testament in nine (the Syriac version being added).

Polygnotus, a Greek painter who flourished in the middle of the 5th century B.C., was born in the isle of Thasos, and belonged to a family of painters. He was a friend of the Athenian general Cimon, and is said to have been attached to his sister, Elpinice. His principal works were at Athens, at Delphi, and at Platæa. In the first-named city he executed paintings in the temple of Theseus; in the Stoa Poikile (or Painted Portico), the Greek Princes assembled to judge of the Violation of Cassandra by Ajax; in the temple of the Dioscuri, the Rape of the Daughters of Leucippus; and in the Propylæa on the Acropolis, a series from the old Greek legends. At Platæa he painted, in the temple of Athena, Ulysses and the Slain Suitors of Penelope. His greatest work is said to have been in the Leschê, a court or peristyle at Delphi, built by the Cnidians, the walls of which he covered with a series representing the Wars of Troy and the Visit of Ulysses to the Lower World. Polygnotus was a great advance on any of his predecessors. He was the first who gave life, character, and expression to painting. Aristotle extols the dignity and beauty of his conceptions.

Polygon (Gr. *polys*, 'many,' *gōnia*, 'corner'), a plane figure, bounded by a number of straight lines; the name is conventionally limited to those plane figures whose bounding straight lines are more than *four* in number. Polygons of 5, 6, 7, 8, &c. sides are denominated pentagons, hexagons, heptagons, octagons, &c.; and when the number of sides exceeds twelve the figure is merely mentioned as a polygon of so many sides.

Polygonaceæ, a natural order of plants, mostly herbs, but including a few shrubs. The leaves are alternate, with stipules cohering around the stem, though sometimes reduced to a mere ring. The flowers are not unfrequently unisexual; the fruit generally a nut, often triangular, the seed with farinaceous albumen, which has an economic importance in buckwheat. The genus Polygonum comprises numerous species, of which several are natives of Britain; in North America

twenty-five species are found east of the Mississippi. Knot-grass (*P. aviculare*) is a very common British weed, and is found in cultivated and waste places in all parts of the world from the tropics to the Arctic regions. The stems of *P. amphibium*, an inhabitant of ponds and watery ditches all over Britain and Europe, central Asia, and North America, have been used as a substitute for sarsaparilla on the continent of Europe. *P. hydropiper*, often called Water Pepper, a plant common by sides of lakes and ditches in Britain and North America, is acrid enough to be used as a vesicant. Several species are occasionally used for dyeing, as the Spotted Persicaria (*P. persicaria*), a very common weed on dunghills and in waste places in Britain; but the only species really important on this account is that called Dyer's Buckwheat (*P. tinctorium*), a native of China, the cultivation of which has been successfully introduced in France and Flanders. It yields a blue dye scarcely inferior to indigo. *P. orientale* has long been occasionally cultivated in flower-gardens in Britain, and is quite hardy, although a native of the West Indies. The Bistort (q.v.) belongs to the genus. *Fagopyrum cymosum*, a species of buckwheat abundant on the mountains of the north of India, affords an excellent substitute for spinach. *Fagopyrum esculentum*, or *Polygonum Fagopyrum* (Buckwheat), is cultivated for the sake of its fruit, which furnishes a nutritious diet used in the countries of northern Europe. Thé Garden Sorrel (*Rumex acetosa*) and some other species of Rumex have a singular combination of properties in their roots and in their leaves. In the former there is greater or less astringency, due to the presence of tannic and gallic acid; the latter are more or less acidulous, owing to their containing oxalic acid. Rhubarb (q.v.) belongs to this natural order; so does the Dock (q.v.). The root of *Pterococcus aphylla*, a native of the sandy steppes of Siberia, when cut exudes a clear viscid gum similar to Tragacanth (q.v.), which swells in water and forms a mucilage of a brownish-yellow colour; it is eaten by the Kalmucks in times of scarcity. Its fruit, which is acid, is eaten to quench thirst. *Tripteris americana* and *T. Bonplandiana*, both natives of South America, are small trees with hollow branches which are the haunts of small venomous ants that shower themselves on the unwary who may attempt to shelter themselves under their shade. *Mühlenbeckia adpressa* is the Macquarie Harbour Vine of Tasmania, an evergreen climbing or trailing shrub of most rapid growth, sometimes 60 feet in length. It produces racemes of fruit somewhat resembling grapes or currants, the nut being invested with the large and fleshy segments of the calyx. The fruit is sweetish and subacid, and is used for tarts. *Coccoloba uvifera* is the Seaside Grape (q.v.) of the West Indies. See also CALLIGONUM.

Polyhymnia, one of the nine Muses (q.v.).

Polymerism. See ISOMERISM.

Polynesia (Gr. *polys*, 'many,' *nēsos*, 'island'), a term applied collectively by some writers to all the Pacific islands of strictly oceanic character—i.e. either of volcanic or coralline origin; by others restricted to the eastern groups inhabited by the brown Polynesian race. Here it will be taken in the broader sense so as to include all the Pacific lands east of the Philippines, New Guinea, and Australia, except Japan, the Kuriles, Aleutians, Queen Charlotte, Vancouver, Revillagigedo, and Galapagos, which are geographical dependencies of the surrounding Asiatic and American continents. These Polynesian, or 'South Sea' islands, as they are also called, are distributed over a vast space, stretching across a hundred degrees of longitude from New Britain (149° E.) to Easter Island (109° 17′ W.), and across seventy degrees of latitude from Hawaii (23° N.) to Stewart Island at the southern extremity of New Zealand (47° 20′ S.). But the aggregate extent of dry land in this boundless expanse of some 11 million square miles scarcely exceeds 170,000 sq. m., of which nearly two-thirds are comprised in the New Zealand Archipelago, while the total population is probably less than 1,500,000. See the map at WORLD, and also the physical map at AUSTRALIA.

Polynesia comprises the three broad divisions of Micronesia, Melanesia, and East Polynesia, which are determined partly by geographical position, and partly by ethnological conditions, and each of which is again subdivided into several secondary groups. Thus, Micronesia (Gr. *mikros*, 'small,' *nēsos*, 'island') lies in the extreme north-west almost entirely north of the equator, and consists exclusively of small volcanoes and atolls, forming the five archipelagoes of the Marianas (Ladrones), Pelew, (Palaos), Carolines, Marshall, and Gilbert, all inhabited by heterogeneous populations in which most of the oceanic and perhaps some of the continental elements are represented. So also Melanesia (Gr. *melas*, 'black') lies in the extreme west entirely south of the equator, and consists mainly of comparatively large upraised crystalline, coralline, and volcanic islands disposed in parallel chains from north-west to south-east, forming the eleven archipelagoes of the Admiralty, Bismarck (New Britain and New Ireland), D'Entrecasteaux, Louisiade, Solomon, Santa Cruz, Banks, New Hebrides, New Caledonia, Loyalty, and Fiji, all inhabited by the Melanesian or dark Oceanic race. Lastly, East Polynesia lies on both sides of the equator, mainly east of a line drawn from New Zealand between Fiji and Samoa to Hawaii, and consists of the twelve volcanic and coralline archipelagoes of Hawaii (Sandwich), Phœnix, Ellice, Tokelau, Samoa, Tonga, Kermadec, Austral (Tubuai), Cook, Tahiti, Tuamotu (Paumotu), and Marquesas, besides the large sedimentary and igneous region of New Zealand and numerous sporadic islets, such as Norfolk, Chatham, Rapaiti, Easter, Manihiki, Tongareva, Uvea, and many others. This division is the exclusive domain, apart from recent white immigrants, of the large brown race, commonly called 'Polynesians' in a special sense.

Subjoined is a table of these multitudinous insular groups, with their areas, populations, and political status.

Group.	Area in sq. m.	Pop.	State.
I. MICRONESIA—			
Mariana	450	10,000	Germany and U.S.
Pelew	200	12,000	Germany.
Caroline	400	30,000	Germany.
Marshall	160	11,000	Germany.
Gilbert (Kingsmill)	170	41,000	England.
II. MELANESIA—			
Admiralty	770	2,000	Germany.
Bismarck	16,000	70,000	Germany.
D'Entrecasteaux	1,100	1,000 (?)	England.
Louisiade	870	2,000 (?)	England.
Solomon	16,300	175,000	England and Ger.
Santa Cruz	200	5,000	England.
Banks	190	4,500	England.
New Hebrides	5,000	62,000	Independent.
New Caledonia	6,500	43,000	France.
Loyalty	1,100	20,000	France.
Fiji	8,000	125,000	England.
III. EAST POLYNESIA—			
Hawaii	6,700	81,000	United States.
Phœnix	15	60	Independent.
Ellice	14	3,300	England.
Tokelau	12	520	England.
Samoa	1,000	35,000	U.S., Ger.
Tonga	450	30,000	England.
Kermadec	40	100	England.
Austral	105	1,400	France.
Cook (Hervey)	140	11,500	England.
Tahiti (Society)	600	17,000	France.
Tuamotu (Low)	360	5,600	France.
Marquesas	480	6,000	France.
New Zealand	104,000	604,000	England.

Lying almost entirely within the tropics, and consisting nearly everywhere of igneous or coralline groups exposed to the same atmospheric and marine currents, Polynesia presents great uniformity in its climatic and biological conditions. In these respects, however, New Zealand belongs to a separate world, thanks to its large extent, lofty ranges, different geological history, and high southern latitude. But even in Fiji, Tahiti, Samoa, the Solomon and Hawaiian groups, with volcanic cones ranging from 1000 to nearly 14,000 feet, less variety is presented by the different local floras than might be expected from their great altitude. Almost everywhere the prevailing winds are the moist south-east trades, which in summer veer round to the west and north-west. But these winds also bring moisture-bearing clouds, so that the rainfall is generally high, in the Solomons excessive (150 inches), in Hawaii 60 to 80, and in New Caledonia over 40. But many of the atolls, being too low to arrest the currents, receive very little moisture, and in some places constitute a rainless zone, as indicated by the accumulated deposits of guano. The mean temperature is about 70° F. both in Hawaii and New Caledonia (about the two tropics), with an extreme range from 50° to 90° F. But the climate, except in New Caledonia and New Zealand, is everywhere relaxing, and in the Solomons and other large islands malarious up to considerable altitudes.

In the coralline groups the flora is essentially oceanic, the prevailing species being the cocoa-nut and one or two other palms, the pandanus and bread-fruit tree, and such edible roots as yams, taro, and sweet potatoes. Besides these forms, the large archipelagoes have a rich forest vegetation, mostly belonging to the Papuasian and Australian zones, with some American and a few indigenous plants. Hence the prevalence of casuarinas, dammaras, araucarias, tree-ferns, besides myrtles, ebony, and the banyan fig. Highly specialised forms are the New Caledonian *niauli* (*Melaleuca leucadendron*), which yields the cajeput-oil, and the Hawaiian oleaginous *kukiu* and gigantic *halapepe* (Branchleya), with foliage like that of the pandanus. As many as 1300 distinct species have been discovered in New Caledonia, and nearly 1400 in Fiji, of which 1100 are phanerogamous.

In contrast with the relatively rich flora is the remarkably poor fauna, especially in mammals. The dog and pig were found both in the Solomons and Hawaii at the time of their discovery; but both appear to have been introduced in comparatively recent times. The only undoubtedly indigenous mammals in these and the other Polynesian groups are two or three species of rodents (rats and mice) and a few varieties of the bat family. Even reptiles and insects are rare, being chiefly represented by three small lizards in Hawaii, one snake, one scorpion, one centipede, and a spider in New Caledonia, a few snakes and frogs in Fiji, and in East Polynesia by only one venomous animal, a centipede. Fiji is the easternmost limit of the frog and the Solomons of the crocodile, which here adapts itself both to fresh and salt water about the rivers and estuaries. Birds are everywhere more numerous, 107 species occurring in New Caledonia, 46 in Fiji, and 40 in Hawaii, these last including the oo (*Moho nobilis*), whose lovely black and yellow plumage is used for decorating royal mantles.

In recent times no branch of ethnology has been more carefully studied than that which deals with the origin, migrations, physical features, languages, and traditions of the Oceanic peoples. But so intricate are their mutual relations that the difficult anthropological and linguistic problems suggested by a comparative study of these peoples are still far from solved. There is, however, a general consensus that Polynesia has been occupied from prehistoric times by two distinct races, the dark Melanesians, who belong to the same stock as the Papuans of New Guinea and Malaysia, and the brown Polynesians, called also Mahori and Sawaiori, whose racial affinities have not been satisfactorily determined. By different writers they have been allied to the Mongoloid Malays, to the Aryans or Caucasians, to the American aborigines, and even to the Melanesians. But the difference between the Polynesians and Melanesians must be regarded as fundamental. The former are brachycephalous (round-headed, with high cephalic index), orthognathous, narrow-nosed, of a light-brown *café-au-lait* colour, with round orbits and black lank hair, and next to the Patagonians the tallest people on the globe (mean height, 5 feet 10 inches). The Melanesians are dolichocephalous (long-headed, with the lowest cephalic index of any race), prognathous, broad-nosed, of a sooty black colour, with low orbits, black frizzly hair, and low stature (mean height, 5 feet 5 inches).

The Melanesians appear to be the indigenous element in the Pacific, where they formerly occupied a much wider domain than at present, for traces of black blood are found in Samoa, New Zealand, and even as far east as the Marquesas (Whitmee). They also stand at a lower stage of culture, being undoubted cannibals, in many places head-hunters, extremely savage, blood-thirsty and treacherous, scarcely recognising any hereditary chiefs, and often forming independent hostile groups at perpetual feud with their neighbours.

The Polynesians, who closely resemble the Indonesians of the Malay Archipelago (see MALAYS), seem to be later arrivals almost certainly from Malaysia to Samoa, whence they gradually spread from island to island over all the eastern archipelagoes, more recently sending colonies westwards to Melanesia and even to New Guinea. Hence Sawaiori settlements and mixed Sawaiori-Melanesian communities are now found in the eastern parts of Fiji, in the New Hebrides (Niuē, Futuna, Mel, and Fil), in the Loyalty group (Uvea), in British New Guinea (Motu), and generally in Micronesia. That Samoa was the centre of dispersion is shown by the recurrence of such geographical terms as Samoa and Savaii (originally Savaiki), the largest island of the archipelago, under diverse dialectic forms (Hamoa, Amoa, Hawaii, Havaiki, Hawaiki, Avaiki), either in the geographical nomenclature or in the traditions and mythologies of all the Polynesian islanders from New Zealand to Hawaii.

In Easter Island (Rapanui) and the Carolines (Ponapé, Lelé, Ualan) are found numerous cyclopean monuments, huge monolithic statues, paved avenues, ramparts or walls of basalt blocks over 30 feet long, brought from great distances. None of the present races could erect such structures as these, all memory of which has died out. They have been referred to the cultured peoples of America, and the features of the Easter Island (q.v.) statues are said to resemble the Bolivian Aymaras, though others have recognised a Papuan cast in the specimens preserved in the British Museum. Skulls of a Papuan type have also been found in Easter Island, but if the monuments were erected by these natives, it must have been under the direction of builders such as the Hindu missionaries who raised the stupendous temples of Java and Indo-China by training Malay and Cambodian craftsmen for the work.

Nearly all the Pacific languages appear to be members of the great Malayo-Polynesian family, which stretches across two oceans, from Madagascar to Rapanui. However it is to be explained, the fact is now established that both the dark and

brown peoples speak idioms derived from a common stock; and Mr Codrington has even shown that the Melanesian are of a more archaic type than the Polynesian tongues. Perhaps this is the most inexplicable of all the problems presented by the Oceanic peoples, for here anthropology and philology are found to be in direct antagonism. At first sight it would appear as if the lower had imposed its speech on the higher race, by whom it became profoundly modified both in its phonetic system and grammatical structure. But the reverse and less violent process is conceivable, and it may be assumed that during their endless migrations over the Pacific the more enterprising and intelligent Polynesians transmitted their speech to the more passive Melanesians at a very remote period, the former afterwards modifying it in the direction of greater simplicity and harmony, the latter preserving it in its more pristine inflectional form.

For over a century the Oceanic peoples have been in contact with Europeans, and nearly all the Polynesians, as well as many of the Melanesians, profess some form of Christianity—the first mission established being that to Tahiti in 1797 by the London Missionary Society. But as western influences increase the races themselves appear to decrease. Thus, the population of Hawaii had fallen from about 300,000 at the time of Cook's visit (1778) to 40,000 in 1884; the Maoris of New Zealand, who numbered probably 400,000 in 1769 (Cook's first visit), were reduced to 42,000, including half-castes, in 1886, and the Tahitians from 240,000 in 1776 to less than 10,000 in 1888. Here and there the returns show an apparent increase, as in some of the Ellice and Marshall islands, but only amongst the half-castes. Everywhere the pure Polynesian race seems to be rapidly disappearing, a phenomenon attributed partly to the introduction of alcoholic drinks, partly to the abrupt change of habits, dress, diet, &c. enforced or encouraged by the missionaries, but mainly to the ravages of leprosy, smallpox, syphilis, measles, and especially pulmonary affections, by which whole communities have been decimated.

Formerly the political organisation was based on a distinction between two classes, the nobles and the common people. The Maoris had developed a sort of democracy; but elsewhere the archipelagoes constituted one or more monarchies of a somewhat feudal character, with powerful hereditary rulers under a king, whose authority had been much reduced in Samoa, the Marquesas, and some other groups. Their subjects were a gay, pleasure-loving people, engaged chiefly in fishing, agriculture, and navigation. Their diet was largely vegetarian (yams, taro, batatas, bananas, cocoa-nuts, &c.), varied with fish, pork, poultry, and, in some places, human flesh. Human victims were also offered on solemn occasions, and a prominent feature of the primitive religion was the so-called *Tabu* (q.v.), in virtue of which certain persons and objects acquired a sacred character. But there was nowhere a distinct sacerdotal class, and most of the old beliefs had resolved themselves into a system of ancestor-worship. Other distinctive institutions were certain orders of knighthood, secret societies with peculiar semi-religious rites, and tattooing, which, especially in Micronesia, acquired the character of a fine art, rivalling the Burmese and Japanese systems in its elaborate designs and skilful execution. Few other arts were practised, and letters were unknown, although a national folklore, tolerably rich in historic legends and myths, was orally preserved, and has now been mostly committed to writing by European scholars.

See CORAL, and the articles on the several Polynesian islands or groups of islands; and for the first navigators in Polynesia, see GEOGRAPHY, PACIFIC OCEAN in this work. See also Ellis, *Polynesian Researches* (1829); Reybaud, *La Polynésie* (1843); Sir George Grey, *Polynesian Mythology* (1855); De Quatrefages, *Les Polynésiens et leurs Migrations* (1866); Pritchard, *Polynesian Reminiscences* (1866); Angus, *Polynesia, or the Islands of the Pacific, &c.* (1867); Waitz-Gerland, *Anthropologie der Naturvölker*, vol. vi. (1872); Moresby, *New Guinea and Polynesia* (1877); Fornander, *An Account of the Polynesian Race, &c.* (1878–86); Gill, *Historical Sketches of Savage Life in Polynesia* (1880); Lesson, *Les Polynésiens, &c.* (1880–87); Keane, *Inter-Oceanic Races and Languages* (1880); *Novara* and *Challenger* Reports; R. H. Codrington, *The Melanesians* (1891); and Guillemard on *Malaysia and the Pacific Archipelagoes* (1895) in the new edition of 'Stanford's Compendium.'

Polyp, a name usually applied to an animal like the fresh-water Hydra or like the Sea-anemone, having a tubular body and a wreath of many tentacles around the mouth. The name is equally applicable to an isolated individual or to a member (zooid or 'person') of a colony. Thus, the individuals which make up a zoophyte or a coral colony are called polyps, and the term is seldom used except in reference to Cœlenterate animals. But the history of the word has been strange. In Greek and Latin works on natural history the term *polypous* or *polypus* is usually applied to the octopus (*poulpe*), or some other cuttle-fish, though sometimes to the many-footed wood-louse, Oniscus. Réaumur and Jussieu were the first to apply the word to zoophytes and the like; Lamarck used it more loosely, but gradually it has been narrowed to the signification above noted. See ANEMONE, CŒLENTERATA, CORAL, HYDRA, HYDROZOA, &c.; and POLYPUS, for the surgical use of the term.

Polyphemus, in the Homeric mythology, the son of Poseidon and the nymph Thoosa, the most celebrated of the fabulous Cyclopes (q.v.), who inhabited the island of Sicily. He was of immense size, and had only one eye. When Ulysses landed on that island he entered the cave of Polyphemus with twelve companions, of which number this tremendous cannibal ate six. The others stood expecting the same fate, but their cunning leader made Polyphemus drunk, then burned out his single eye with a burning pole, and so escaped, leaving the blinded monster to grope about in the darkness.

Polyphonic (Gr. *polys*, 'many,' and *phōnē*, 'voice'). When a musical composition consists of two or more parts, each of which has an independent melody of its own, it is said to be polyphonic, in opposition to a homophonic composition, consisting of a principal part with a leading idea, and accessory parts employed to strengthen it. Each part of a polyphonic composition aims at melodic perfection, and, while supporting the other, has an equal share in the entire effect. A Fugue (q.v.) is the most perfect example of polyphonic composition.

Polypodium (the Greek name, as old as Theophrastus, was *polypodion*, from *polys*, 'many,' and *podion*, 'a little foot'—indicating the foot-like appendage of the rhizome, not the leaf), a genus of Ferns, with spore-cases on the back of the frond, distinct, ring-shaped, in roundish *sori*, destitute of *indusium*. It is the largest genus of the Filices, comprising over 450 species; and amongst them are plants of different modes of growth, of different venation, and from almost all climates. Several species, differing very considerably in appearance, are natives of Britain, where no fern is more common than *P. vulgare*. It grows on rocks, trees, dry banks, &c., and has fronds 2 to 18 inches long, deeply pinnatifid, with large sori. *P. dryopteris*, with delicate ternate bipinnate fronds, is a fine orna-

ment of many dry stony places in Scotland. *P. calaguala*, a native of Peru, is said to possess

Polypodium:
1, *Polypodium dryopteris*; 2, *P. vulgare*.

important medicinal properties—solvent, deobstruent, sudorific, &c.

Polyporus. See AMADOU, and DRY ROT.

Polyp'terus, a genus of Ganoid fishes, of which only one species (*P. bichir*) is known. It lives in the Nile and western rivers of tropical Africa. It may attain a length of 4 feet, and is esteemed as food. Very characteristic is a series of dorsal spines, with attached finlets, which extend almost the entire length of the back. Of its life very little is known. The only nearly allied living form is *Calamoichthys calabaricus* from Old Calabar.

Polypus, in Surgery, is an ancient term employed to signify any sort of pedunculated tumour attached to the surface of a mucous membrane, to which it was supposed to adhere like a many-footed animal, as its name indicates. The most common seats of polypus are the nostrils and the uterus; but these tumours are also found in the rectum, the larynx, and the external auditory passage of the ear. The only satisfactory mode of treatment consists in their removal, which must be effected in various ways, according to their position, as by the forceps, écraseur, ligature, &c.

Polytechnique, or POLYTECHNIC SCHOOL (Gr. *polys*, 'many,' *tcchnē*, 'art'), is an institute in which the technical sciences that rest in great part upon a mathematical basis, such as engineering, architecture, &c., are taught. The first school of the kind was established in Paris (1794) by the National Convention, under the name of School of Public Works. No students were admitted but those who intended to enter the public service, especially the corps of civil and military engineers and the artillery. The Polytechnic School, as it was called from 1795, has been repeatedly reorganised as the different political parties have succeeded to power. At the present time it is the institute in which France trains her artillery and engineer officers, her naval engineers, her directors of roads and bridges, and of mines, her telegraph officers, in short, all her officials who require to know something of the higher branches of technical science. Germany too has her polytechnics. Those that came into being during the first half of the 19th century were in great part training-schools for the higher branches of the industrial arts; but since Zurich established (1856) a polytechnic modelled on the plan of the German universities, most of the German polytechnics have followed suit. Of these establishments, thus increased in scope (now called also *Technische Hochschulen*), Germany has nine or ten, and Austria-Hungary half a dozen; though Germany has also several other colleges that might fairly claim the name of *Polytechnikum* in the old sense. The nine technical colleges of Berlin, Hanover, Aix-la-Chapelle, Munich, Dresden, Stuttgart, Carlsruhe, Darmstadt, and Brunswick have some 550 teachers and 6000 pupils—the chief departments of instruction being architecture, civil engineering, machine-making, shipbuilding, chemistry, and metallurgy. In America the oldest institutions of the kind are the Rensselaer Polytechnic Institute, at Troy, New York, and the Franklin Institute, at Philadelphia, both founded in 1824. There are now nearly a hundred technical schools in the United States, more than half of them endowed with a national land-grant. See TECHNICAL EDUCATION; also ART; and Pinet, *Histoire de l'École Polytechnique* (1886).

Polytheism. See RELIGION.

Polytrichum, a genus of Mosses (q.v.).

Polyzoa, or BRYOZOA, a class of small animals which, with one exception, form colonies, and are almost always fixed. Most familiar are the sea-mats or horn-wracks (Flustra), cast-up pieces of which are abundant on the beach. On these will be seen the hundreds of separate chambers in which the minute individuals live. Each individual has a sac-like or cup-shaped body, traversed by a food-canal bent like a U, crowned around the mouth by a wreath of tentacles, controlled by a single nerve-centre. The cuticle which surrounds the body is usually horn-like, not unfrequently calcareous (Cellepora, Lepralia, &c.), and sometimes gelatinous (Alcyonidium, Lophopus). The individuals of a colony are not always all alike; thus, some of them are occasionally modified into strange birds'-beak-like or whip-like structures. All Polyzoa multiply by budding, and thus the colonies increase. The individuals in the older parts of the colony usually degenerate or die. Fresh-water forms reproduce by peculiar winter-buds or statoblasts, which are liberated on the death of the parent, are floated away by currents, and after a winter's quiescence develop in spring. But all Polyzoa also reproduce sexually; the sexes may be separate or united; the larvæ developed from the eggs are free-swimming. The Polyzoa used to be ranked with zoophytes (among the Hydrozoa), but the individual animals are much more complex and are independent of one another. Often they are called molluscoid, because of apparent affinities with lamp-shells or Brachiopods, which used to be regarded as allied to molluscs. Most modern zoologists rank them as a distinct but heterogeneous class in the great assemblage of 'worms' or 'Vermes.' Representative genera are Cristatella, Lophopus, Plumatella—in fresh water; Flustra, Membranipora, Alcyonidium, Cellepora—marine; Pedicellina and Loxosoma—two marine genera, simpler than the others, the latter non-colonial. Rhabdopleura, a remarkable genus sometimes included in this class, shows at least hints of vertebrate affinities.

See Allman, *British Fresh-water Polyzoa* (Lond. 1886); Busk, *Challenger* Report, X. (1884); Hincks, *British Marine Polyzoa* (Lond. 1880); E. Ray Lankester, article 'Polyzoa' in *Ency. Brit.*

Pomaceæ, or POMEÆ, according to some botanists, a natural order of plants, but more generally regarded as a sub-order of Rosaceæ (q.v.). The plants of this order are all trees or shrubs, abundant in Europe, and chiefly belong to the

temperate and colder regions of the northern hemisphere; they are rare in very warm climates, and are not found at all in the southern hemisphere. They have the botanical characters described in the article Rosaceæ (q.v.), and in addition are distinguished by having the tube of the calyx more or less globose, the ovary fleshy and juicy, lined with a thin disc, its carpels adhering more or less to the sides of the calyx and to each other; the fruit a *Pome* (q.v.), 1- to 5-celled, in a few instances spuriously 10-celled; the ovules in pairs, collateral. Many of the species are prized for the beauty and fragrance of their flowers, some produce valuable timber; but the order is chiefly remarkable as producing a number of the very finest fruits of temperate climates. See Apple, Pear, Quince, Medlar, Loquat, Hawthorn, Cratægus, Amelanchier, Rowan, Service.—There are about 200 known species.

Pomade, or Pomatum, is a preparation of fine inodorous fat, such as lard or suet, used instead of liquid oil for the hair. It may be perfumed with various essences.

Pombal, Sebastian Joseph de Carvalho e Mello, Marquis of, the greatest of Portuguese statesmen, was born 13th May 1699, at the castle of Soure, near Coimbra. In 1739 he was appointed ambassador in London, and six years later was sent to Vienna in a similar capacity. Just before Joseph I. ascended the throne of Portugal (1750), Pombal was appointed secretary for foreign affairs. Among his first acts was to re-attach to the crown a number of domains that had been unjustly alienated. When the great earthquake happened at Lisbon in 1755 Pombal displayed great calmness and fertile resource, so that next year the king made him prime-minister. He crushed a revolt instigated by the great nobles and the Jesuits, and in 1759 banished the latter from the kingdom. Then he abolished slavery in Portugal, set himself to establish good elementary schools, and published a new code of laws. Besides this, he effected the reorganisation of the army, the introduction of fresh colonists into the Portuguese settlements, the establishment of an East India Company, and another for Brazil. The tyranny of the Inquisition was broken. Agriculture, commerce, and the finances were all improved. In 1758 he had been made Count of Oeyras, and in 1770 he was created Marquis of Pombal. On the accession of Joseph's daughter, Maria I. (in 1777), who was under clerical influence, Pombal, who had himself been high-handed, if not despotic, especially towards the Church, was banished from court, while many of his institutions were abolished. He died at his castle of Pombal, 8th May 1782.

See Life by G. Moore (1819); John Smith, *Memoirs of Pombal* (2 vols. 1843); Carnota, *Marquis Pombal* (Eng. trans. 1871); and Carayon, *Prisons du Marquis de Pombal*—his diary (Paris, 1865).

Pome (Lat. *pomum*, 'apple'), the form of Fruit (q.v.) produced by the Pomaceæ (q.v.)—a fleshy, indehiscent, syncarpous fruit, with calyx attached.

Pomegranate (*Punica granatum*), a fruit much cultivated in warm countries, and apparently a native of the warmer temperate parts of Asia, perhaps also of the north of Africa. It has been cultivated in Asia from the most ancient times, and is frequently mentioned in the Old Testament. It has long been naturalised in the south of Europe. In a wild state the plant is a thorny bush, in cultivation it is a low tree, with twiggy branches, flowers at the extremities of the branches, the calyx red, the petals scarlet. It is generally referred to the natural order Myrtaceæ. The calyx is leathery, tubular, 5- to 7-cleft; there are 5 to 7 crumpled petals; the fruit (technically called *balausta*) is as large as a medium-sized orange, having a thick leathery rind of a fine golden yellow, with a rosy tinge on the sunny side, not bursting when ripe; the cells filled with numerous seeds, each of which is surrounded with pulp, and separately enclosed in a thin membrane; the upper and lower series of carpels being differently attached. Thus the pomegranate appears to be formed of a great number of reddish berries packed together and compressed

Pomegranate (*Punica granatum*).

into irregular angular forms. The pulp is sweet, sometimes subacid, and of a pleasant delicate flavour, very cooling, and particularly grateful in warm climates. It is often used for the preparation of cooling drinks. A kind of pomegranate without seeds is cultivated and much prized in India and Persia. Pomegranates have long been imported in small quantities into Britain from Portugal and the north of Africa, but have never become an article of general demand and commercial importance like oranges. There is an ornamental variety of the pomegranate with double flowers. The rind of the fruit is very astringent, and a decoction is used as a gargle in relaxed sore throat, and as a medicine in diarrhœa, dysentery, &c. Deriving its astringency from tannin, it is used to tan leather. The finest Morocco leather is said to be tanned with it, and small quantities are imported into Britain from the north of Africa for the preparation of the finest kinds of leather, under the name of *Pomegranate Bark*. The bark of the roots is used as an anthelmintic, and is often successfully administered in cases of tapeworm. It contains a peculiar principle called *punicin*, having the appearance of an oleo-resin, an acrid taste, and affecting the nostrils like Veratria (q.v.). Its value was known to the ancients, and it has long been in use in India. The pomegranate tree is occasionally cultivated in hothouses or greenhouses in Britain. It bears the winters of the latitude of London in the open air, and is very ornamental, but the fruit is worthless. In some parts of the south of Europe it is used as a hedge-plant. In northern Mexico it grows to great perfection, and in some of the southern states of the American Union; even as far north as New York it will, if protected in winter, bear fruit, and in some seasons ripen it.

Pomerania (Ger. *Pommern*), a province of Prussia, bounded N. by the Baltic, E. by West Prussia, S. by Brandenburg, and W. by Mecklenburg. Area, 11,620 sq. m. It is one of the lowest and flattest regions in Germany, and has few hills of even moderate height, but numerous lakes and ponds. The river Oder divides Hither Pomerania (next Mecklenburg) from Farther Pomerania. The shores of the latter are lined with sand-dunes. The islands of Wollin and Usedom form the northern side of the Stettiner Haff (Lagoon); and farther to the north-west lies the island of Rügen. Pomerania is essentially an agricultural province, more than 55 per cent. of the total area being in tillage, whilst meadows cover another 19½ per

cent., and forests nearly 20 per cent. Rye and potatoes are the principal products; in a secondary degree come wheat, barley, oats, flax, beet-root, tobacco, hops, and fruit. More than 55 per cent. of the soil is owned by the nobility, as in Mecklenburg (q.v.). Commerce flourishes in the coast towns, Stettin and Stralsund being the most important. Apart from shipbuilding, machine-works, and the manufacture of sugar, chemicals, bricks, &c., which are carried on principally in the coast towns, the only industries are paper, tobacco, glass, and wooden wares. The fisheries are valuable. Much poultry is reared, especially geese, in Farther Pomerania. Greifswald in this province is the seat of a university; Stettin is the capital. Pomerania sends fourteen members to the imperial diet, and twenty-six to the Prussian Lower House. Pop. (1890) 1,520,889. See PRUSSIA.

Pomerania formed a part of the territory of the ancient Vandals. When they moved south in the 5th century, it was occupied by Slavic tribes, one of whom was called Pomerani; hence the name of the region. From about 1100 it had its own line of princely rulers, and about 1124 it adopted Christianity in consequence of the preaching of Bishop Otto of Bamberg. The native princes assumed the title of duke in 1170 and joined the German empire, being put under the suzerainty of Brandenburg. The duchy was overrun by the Imperialists in the Thirty Years' War, and Wallenstein besieged Stralsund; they were followed by the Swedes, who established themselves permanently in Hither Pomerania and in several towns of Farther Pomerania. In 1637 the last duke of the native dynasty died, whereupon Brandenburg claimed the duchy; the Swedes, however, stuck to what they held until 1720, and certain districts in Hither Pomerania were not given up to Prussia until 1815. See Histories by Kantzow (1835), Sell (3 vols. 1819–20), Fock (6 vols. 1861–72), and Klempin (3 vols. 1868–88).

Pomeroy, capital of Meigs county, Ohio, between the Ohio River and a range of precipitous hills, 133 miles by rail SE. of Columbus. The mining of coal and the manufacture of salt are the chief industries. It also contains foundries, a woollen-factory, &c. Pop. (1870) 5824; (1890) 4726.

Pomfret. See PONTEFRACT.

Pomona, the Roman divinity of the fruit (*pomum*) of trees. She was beloved by several of the rustic divinities, as Sylvanus, Picus, and Vertumnus. Propertius tells us that the last, after vainly trying to approach her under various forms, at last succeeded by assuming the figure of an old woman. In this guise he recounted to her the lamentable histories of women who had despised love, and, having touched her heart to pity, suddenly transformed himself into a blooming youth. Varro tells us that at Rome the worship of Pomona was under the care of a special priest, the *flamen Pomonalis*. In works of art she was generally represented with fruits in her lap, or in a basket, with a garland of fruits in her hair, and a pruning-knife in her right hand.

Pomona, or MAINLAND. See ORKNEY.

Pompadour, JEANNE ANTOINETTE POISSON, MARQUISE DE, the most famous among the mistresses of Louis XV., was born in Paris, 29th December 1721. She was baptised as the child of François Poisson and his wife Madeleine de la Motte, but it was suspected that her father was Le Normant de Tournehem, a wealthy *fermier-général*, who provided for her education. She grew up a woman of remarkable grace and beauty, devoted to music and painting, and charming every one by her vivacity and wit. But her mind was early depraved by her mother, who constantly dinned into her ears that she was 'un morceau de roi,' and habituated her to see in the rôle of king's favourite the ideal of feminine ambition. In 1741 she was married to her protector's nephew, Le Normant d'Etioles, and soon became a queen of fashion in the financial world of Paris. But neither this nor a devoted husband's love could satisfy her heart, and, as it was impossible to hope for an introduction at court, for two years she sought to attract the eye of the king by waylaying him when he went out hunting. At length in February 1745 she attained her object at a ball given by the city on the occasion of the dauphin's nuptials, and ere long she was installed at Versailles, and ennobled by the title of Marquise de Pompadour. Her husband, to whom she had already borne a daughter, was removed from Paris, but later had his loss recouped with lucrative offices; her brother was afterwards made Marquis de Marigny. Ere long she assumed the entire control of public affairs, the king being merely an indolent *fainéant* who assisted at the spectacle of his reign without even taking an interest in it. For twenty years the mistress swayed the whole policy of the state, and lavished its treasures on the gratification of her artistic tastes, and in carrying out her own ambitious schemes. She reversed the traditional policy of France because Frederick the Great lampooned her, and the proud Maria Theresa addressed her in a letter under the royal style as *Ma cousine*. She filled all public offices with her nominees, corresponded with the generals in the field, and made her own creatures ministers of France, the Abbé de Bernis and the Duc de Choiseul. Her policy was disastrous, her wars unfortunate; still the ministry of Choiseul was the only fairly creditable portion of the reign, which owed to her twenty years of relative dignity. She was a lavish patroness of the arts, and heaped her bounty upon poets and painters, yet did not escape showers of lampoons—the famous *Poissardes*, for a suspected share in which many a wit went to the Bastille. She loved china, fine buildings, books, and sumptuous bindings, and it is said printed with her own hands a fine edition of the *Rodogune* of Corneille. Indeed, she was an artist in everything—'elle était des nôtres,' as Voltaire said truly when he heard of her death. The king remained faithful to her from habit rather than affection, and from the rôle of mistress she passed into that of *amie nécessaire*, and retained her difficult position to the end, by relieving him of all business, by diverting him with private theatricals in her famous 'théâtre des petits cabinets,' where she acted charmingly, and at last even by countenancing his infamous debaucheries and providing him with mistresses too insignificant to be rivals. She herself said with the pathos of truth, 'ma vie est un combat,' and at last her nerves gave way under the strain, and after a languor of twenty days she died, 15th April 1764. She met the inevitable with that queenly dignity that marked everything she did. Her breath fled on the wings of a playful sally—'Stay, Monsieur Curé,' she said to the priest who was leaving her room, 'wait a little; we shall go out together.'

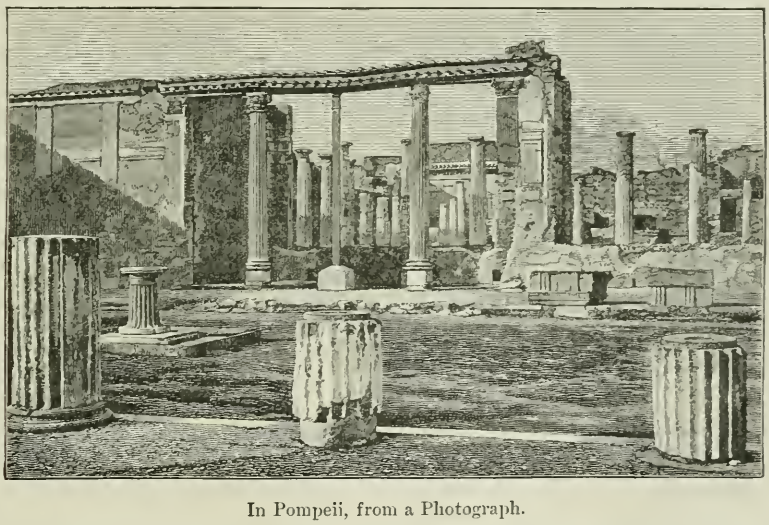
Madame de Pompadour was the last mistress of the king worthy of the name; the descent from her reign of grace and decorum to the boisterous vulgarities of Dubarry was profound. She was 'froide comme une macreuse,' says Madame du Hausset, her femme-de-chambre, in her silly but interesting memoirs, and there can be no doubt that throughout life ambition was the one passion of her heart. She secured her reign till her last hour—no sooner had she closed her eyes than she was forgotten.

The *Mémoires* (Liége, 1766) attributed to her are of no value. See the studies by Capefigue (1858) and Campardon (1867); E. and J. de Goncourt, *Les Maîtresses de*

Louis XV. (vol. ii. 1860); Beaujoint's *Secret Memoirs of La Marquise de Pompadour* (1885); but especially her *Correspondance*, with her father and brother, edited by Malassis (1878), and with the Comte de Clermont, edited by Bonhomme (1880).

Pompeii, a seaport at the mouth of the Sarnus, on the Neapolitan Riviera, founded about 600 B.C. by the Oscans, and, after them, occupied by the Tyrrheno-Pelasgians, and by the Samnites, till these, about 80 B.C., were dispossessed by the Romans. From that time down to its destruction, 79 A.D., it became (with Herculaneum) a sort of Rome-super-Mare, frequented by the aristocracy, if not by Caligula and Nero, in whose honour it erected triumphal arches. Fed from the capital with every luxury and distinction, it included temples in which the inhabitants were encouraged to make costly sacrifices with all their adjuncts of festivity and banqueting; indeed, its public monuments, out of all proportion to its size, were in number and magnificence such as we can now but dimly estimate. On February 5, 63 A.D., by an earthquake in the vicinity, these buildings were all but levelled with the ground, and some years elapsed ere the fugitive citizens recovered confidence enough to re-occupy and rebuild what was once Pompeii. Reconstruction was carried out with a haste and disregard of architectural law contrasting strongly with the earlier work—the Forum especially exhibiting the inferiority of its Roman to its Greek builders. Tawdriness replaced simplicity of decoration—the columns, capitals, and cornices being ornamented with reliefs in stucco picked out with parti-coloured designs, while private houses, fantastically restored and adorned, infringed every artistic or æsthetic canon to favour the grotesque style of the Decadence. Revolutionised as it was for the worse, the city, however, retained a good deal of Greek character and colouring, and had relapsed into more than its former gaiety and licentiousness, when on the 23d August (or, more probably, on the 23d November) 79, with a return of the shocks of earthquake, Vesuvius was seen to throw up a column of black smoke expanding like some umbrella-pine of the neighbourhood, till it assumed the proportions of a great swarthy cloud, dense with ashes, pumice, and red-hot stones, settling down on the doomed cities with a force increased by the rain-torrents that intermittently fell. Amid the impenetrable gloom that veiled land and sea, the panic of the citizens was aggravated by repeated shocks of earthquake, and for three days the flight continued till Pompeii was abandoned by all who could effect their escape. By the fourth day the sun had partially reappeared, as if shining through a fog, and the more courageous of the citizens began to return for such of their property as they could disinter. Much was doubtless recovered or possibly stolen; but the desolation and distress were such that the reigning emperor Titus organised relief on an imperial scale, and even undertook the clearing and rebuilding of the city. This attempt was soon abandoned, and Pompeii remained a heap of hardened mud and ashes, gradually overgrown with grass—the wall of the great theatre and the outline of the amphitheatre alone marking its site—till 1592, when the architect Fontana, in cutting an aqueduct, came on some ancient buildings. These were long believed to mark the old Stabiæ; and only in 1748, under the Bourbon Charles III., were they recognised as part of Pompeii. Unsystematic, unscientific excavations proceeded fitfully till 1860, when the Italian kingdom took in hand the unearthing of the city. This was carried out with admirable ingenuity, care, and success—all treasure-trove being vigilantly preserved, and an archæological record kept by the official excavators Fiorelli and Ruggiero, till now Pompeii possesses a distinction unknown to it in the zenith of its imperial favour, and attracts the pilgrim from every clime for the object-lessons it is unique in affording as to the public and private life of antiquity.

We cannot give more than the merest indication of the outline and distribution of Pompeii as now exposed. In form an irregular ellipse, extending from east to west, in circumference about 2843 yards, it had eight gates to which archæology has given names mostly conjectural. It had outgrown its walls, however, particularly towards the sea, and developed considerable suburbs. Its most important part—not quite one-half, including Forum, adjacent temples and public buildings, two theatres with colonnades, amphitheatre, and many private houses—has already been exhumed, and five main streets made out and (provisionally) named. It has been divided, by official arrangement, into nine *regiones* (quarters), seven of them wholly or partially excavated, and each is subdivided into *insulæ* (blocks), bounded by four streets and provided each with a number, as are also the streets of each quarter. A *trottoir* borders the streets, which are straight and narrow—the broader 24 feet wide, the narrower 14 feet only—and admirably paved with polygonal blocks of lava. High stepping-stones, placed mostly at the corners, lead across from one trottoir to another, and these retain the impressions of horses' hoofs, while in the causeway between the wagons have left deep ruts. The street corners are provided with fountains, ornamented usually with the head of a god or a mask. Notices painted in red letters, and referring to municipal elections for which some particular candidate is recommended,



In Pompeii, from a Photograph.

occur frequently on the street walls, while trade-signs are few and far between. An occasional 'phallus,' to avert the evil eye, projects from over a doorway, and, much more common, one or two large snakes, emblems of the Lares, are to be seen. The stuccoed walls, to judge from the *Graffiti* (q.v.) or roughly-scratched drawings on them, were as tempting to the Pompeian *gamin* as to our own. House-construction consists mainly of concrete (rubble held together by cement) or brick, and sometimes of stone blocks, especially at the corners. Two-storied, sometimes three-storied houses are numerous, though the upper floors, built of wood, have been consumed by the eruption. Shops usually occupied the ground floors of dwelling-houses, on their street aspect, let out to merchants or dealers as at the present day, but not connected with the back part of the house. They could be separated from the street by large wooden doors, while inside they had tables covered with marble, in which earthen vessels for wine or oil were inserted. The shopkeeper had sometimes a second room at the back, when he did not live on an upper floor or in another part of the town. Retail traffic must have been considerable at Pompeii, to judge from the number of those shops along the streets, which, when not so flanked, presented bare walls, occasionally enlivened with a painting. Only a personal visit can convey an idea of the indoor life of the Pompeians, with whom the absence of glass, the fewness of the openings in the street aspect of the house-wall, and the protection of these with iron gratings are among the points noted by the most casual visitor. Models of the interior of an entire house in its original form are given in the fuller guide-books to Pompeii—the feature that most strikes the northerner being the smallness of the rooms, particularly the dormitories—quite intelligible, however, when he realises that the Pompeians led an open-air life, and performed their toilets at the bath, public or private. As rebuilt after 63, Pompeii shows little marble, the columns being of tufa or brick cemented by mortar. A coating of stucco was laid over wall or column, and presented an ample field for ornamental painting. This must have given to Pompeii its bright, gay colouring, which, with its reds, blues, and yellows, on column and capital, on wall and partition, harmonise so well with the glowing sunlight of the south. On the centre of the interior walls is generally seen a painting unconnected with the others—often of a nymph, or a genius, when not distinctly erotic in theme—typifying faithfully the voluptuous sensual life of this pleasure-haunt of paganism.

Thanks to photographs, and to plans and models in the best guide-books, the reader can inspect the excavated portion of Pompeii, and study minute and trustworthy descriptions of the temples, basilicas, public buildings, and private houses. Among the best substitutes for a personal visit are E. Neville Rolfe's *Pompeii, Past and Present*, illustrated by photographs of the ruins as they are, with sketches of their original elevations (Lond. 1884), and the copious and richly-illustrated books on the life and art of the city by August Mau and Pierre Gusman (both translated in 1900). The student who wishes to enter fully into the whole subject should read Mazois, *Les Ruines de Pompeii* (4 vols. Paris, 1812–38); Nissen, *Pompeian. Studien zur Städtekunde des Alterthums* (Leip. 1877); Mau, *Geschichte der dekorativen Wandmalerei in Pompeii* (Berl. 1882); Overbeck-Mau, *Pompeii* (Leip. 1884); K. Lange, *Haus und Halle* (Leip. 1885); while Professor Fiorelli's great work, *Gli Scavi di Pompei dal 1861 al 1872*, is a mine of information, supplied at first hand by the official excavator, and besides other matter contains an account of the ingenious method by which, pouring in liquid plaster of Paris into the hollows occupied by the skeletons of the victims of the eruption, and allowing it to harden, he obtained a 'perfect cast, consisting of the bones of the deceased Roman citizen, clad no longer in flesh, but in plaster of Paris.

Pompelmoose, or POMELO (Fr. *Pampelmouse*), also 'pumelon' and 'pomelo,' names for a kind of Shaddock (q.v.), all corrupted from the specific name *Pomum melo*.

Pompey. Cneius Pompeius Magnus, the rival of Cæsar, was born in 106 B.C., and at seventeen fought along with his father in the Social or Italian war on the side of Sulla against the faction of Marius and Cinna. When Sulla returned from Greece to Italy to oppose Marius (84) Pompey hastened into Picenum, and there raised an army of three legions, with which he drove the soldiers of Marius out of the district, and then joined Sulla. For his prudence, valour, and good fortune throughout the war he was sent to destroy the remains of the Marian faction in Africa and Sicily. On his triumphant return to Rome he was honoured with the name of Magnus, or the Great. His triumph was an unprecedented distinction for one who had not yet held any public office and was merely an *eques*. His next exploits were the reduction of the followers of Lepidus, whom he drove out of Italy, and the extinction of the Marian party in Spain under the brave Sertorius (76–71). Pompey suffered some severe defeats from Sertorius, and, indeed, put an end to the war only after his antagonist's assassination. Returning to Italy, he fell in with the remnants of the army of Spartacus, and thus closed the Servile war. He was now the idol of the people, and, though legally ineligible for the consulship, was elected for the year 70, the senate relieving him of his disabilities rather than provoke him to extremities. Hitherto Pompey had belonged to the aristocratic party, but of late years he had been looked upon with suspicion by some of the leading men, and he now publicly espoused the people's cause. He carried a law restoring the tribunician power to the people; and aided largely in introducing the *Lex Aurelia*, by which the *judices* should for the future be taken from the *senate*, the *equites*, and the *tribuni ærarii*, instead of from the senate alone. In 67–66 Pompey cleared the Mediterranean of the pirates who infested it; and during the next four years (65–62) conquered Mithridates, king of Pontus, Tigranes, king of Armenia, and Antiochus, king of Syria. At the same time he subdued the Jews and captured Jerusalem. On his return to Italy he disbanded his army, and entered Rome in triumph for the third time in 61. But now his star began to wane. Henceforward we find him distrusted by the aristocracy, and second to Cæsar in popular favour. After his return he was anxious that his acts in Asia should be ratified by the senate, and certain lands apportioned among his veterans. But the senate declined to accede to his wish, and he therefore formed a close intimacy with Cæsar, and the pair, together with the plutocrat Crassus, formed that coalition which is commonly called 'the First Triumvirate,' and which for a time frustrated all the efforts of the aristocratic party. This small oligarchy carried all before them: Pompey's acts in Asia were ratified, and his promises to his troops fulfilled; Cæsar's designs were all gained, and his agrarian law, distributing land in Campania among the poorer citizens, was passed. Cæsar's daughter, Julia, was given in marriage to Pompey, and private relationship was thus made to bind tighter the tie of political interest. In the year following Cæsar repaired to Gaul, and there for nine years carried on a career of conquest that covered him with glory, while Pompey was idly wasting his time and his energies at Rome. But Pompey could not bear a rival. Jealousies arose betwixt the two; Julia died in 54, and thus father-in-law and son-in-law were

sundered by a yet wider gulf, which no bridge could span. Pompey now returned to the aristocratic party, whose great desire was to check Cæsar's views, and strip him of his command. Cæsar was ordered to lay down his office and return to Rome, which he consented to do, provided Pompey, who had an army near Rome, would do the same. The senate insisted on an unconditional resignation, and ordered him to disband his army by a certain day, otherwise he would be declared a public enemy. To this resolution two of the tribunes in vain objected; they therefore left the city and cast themselves on Cæsar for protection. It was on this memorable occasion that he crossed the Rubicon, and thus defied the senate and its armies, which were under Pompey's command. The events of the civil war which followed have already been recorded in the life of Cæsar. It remains only to mention that, after being finally defeated at Pharsalia in 48, Pompey escaped to Egypt, where, according to the order of the king's ministers, he was treacherously murdered by a former centurion of his own, as he was landing from the boat. His head was cut off, and afterwards presented to Cæsar on his arrival in Egypt. But Cæsar was too magnanimous to delight in such a sight, and the murderer of Pompey was by his orders put to death. The body lay on the beach for some time, but was at length buried by a freedman, Philippus, who had accompanied his master to the shore.

Pompey's younger son, Sextus, by his third wife, endeavoured after his father's death to prolong the struggle with Cæsar. He secured a large fleet, manned largely by slaves and political exiles, and, occupying Sicily, ravaged the coasts of Italy. But in 36 B.C. he was defeated at sea by Agrippa, and next year was slain at Mitylene.

Pompey's Pillar, a celebrated column standing in the neighbourhood of Alexandria, on an eminence about 1800 feet south of the walls. It is a monolith of red granite, and of the Corinthian order, and stands upon a pedestal. Its total height is 98 feet 9 inches; shaft, 73 feet; 29 feet 8 inches in circumference. On the summit is a circular depression for the base of a statue. The name popularly applied to it is an erroneous appellation given by old travellers; the Greek inscription on the base shows that it was erected by Publius, prefect of Egypt, in honour of the Emperor Diocletian, 'the invincible;' and it is supposed to record the conquest of Alexandria by Diocletian, 296 A.D.

Ponani, a seaport town of British India, in the district of Malabar, 30 miles S. of Calicut. Pop. 12,241, mostly Mohammedans.

Ponapé. See CAROLINE ISLANDS.

Ponce de Leon. FRAY LUIS, a celebrated Spanish poet, was born in 1527, probably at Granada. He studied at Salamanca, entered the order of St Augustine, and became professor of Theology there in 1561. His translation and interpretation of the Song of Solomon brought him five years' imprisonment from the tribunal of the Inquisition at Valladolid. Released at length and reinstated in his chair, he quietly resumed his lectures with the words: 'As we observed in our last discourse.' In 1580 he published a satisfactorily orthodox Latin commentary on the Song of Solomon, later his *De los Nombros de Christo* (1583–85) and *La Perfecta Casada* (1583), full of imagery, eloquence, and enthusiasm, and both in prose. Shortly before his death, which occurred in August 1591, he had been appointed general of his order. His poetical remains were first published by Quevedo at Madrid in 1631, under the title *Obras Proprias y Traduciones.* The latter consist of translations from Virgil's *Eclogues* and the *Georgics,* the *Odes* of Horace, and the Psalms. His original poems are few, but they are among the masterpieces of Spanish lyrical poetry.

There are German monographs by Wilkens (1866) and Reusch (1873); also a Spanish Life by Tejede (1863).

Ponce de Leon, JUAN, the discoverer of Florida, was born at San Servas, in Spain, in 1460, was a court page, served against the Moors, and in 1502 sailed with Ovando to Hispaniola, and became governor of the eastern part of the island. In 1510 he obtained the government of Porto Rico, and had conquered the whole island by 1512, when he was deprived of his post. He then, broken in health, set out on a quest for the fountain of perpetual youth, and on 27th March 1512 found Florida, landing a little to the north of where St Augustine now stands. He secured the appointment of adelantado of the country, and, after staying on his way back to drive the Caribs out of Porto Rico, he returned in 1521 to conquer his new subjects; in this, however, he failed, and lost nearly all his followers. He retired to Cuba, and died there in July from the wound of a poisoned arrow. His remains and a monument are in San Juan de Porto Rico.

Poncho, an important article of male attire in Chili, the Argentine Republic, and some other parts of South America (see GAUCHOS). It consists of a piece of woollen or alpaca cloth, 5 to 7 feet long, 3 to 4 feet broad, having in the middle a slit through which the wearer passes his head, so that the poncho rests upon the shoulders and hangs down before and behind.

Pond. See WATER-SUPPLY.

Pond, JOHN, astronomer-royal, was born in London in 1767, studied at Cambridge, and succeeded Maskelyne as astronomer-royal in 1811. His name is identified with numerous improvements in the methods and instruments of observation; he translated Laplace's *Systeme,* and published a star catalogue and many valuable papers. He died 7th September 1836.

Pondicherry, the chief of the French settlements in India, situated on the Coromandel Coast, 53 miles S. by W. of Madras City, is divided into two parts by a canal, White (European) town being next the sea. It has handsome streets, a government house, a college, a lighthouse, and a cotton-mill employing 1500 hands, besides native dyeing establishments. Pop. 41,858. It exports chiefly oil-seeds. The French colony of Pondicherry has an area of 115 sq. m. and a pop. of 140,945. The governor of Pondicherry is governor-general of the French possessions in India. The French first settled here in 1674. The Dutch took the town in 1693, but restored it to the French in 1697. In 1748 Admiral Boscawen besieged Pondicherry for two months, but was compelled to raise the siege. Eyre Coote, however, took it in 1761, yet it was restored to the French in 1763 with reduced territory. It was once more taken by the English under Sir Hector Monro in 1778, and once more given back in 1783. In 1793 the English again repossessed themselves of it, but it was a third time restored to the French in 1816.

Pondoland, a district of Kaffraria, on the Natal frontier, South Africa, 65 miles long by 30 wide, was mostly annexed to Cape Colony in 1884 and 1887. East Pondoland was incorporated in 1894. Pop. about 200,000.

Pond-weed. See AQUATIC PLANTS.

Pongwe. See PUNGWE.

Poniatowski, a princely family of Poland. STANISLAS (1677–1762) joined Charles XII. of Sweden in supporting Stanislas Leszczynski, and was the chief instrument in saving the Swedish king at Pultowa. He held his administrative

offices under Augustus II. and Augustus III.—His son Stanislas Augustus (1732–98) was the last king of Poland (q.v.).—Joseph Antony, son of Andrew, brother of king Stanislas Augustus, was commander of the Polish legion in the army of Napoleon. He was born at Warsaw, 7th May 1762, and trained in the Austrian army. In 1789 the Polish Assembly appointed him commander-in-chief of the army of the south, with which he gained brilliant victories over the Russian invaders (1792); but the convention of Targowice (see Poland) put an end to the contest in 1793. On the outbreak of the following year he joined the army as a volunteer, but Kosciusko put him in command of the division charged to defend Warsaw on the north. On its fall he withdrew to Vienna. In 1806 the Prussians evacuated Warsaw before the invasion of the French; and when the duchy of Warsaw was constituted (1807) Poniatowski was appointed minister of war and commander-in-chief for the duchy. In 1809, in the course of the war between Austria and France, he invaded Galicia, after having previously retired before stronger forces. Three years later he joined, with a large body of Poles, the French army in its invasion of Russia, and rendered distinguished service at Smolensk and Borodino, but more especially in the great battle of Leipzig (1813), when he valiantly held his ground on the right wing of the French battle-array. Napoleon rewarded him by making him marshal of France. After the battle he was left to cover the retreat of the French army, and, whilst attempting to swim his horse over the river Elster to join the main body of his troops, he perished in its waters, 19th October 1813. His body was recovered, taken to Warsaw, and in 1816 removed to Cracow, and placed beside the ashes of Sobieski and Kosciusko. See (German) Biography by Boguslawski (Cracow, 1831).

Pont, Timothy (*c.* 1560–*c.* 1630), a pioneer in Scottish geography and map-making, was the son of Robert Pont (1524–1606), a celebrated Edinburgh minister. He graduated at St Andrews in 1584, was minister of Dunnet in Caithness (1601–8), and in 1609 subscribed for 2000 acres of forfeited lands in Ulster. 'He was,' says Bishop Nicholson, 'by nature and education a complete mathematician, and the first projector of a Scotch atlas. To that great purpose he personally surveyed all the several counties and isles of the kingdom; took draughts of 'em upon the spot, and added such cursory observations on the monuments of antiquity and other curiosities as were proper for the furnishing out of future descriptions. He was unhappily surpris'd by death;' but his collections were rescued from destruction and oblivion by Sir John Scott of Scotstarvet, and his maps at last appeared in Blaeu's magnificent *Theatrum Orbis Terrarum* (vol. v. Amst. 1654). See Dobie's *Cunninghame Topographised by Timothy Pont* (1876).

Pontac, an old name for a kind of red Bordeaux wine, from a family owning large vineyards.

Pont-à-Mousson, a town of France (dept. Meurthe-et-Moselle), on the Moselle, 18 miles SSE. of Metz, with a 13th-c. Gothic church. Pop. 11,261.

Pontarlier, a French town (dept. Doubs), 35 miles SE. of Besançon, on the main Jura route from Switzerland to France. Pop. 6709.

Pontchartrain, Lake, in Louisiana, about 5 miles N. of New Orleans, is 40 miles long and 25 wide, and communicates with the Gulf of Mexico. The drainage of New Orleans (q.v.) is carried into the lake through canals.

Pontecorvo, a city of the Italian province of Caserta, on the river Garigliano, 37 miles NW. of Capua, with 5172 inhabitants. It has an old cathedral and a castle. It was long attached to the States of the Church. Napoleon I. gave the title of Prince of Pontecorvo to Marshal Bernadotte, afterwards king of Sweden.

Ponta Delgada, the largest town of the Azores (q.v.), on the south coast of São Miguel. Pop. 17,940.

Pontefract, or Pomfret, a pleasant market-town in the West Riding of Yorkshire, on an eminence near the influx of the Calder to the Aire, 13 miles SE. of Leeds, 8 E. by N. of Wakefield, and 14 NNW. of Doncaster. It stands on the line of a Roman road, but seems to have arisen round its Norman castle, which, founded about 1076 by Ilbert de Lacy, was the scene of the execution or murder of the Earl of Lancaster (1322), Richard II. (1400), and Earl Rivers (1483), was taken in the Pilgrimage of Grace (1536), and during the Great Rebellion sustained four sieges, being finally dismantled in 1649, after its capture by Lambert. There are two old churches, a town-hall (rebuilt 1796), a market-hall (1860), a grammar-school of Edward VI. (1549), and large market-gardens and nurseries, the growing of liquorice for the lozenges called 'Pomfret cakes' being a specialty as old as about 1562. At Ackworth, 3 miles south, is a large Quaker school (1778). Pontefract, called *Taddenesscylf* in pre-Conquest times, seems to have received its present name between 1086 and 1135. Why is uncertain, but there is a very full discussion of this difficult question in *Notes and Queries* for 1886–87. The borough, which was chartered by Richard III., lost one of its two members in 1885. Pop. of parliamentary borough (1851), 11,515; (1881) 14,767; (1891) 16,407, of whom 9702 were within the municipal boundary.

See works by Paulden (1702), Tetlow (1769), and Boothroyd (1807).

Pontevedra, a cathedral town of Spain, in Galicia, at the head of a bay, 30 miles S. of Santiago. Cloth and hats are manufactured, and there are sardine-fisheries. Pop. 19,857.—The *province* has an area of 1695 sq. m. and a pop. (1887) of 443,385.

Pontiac, capital of Oakland county, Michigan, on Clinton River, surrounded by many small and beautiful lakes, 26 miles by rail NNW. of Detroit. It contains a state reform school and a large asylum for the insane, which cost nearly $500,000, and has flour and planing mills, foundries, and brickyards. Pop. (1890) 6243.

Pontiac, chief of the Ottawa Indians, in 1746 defended Detroit for the French, and was said to have led his warriors at Braddock's defeat in 1755. After the French had surrendered Canada, his hatred of the English prompted him to organise a conspiracy among the Indian tribes with a view to the extermination of 'those dogs dressed in red.' The 7th of May 1763 was appointed for the attack, which in eight cases was successful, and the garrisons were massacred; but at Detroit, where Pontiac led in person, the commander was forewarned, and a five months' siege ensued. Peace was made in 1766. Pontiac himself was murdered in 1769 by a Kaskaskia Indian, at Cahokia, Illinois, opposite St Louis. See Parkman, *The Conspiracy of Pontiac* (1851); and a *Diary of the Siege of Detroit*, ed. by F. B. Hough (1860).

Pontianak, capital of the western division of Dutch Borneo, near the mouth of the river Kapuas, on the west side of the island. It has some fortifications, and a lively trade. Pop. 5000.

Pontifex, the title borne by the members of one of the two great colleges among the ancient Romans, instituted for the purpose of preserving

and cultivating religious knowledge; the other was the college of Augurs. The name seems obviously to be derived from *pons*, 'bridge,' and the root of *facio*, 'I make;' but in what way the pontifices were connected with bridge-making is obscure. It is natural to suggest that it was in some way through the sacred bridge across the Tiber, the *pons sublicius*. It is customary to speak of the college of pontiffs as a 'priesthood;' it was not, however, strictly speaking, such—that is to say, the members were not charged with the worship of any particular divinity, nor did they conduct sacrifices. Their duties embraced the regulation of all the religious rites and ceremonies of a state—how the gods should be worshipped, how burials should be conducted, how the manes of the dead should be appeased. To them was entrusted the care of the calendar, the proclamation of festival days, &c. They also saw that every religious and every judicial act took place on the right day. 'As they had thus,' says Mommsen, 'an especial supervision of all religious observances, it was to them in case of need (as on occasion of marriage, testament, or *arrogatio*) that the preliminary question was addressed, whether the matter proposed did not, in any respect, offend against divine law.' In matters of religion they were the supreme authorities; from their decisions there was no appeal, and they themselves were responsible neither to the senate nor the people; further, they had power to inflict punishment on such priests as dared to disobey their injunctions and deviate into schismatical courses. The words of Festus are: *rerum quæ ad sacra et religiones pertinent*, JUDICES ET VINDICES. Their president was termed *pontifex maximus*.

The pontiffs, according to Roman tradition, were instituted by Numa, but as they appear in all the Latin communities they are regarded by Mommsen as a thoroughly national Italian institution, and probably found a place in the earliest religious organisation of the Latin race. Their number was originally four, or, including the *pontifex maximus*, five, all of whom were taken from the patricians. In 300 B.C. the Ogulnian Law raised the number to nine, four of whom were to be plebeians. The first plebeian, however, who attained the dignity of *pontifex maximus* was Tib. Coruncanius, 254 B.C. Sulla, in 81 B.C., again increased the number to fifteen, and Julius Cæsar to sixteen. During the empire the functions of *pontifex maximus* were generally discharged by the emperors themselves; and the name survived even the establishment of Christianity, occurring in inscriptions of Valentinian, Valens, and Gratianus; but at length the emperors dropped it, when it was assumed by the Christian bishops of Rome, and now this title forms one of the designations of the pope.

Pontifical, one of the service-books of the Church of Rome, in which are contained the several services, whether in the administration of sacraments or the performance of public worship, in which the bishop or a priest delegated by the bishop officiates. There were many such collections for the various national churches; but that which is now in universal use throughout the Western Church is the *Pontificale Romanum*, or Roman Pontifical, first printed in 1485, revised under Clement VIII. in 1596, and repeatedly republished since that time. The Pontifical contains the services for ordinations, for religious professions and receptions of monks and nuns, consecrations, benedictions, as well as of the solemn administration by a bishop of those sacraments which are ordinarily administered by priests. Besides the prayers to be recited, the Pontifical also lays down the ceremonial to be observed.

Pontigny, a village of the French department of Yonne, 18 miles SE. of Auxerre, with a famous Cistercian monastery, dating from the 12th century. Three English archbishops retired hither—Becket in 1164, Cardinal Langton in 1207, and St Edmund of Canterbury in 1240, the last being buried here. The monastery was devastated by the Huguenots in 1567, and finally destroyed at the Revolution; but the church (mainly 1150–70) is the most perfect Cistercian church in existence. To the shrine of St Edmund (18th century) in this church came in 1874 a pilgrimage of English Roman Catholics.

Pontine Marshes (Lat. *Pomptinæ Paludes*), a low-lying district, the southern part of the Campagna of Rome, extending south-east from Velletri to the sea at Terracina, 26 miles long by 17 broad. The district is separated from the sea by sand-dunes, and is traversed by the Appian Way. Herds of cattle, horses, and buffaloes feed on its pasture. Many attempts have been made to drain these marshes, from that of Appius Claudius (312 B.C.) to the proposals of Captain von Donat (1887), amongst the promoters of these drainage schemes being Augustus, Trajan, and the popes Boniface VIII., Martin V., Sixtus V., and Pius VI.

Pontoon (Fr. *ponton;* Lat. *pons*, 'a bridge'), the name given to buoyant vessels used in military operations for supporting a temporary bridge. Marlborough used clumsy wooden pontoons. Napoleon and Wellington had them lighter of tin and copper. They were flat-bottomed, rectangular boats, open at the top. Tin cylinders were then used for some time, but light open boats are now carried by the pontoon troops of the Royal Engineers for large bridges capable of carrying artillery, and Berthon's collapsible boats are sometimes used for small infantry bridges. See BRIDGE, Vol. II. p. 447; and for pontoons in connection with floating-docks, see DOCKS, Vol. IV. p. 32.

Pontoppidan, ERIK, Danish writer, born at Aarhus on 24th August 1698, was appointed professor of Theology at Copenhagen in 1738 and bishop of Bergen in Norway in 1747; there he died on 20th December 1764. His writings are principally historical and theological; amongst them must be mentioned *Annales Ecclesiæ Danicæ Diplomaticæ* (4 vols. 1741–52), written in German, and still of use as a book of reference; *Det Danske Atlas* (1781), an unfinished historical and topographical account of Denmark; *Glossarium Norvagicum* (1749), a work on Norwegian dialect words; *Explanations to Luther's Catechism*, used as a text-book down to the present day; *Marmora Danica* (2 vols. 1739–41), a collection of Danish inscriptions; and *Norges Naturlige Historie* (2 vols. 1752–54.; Eng. trans. *Natural History of Norway*, 1755), containing accounts of the Kraken, the sea-serpent, and other marvels.

Pontresina, a tourist centre in the Swiss canton of Grisons, stands in the Upper Engadine, on the road connecting with the Bernina Pass, and is much frequented by Alpine climbers. Pop. 383.

Pontus, the name given by the ancient Greeks to a country in the north-east of Asia Minor, bordering on the Pontus Euxinus (whence its name), and extending from the river Halys in the west to the frontiers of Colchis and Armenia in the east. Its southern limits were the ranges of Anti-Taurus and Paryadres, so that it corresponded pretty nearly to the modern pashaliks of Trebizond and Sivas. The name seems to have come into use after the time of Alexander the Great. Previous to that Pontus was governed by a satrap for the empire of Persia. One of these satraps, Ariobarzanes, early in the 4th century B.C., laid the foundations of an independent sovereignty. He

was succeeded by a line of princes mostly called Mithridates, the greatest of whom was Mithridates VI. (q.v.), one of the most formidable enemies that Rome ever encountered in the east. On the overthrow of this potentate by Pompey (65 B.C.), Pontus was annexed to Bithynia. Subsequently, a Greek named Polemon was installed (36 B.C.) monarch of part of Pontus; but in the reign of Nero this too became (63 A.D.) a Roman province, and was called *Pontus Polemoniacus*. The principal towns of ancient Pontus were Amisus, Sinope, Cotyora, Cerasus, and Trapezus on the coast, and Amasia (the capital), Comana, and Cabira (Neocæsareia) inland.

Pontypool, a market-town of Monmouthshire, on the Afon Llwydd, 9 miles N. by W. of Newport. Its 17th-century japanned wares have long been a thing of the past, and iron and tinplate works, brewing, and coal-mining now furnish employment. Pop. (1851) 3708; (1881) 5244; (1891) 5842.

Pontypridd, a town of Glamorgan, 12 miles NW. of Cardiff by rail, at the junction of the Rhondda and the Taff. It has a famous bridge (see BRIDGE), iron and coal mines, iron and brass foundries, and chemical and other manufactures—to which is due its rapid growth from a mere village at the beginning of the 19th century. Pop. (1881) 12,317; (1891) 19,971.

Pony. See HORSE.

Pood. See PUD.

Poodle. The origin of this breed of dog dates from the beginning of the 17th century or earlier, as many pictures of that time contain portraits of poodles. The breed was unknown in Britain until the beginning of the 19th century. The poodle is one of the few breeds of dogs which has not been properly appreciated and cultivated in Britain. From his great intelligence and cleverness in learning tricks, he was generally adopted as a circus or 'trick-dog;' but this fact, instead of making for his credit, has caused the poodle to be treated with contempt. On the Continent, however, the large variety of poodle has been universally used as the humbler sportsman's companion, as he combines the properties of a land as well as a water dog.

Black Corded Poodle.
(From a Photograph by Gambier Bolton, F.Z.S.)

The poodle varies considerably in his appearance, and attempts have been made to divide the breed into several sections, such as the large and small variety, or the corded-coated and fleecy-coated variety, as also into black Russian and white German poodles; but none of these divisions are very clearly defined. The large black Russian poodle is much the most handsome and agile specimen of the race, and may be easily trained to retrieve. The small white poodle is only fit for a house dog, but is extremely clever and apt. For some unknown reason the poodle has always been clipped in a peculiar manner: with the exception of a few tufts, his body and hindquarters are entirely bare, while the coat on his shoulders sometimes grows to an enormous length. On the Continent the poodle is left with his natural coat during the winter, a much more humane plan than the English habit of keeping him shaved in all seasons.

Pool, a game played on a billiard-table. Any number may play. Each is provided with a coloured ball, taken at random from a *pool-basket*. The first in order (white) is spotted on the *billiard spot*. The next (red) plays from hand on the white. Red is called white's *player*. The next (yellow) is red's player, and so on, in the order indicated by the *marking-board*. The owner of each ball has three *lives*. If the player holes the ball he plays on, or any other ball, after having first hit the ball he plays on, the owner of the ball holed loses a life, and has to pay to the player a sum previously agreed on. The player plays again, from where he stopped, on the nearest ball; and so on until he fails, when the next player goes on, or until there are no other balls on the table, when the striker's ball is spotted. After the stroke from hand the player, unless spotted, always plays from where he is on the table; when he is holed he plays his next stroke from hand. If the player holes his own ball or gives a miss he loses a life, and plays his next stroke from hand. When the owner of a ball has lost all his lives he is *dead*, and plays no more that pool. The first dead may *star*—i.e. may come in again with the smallest number of lives on the board. In the end one or two of the players, who have not lost all their lives, remain in. They continue to play until they have an equal number of lives, when they *divide* the pool (a sum contributed by each player, generally equal to the value of three lives, the star paying an extra pool). If one of the two who remain in has more lives than the other, and kills his adversary, he takes the *whole pool*. The above describes briefly what is called *following pool*. The principal varieties are *selling pool*, where the player may play on any ball he likes; and *black pool*, where an extra ball is spotted on the centre spot and has to be played on under certain conditions, about which there are no fixed rules. When the black is holed at black pool each of those in has to pay a life; if missed or run in off the player has to pay a life all round. There is no pool, and no one has any specified number of lives, the game continuing for a given time (generally half an hour). *Snooker pool* is played in the same way as *snooker* (see PYRAMIDS), the players following each other as at pool, and the order of play being determined as at pool.

Poole, a seaport of Dorsetshire, 5 miles W. of Bournemouth and 30 E. of Dorchester. It stands on the north side of Poole Harbour (7 by 4¼ miles), an irregular inlet, formed by the projection of the 'isle' of Purbeck, almost dry at low-water, and having four tides a day. On Brownsea or Branksea Island, just within the narrow entrance to the harbour, is a castle dating from the time of Henry VIII. Poole itself has an old town-hall (1572), a guildhall (1761), a town-house (1822), considerable shipping, some yacht-building, and a large trade in potter's and pipe clay. The men of Poole were great fighters in days of old by land and sea, as buccaneers, smugglers, and Cromwellian soldiery. There was 'Arripay,' or Harry Page, who about

1400 kept the seas against France and Spain; and there was William Thompson, who, with a man and a boy, captured a French privateer in 1695. Till 1867 the borough returned two members, and then till 1885 one. Pop. (1851) 9255; (1881) 12,310; (1891) 15,405. See works by Hutchins (1788), Sydenham (1839), and Brannon (3d ed. 1859).

Poole, John, playwright, born in 1792, died in February 1879 at Kentish Town, London, wrote the immortal *Paul Pry*, first produced at the Haymarket in 1825, and several other farces and comedies, such as *Turning the Tables*, *Deaf as a Post*, *'Twould Puzzle a Conjuror*, *The Wife's Stratagem*, &c. Besides these theatrical pieces he wrote also the satirical *Little Pedlington* (1839), *The Comic Sketch Book* (1859), *Comic Miscellany* (1845), *Christmas Festivities* (1845), and other books of a light, humorous kind.

Poole (or Pool; Latinised *Polus*), Matthew, divine, was born at York about 1624, educated at Emmanuel College, Cambridge, and held from 1648 till the passing of the Act of Uniformity (1662) the rectory of St Michael le Querne in London. He retired to Holland and died at Amsterdam in 1679. His principal work was his *Synopsis Criticorum Biblicorum* (5 vols. fol. 1669-76), in which the opinions of 150 biblical critics were summarised. In his *English Annotations on the Holy Bible* he had only reached Isaiah lviii., but the work was completed by his friends (2 vols. fol. 1685). Effective contributions to the Romish controversy were *The Nullity of the Romish Faith* (1666) and *Dialogues between a Popish Priest and an English Protestant* (1667).

Poole, William Frederick, the compiler of the 'Index,' was born at Salem, Massachusetts, 24th December 1821, and graduated at Yale in 1849. While there he was librarian of a literary society, and prepared an index (pp. 154) of periodical literature, of which a 2d ed. (pp. 521) was published in 1853, and a 3d (pp. 1469), with the assistance of the American and British Library Associations, in 1882. A supplement (pp. 496), by Poole and W. J. Fletcher, of Amherst, was issued in 1888; and a similar one was promised for every five years. From 1856 to 1869 he was librarian of the Boston Athenæum; afterwards he was employed in organising libraries (as at Waterbury and Cincinnati). From 1873 he had charge of the Public Library, and from 1888 of the Newberry Library at Chicago; and at Chicago he died in March 1894.

Poona, or Puna, a town of British India, 119 miles by rail SE. of Bombay, is the military capital of the Deccan and the seat of the government of the presidency during the last half of the year. The city is embosomed in gardens, but its streets are mostly narrow or crooked, and the houses poor. The ruins of the peshwa's palace, burned in 1827, still remain. Under the peshwas the city was the capital of the Mahratta princes and power; it was occupied and annexed by the British in 1818. Here have been built the Deccan College and the College of Science, the latter for training civil engineers, a normal school and normal college, a high school, and other educational establishments. The Europeans live chiefly at the cantonments, north-west of the city. The natives manufacture cottons and silks, gold and silver jewellery, ivory and grass ornaments, and clay figures. Pop. (1851) 73,209; (1872) 90,436; (1881) 99,622, to which must be added 30,129 in the cantonment; (1891) 160,460. The visitations of the sanitary authorities to native houses during the plague here in 1897 led to riots and murderous assaults.

Poon-wood is the timber of the Poon trees of India and Burma (*Calophyllum inophyllum* and *C. angustifolium*). It is very commonly used in the East Indies, particularly in shipbuilding, for planks and spars. See Tacamahac.

Poor Clares. See Clare (St).

Poor-laws. Charity, like Christianity, had its origin, or earliest development, in the East. Among the primitive nations of the world almsgiving was inculcated as a religious observance, and is prescribed as such in their sacred records. Among the European nations of antiquity we find a provision for the poor adopted as a matter of state policy. In early times Athens could boast of having no citizen in want; 'nor did any disgrace the nation by begging.' But war at length brought poverty in its train, and the Athenian people decreed the maintenance of those who were mutilated in battle, and, at a later period, of the children of those who fell. Plutarch mentions Pisistratus as the originator of the first decree, though others derive it from Solon. By the latter decree the state provided for the orphans of its soldiers up to their eighteenth year, and then sent them into the world with a new suit of armour. The bounty given to the disabled is mentioned by Lysias, Harpocration, Aristotle, Isocrates, and others; it is variously stated at one, two, and three oboli a day, and it seems to have been increased with the increased cost of subsistence. There were also societies for the relief of distress among the democratic states of Greece, called *eranoi*—a sort of friendly societies, in which the members relieved were expected to pay back the money advanced to them when they had raised themselves to better circumstances. But it must be remembered that these so-called democratic states were in reality slave-holding aristocracies.

Among the Romans the Agrarian Law of Licinius Stolo (367 B.C.) was framed in order to prevent the extremes of riches and poverty in the state. It limited the extent of property in public land to be held by each citizen, and directed that all such land above the allotted portion should be taken away from the holders, and given to those who had none. The distribution of grain at reduced prices, which at length became gratuitous, was introduced by Caius Gracchus, and lasted till the fall of the Roman empire. Augustus in vain tried to suppress it. In his time 200,000 citizens were thus fed. Cicero makes mention of this provision as in great favour with the Roman people, because it furnished them with an abundant subsistence without labour; other Roman writers describe its results as disastrous both to agriculture and to manners, creating a nation of mendicants, and causing the land to fall out of cultivation.

In the middle ages the great body of the labouring classes were in a state of serfdom, and looked to their feudal lords for maintenance. The obligation to provide for their slaves, or serfs, seems to have been fully recognised, so that many, encountering in a state of freedom the miseries of want, went back to bondage as a refuge from destitution. The villeins in Saxon England were attached to the soil, and received from their lord a portion of land for the support of themselves and their families. But the Church of Rome constituted herself the great receiver and dispenser of alms. The rich monasteries and abbeys distributed doles to the poor, as is still done at the mosques under the Mohammedan system.

In most states of continental Europe the church remains to a larger or smaller extent the public almoner, the state only stepping in to supplement the offerings of the church and voluntary charity when they become deficient. The disseverance from the church is hardly anywhere so complete as in England. The laws of different countries vary as to the degree of want entitling a pauper to

relief, the extent to which the right to relief is matter of positive right, the conditions which give rise to a claim of relief, the incidence of taxation, and the obligation on relatives to aliment.

It is only in Prussia, Denmark, and Sweden that there is any legislative declaration of the right to relief; and only in Britain and Denmark is any special tax imposed for this purpose. On the continent of Europe, generally speaking, the administration of relief falls on the parish or commune, but the responsibility of supervision undertaken by central departments varies greatly; no workhouse test is applied; and the statistics are not reliable. In northern Europe there has been a more decisive severance of poor-law functions from the church. In Denmark the old law was altered in 1867–68 to one of elective unions in rural districts, the burgomaster and town-council becoming the poor-law authority in each considerable town. The overseers are amateurs, and medical aid is universal. In Sweden the law formerly rested on the Church Ordinance of 1571, but the statutes of 1871 (translated by Nassau Jocelyn and criticised by Lammers) have made great changes, the relief of the able-bodied being prohibited, a direct liability being placed on the larger employers of labour, and a system of poll-taxation introduced. In Norway (where the system of out-quartering still subsists) the poor-law of 1845 was altered in 1863 in the direction of greater strictness, relief being restricted in theory to orphans and persons of unsound mind, and a maximum assessment fixed. Among other sources of income there is an excise duty on beer. In north Germany the old law of 1577 was gradually enlarged—e.g. by the Convention of Gotha and Agreement of Eisenach, dealing with the matter of settlement. In 1867 a law of free settlement was passed, and in 1870 by a general law the period of two years was fixed for pauper domicile. In Prussia this is further developed by a statute of 1871, which connects the *Bezirksregierung*, or local government, with the parish poor-law authority. The peculiar system of Leipzig (founded on that of Hamburg) is carried on by an *Armendirectorium*, amateurs of good social position, who make very strict inquiries by means of a *Fragebogen*, or question-paper.

In the Hanse towns there was introduced in 1788 a system of voluntary contributions aided by fixed subsidies from the government. This at length resulted in government supplying all deficiencies, which in the last few years have been 80 per cent. of the cost of the general poor relief. At the treaty of Versailles (1870) Bavaria preferred to remain under her own law of 1816, amended in 1869. In Belgium, known as the classic land of pauperism, there is no poor-rate, but large parochial endowments exist. As in France, there are *hospices civiles* for indoor relief, and *bureaux de bienfaisance* for outdoor relief. The law may be enforced on communes by the Deputation Permanente of each province. One-third of the Belgian proletariat are inscribed on the poor-lists (see Laurent, *Le Paupérisme et les Associations de Prévoyance*). In Russia the poor-law has been modified by the communal system of land-tenure and the large amount of unoccupied crown-land. Down to 1864 the landowner was bound to feed the serf, and there were also provincial charitable societies receiving state aid. The administration of the poor-law, however, was in that year handed over to the new *Zemstvos*, or local representative assemblies, who tax real property for this purpose. There is in St Petersburg a Grand Philanthropic Society with numerous branches; and many of the provincial offices of charity were endowed in the time of Catharine II. with the property of the monasteries. In Italy there is a remarkable absence of compulsory provision, except for lunatics and foundlings, but the charitable foundations amount to more than thirty millions sterling. The law of 1862, however, requires each charitable corporation to submit to the supervision of the representative provincial assembly. In Rome the *Commissione de Carita* has many peculiar features. Holland has no law of settlement.

In Austria each commune is charged with the relief of its poor. All who have legal domicile, or who, being unable to prove their domicile, are resident in the commune, are entitled to relief out of the general assessment. There is no special rate, and the administration is strictly municipal. In many provinces private charity is associated with public assistance, administered by the priest, a few chosen inhabitants, who are called 'Fathers of the Poor,' and an officer accountable to the commune. This system is called the 'Pfarrarmen Institute,' and their funds are principally derived from private sources; but they receive a third part of the property of ecclesiastics who die intestate, and certain fines, &c. The 'einlager system,' or boarding-out system, obtains to a large extent as regards both old and young paupers.

In France the law of 1798 distinctly negatived the right to relief. The present system rests mainly on the legislation of 1850–51, amended in 1872. The law of 1867 secured the intervention of the prefect. The relief of the poor is not compulsory, in as far as its distributors may, after making inquiry, refuse relief, except in the case of foundlings and lunatics. The minister of the Interior has a general superintendence of the machinery of relief, as well as the immediate administration of many large hospitals and refuges. The departmental funds are called upon for compulsory relief, but the commune is the main source of public assistance. It encourages and stimulates voluntary charities, and receives gifts for the benefit of the poor. The administration of the hospitals, and of the relief given at the homes of the poor (*secours à domicile*) is under the separate management of unpaid commissions, who co-operate with the communal authorities. The *dépôt de mendicité* is a penal establishment for the repression of vagrancy, and like the *crèche* is departmental. The work of the public dispensary is largely done by sisters of charity at a small salary and with unsatisfactory results, as at Boulogne.

In Holland pauper colonies have been supported by government for the last sixty years. Vagrants, after a short imprisonment, are sent to one of these, under a rigorous system of discipline. Paupers of good character are sent to maintain themselves and their families by agricultural labour in free colonies. The working of the system is pronounced costly and unsatisfactory. A description of the chief voluntary experiments in dealing with the poor in Europe will be found in *The Charities of Europe*, by John de Liefde (1865).

The annals of the poor in England are neither short nor simple. Severe enactments for the repression of vagabondage and mendicity date from a very early period. In ancient Saxon times the householder was bound to provide for the labourer, and men who had no master were, by the Folkmote, assigned to some householder; but when freedom began to prevail this state of things naturally came to an end. No master was bound to provide for the freeman, and when he failed to provide for himself, by honest labour, he generally took to vagrant begging, often to violence. The statute of Winchester (13th Ed. I., 1285) shows the poor utterly uncared for, and the roads infested by vagrant robbers. Up to the reign of Richard II. the sole idea of English rulers was to treat pauperism as a crime, and repress it by punishment, and by the

most unjust and absurd restrictions on the freedom of labour. The 23d Ed. III. forbids giving alms to vagrants, on pain of imprisonment; then also the laws of settlement had their origin in the attempt to chain the free labourer to the land. The 12th Richard II. (1388), chap. 7, is the first statute that makes provision for the impotent poor. The statutes of Henry VII. endeavour to carry out, by the severest measures, the system of repression. The 27th Henry VIII., chap. 25 (1536), introduced the principle of compulsory assistance. Each parish was ordered to receive and provide for the impotent, and set the able-bodied to work. Alms were to be collected into a general fund, and indiscriminate almsgiving was forbidden, on pain of forfeiture of ten times the value given. The sturdy beggar was to be whipped when first caught, next to have his ears cropped, and for a third offence to suffer death as a felon and enemy to the commonwealth. In 1547 the following penalties were substituted—viz. branding, on first conviction, with a V on the shoulder, and being adjudged a slave for two years, to be claimed by any one, fed on bread and water, and caused to work by beating, &c. Running away from this tender treatment was punishable with S branded on the face, and slavery for life to the town or parish, on the roads of which the incorrigible vagrant was to work in chains. A little urging was now found necessary to obtain funds for the maintenance of the poor. The collectors were gently to ask every man and woman at church what they would give; but if one could not be persuaded the bishop was to send for the recusant, and use 'charitable ways and means.' At length the 5th Elizabeth, chap. 3 (1563), provided that he who obstinately refused to give should be handed over to the justices, who were empowered to tax him at their discretion, and send him to jail for default. Ten years later the power of compulsory assessment is given to the justices, and abiding-places are ordered to be provided for the aged and infirm. These statutes culminated in the 43d Elizabeth, chap. 2 (1601), which has formed the basis of the poor-law system of England up to the present time. It taxed every inhabitant of every parish for the relief of the poor. It directed the justices in every county to appoint three or four substantial householders in each parish to be overseers of the poor, along with the churchwardens. It ordered the relief of the impotent, and the apprenticing of children, and the providing of work for the able by means of 'a convenient stock of flax, hemp, wool, thread, iron, and other necessary ware and stuff.'

The great Act of Elizabeth came but slowly into operation. Up to the reign of Charles I. there were many parishes in which no rate was assessed, and which turned away their poor; but the great evils had been remedied, and there is little legislation on the subject for the next hundred years. The 3d William and Mary, chap. 2 (1691), provides that the persons to be relieved be registered and examined by the vestry, because evils had arisen out of the unlimited power of the churchwardens and overseers giving relief 'for their own private ends,' by which the charge on the parish was greatly increased, contrary to the true intent of the statute of Elizabeth. This act also gave power to the justices to order relief in cases of emergency, a provision which afterwards became a fruitful source of difficulty. The evils henceforth complained of were that many had thrown themselves on the rates who ought to have been supporting themselves independently of such aid; that pauper labour was found interfering with and displacing industrial labour; that the overseers were acting with unchecked dishonesty; and justices, with unrestrained liberality, ordering the money of the industrious and prudent to be spent upon the idle and improvident. Efforts were made to remedy these abuses throughout the reigns of the first three Georges, by making the justices act with the overseers, by rendering the overseers accountable to the parishioners by means of returns and the power of inspection, and by the offer of the workhouse to all applicants for relief. This last provision, made in the reign of George I. (1723), substituted what is called indoor relief for the allowance made to the poor at their own homes, and introduced the workhouse system. The workhouse established on Locke's suggestion by Carey at Bristol was one of the earliest. All who refused to be lodged in the house were to be struck off the poor's-roll and refused relief. A great increase in the number of workhouses took place; guardians were appointed to guard the pauper children from neglect and improper conduct, and other attempts to improve their administration made. Workhouse Unions were also introduced by Gilbert's Act, 1782, and a succession of acts passed for the protection of parish apprentices. Towards the close of the 18th century a great relaxation took place in the treatment of the poor. The famous Speenhamland Act of 1793 meant the establishment by justices of a minimum rate of wages. The 36th Geo. III., chap. 10 and 23 (1796), increased the amount, and extended the application for relief. It repealed the workhouse test, and allowed relief to be given in aid of wages. Henceforth outdoor relief became the rule under a variety of systems, which practically turned the poor-laws into a mode of paying wages. In 1801 the amount of the rates was reckoned at £4,000,000. In 1820 it had risen to £7,330,254, the justices being now the 'rating' as well as the 'relieving' authority.

In 1817 a commission of the House of Commons stated their opinion, that, unless checked, the assessment would swallow up the profits of the land. Though the two Vestry Acts, which resulted from the commission appointed in 1817, seem to have done something to remedy the evils complained of, a new commission to inquire into the operation of the poor-laws was found necessary, and appointed in February 1832. The evidence brought before this commission, with which the names of Bishop Blomfield, Sturges-Bowme, Edwin Chadwick, and Nassau Senior are always connected, revealed a disastrous state of things. The independence, integrity, industry, and domestic virtue of the lower classes were in some places nearly extinct. The great source of the evil was shown to be the relief afforded to the able-bodied in aid of wages. This aid at first reduced the expenditure in wages, and found favour with farmers and magistrates, who framed scales of relief in accordance with the wants of the people. Five modes of outdoor relief were found in operation: (1) Relief without labour; (2) allowance given, in aid of wages, according to the number of the labourer's family; (3) the Roundsman system, the labourers being let out by the parish, among the employers round; (4) parish work, generally on the roads: (5) the labour-rate, the ratepayers preferring to divide among them the pauper labour, and to pay for it, however valueless, instead of raising a rate. Diminished industry ate away the very root of capital. Farmers turned off their men, or refused to employ them at fair wages, thereby causing a surplus of unemployed labour; they then took them back from the parish at reduced wages, paid out of the rates. From parish after parish came the reply to the queries of the commissioners: 'All our able-bodied labourers receive allowance.' No poor man in such parishes could save; if it was known that he had a fund of savings 'he would be refused work till the savings

were gone,' and he had come down to the pauper level. In many places pauperism swallowed up three-fourths of the rent. Nor was the mal-administration confined to the rural districts; it extended all over the country, and into the manufacturing towns, where outdoor relief was a source of constant imposture. The administration of in-door relief was also full of abuses, from want of classification, discipline, and employment. Better food and lodging were provided for idle paupers than working-people could procure—better, even, than could be afforded by many of the ratepayers.

In 1834 the commissioners reported that they found the administration 'opposed to the letter and spirit of the law, and destructive of the welfare of the community.' The commissioners laid down the principle that the condition of the pauper ought to be below the lowest condition of the independent labourer, because every penny bestowed in rendering his condition more eligible is a bounty on indolence and vice, and recommended (1) the cessation of outdoor relief; (2) a central authority to control the administration; (3) unions for the better management of workhouses, and the classification of their inmates; and (4) a complete and clear system of accounts. The bill embodying these recommendations was brought in, March 17, 1834, passed its second reading in the House of Commons with only twenty dissenting votes, and became law on the 14th August as the 4th and 5th Will. IV. chap. 76. This act was not a change of law, but of administration. The orders of the new board restricted overseers, on the formation of a union, to the collection of rates; appointed paid relieving-officers to dispense relief under the directions of the unpaid Boards of Guardians; required the gradual withdrawal of outdoor relief; and enforced classification and discipline in the workhouses. A rapid formation of unions took place under the new board. In the first eight months 112 were formed including 2066 parishes. The pauperised districts experienced a great and immediate relief, numbers of paupers going off when they found that relief involved adequate work or the strictly-disciplined workhouse; wages rose, and the expenditure was reduced on an average 20 per cent. At the accession of George I. in 1714 the poor-rates amounted, as nearly as can be estimated, to £950,000, equal to 3s. 3¾d. per head on the population of 5,750,000. At the accession of George III. in 1760 the population had increased to 7,000,000, the poor-rates to £1,250,000—an average of 3s. 6¾d.; while in 1834 the population, estimated from the last census, was 14,372,000, and the money expended in relief £6,317,255—equal to 8s. 9½d. per head. In three years the operation of the Amendment Act had reduced the expenditure one-third—viz. to £4,044,741. In 1848 the commissioners were exchanged for a public board, which became one of the government departments, with a president, in whom was vested the power of the commissioners, and who held office as one of the ministers of the crown. Finally, in 1871, the Poor-law Board was abolished, and its powers transferred (with various other powers) to a new body, the Local Government Board (q.v.), which accordingly became the central authority for England and Wales in regard to poor-law administration. The commissioners were unable to withdraw outdoor relief, which continues to be in England the most important item. With the aged, the sick, and orphans the guardians deal at their discretion; but stringent rules for the relief of the able-bodied are in operation under the board, whose orders have the force of laws. In the rural districts guardians are prohibited from giving relief to the able-bodied out of the house, unless under a supplemental order in emergency. For other places the general rule forbids relief to be given in aid of wages, and requires work to be supplied. Exceptions are made by the board on the application of the unions when necessity arises. The expenditure is strictly guarded and examined by public auditors. A district medical officer, of whom one or more are appointed for each union, attends to all cases of sickness among the poor.

The fundamental rule adopted as to the relief of the poor was that each parish in England and Wales is bound to maintain its own poor. Overseers are required to be appointed in each parish every year; and these (till 1894, along with the churchwardens, till then *ex officio* overseers) have to provide the requisite funds. This is done by means of a poor-rate, which the churchwardens and overseers may levy on all the occupiers of land in the parish, after such rate has been confirmed by the justices. The rate specifies a certain sum in the pound which is to be levied, and the annual value of the various lands is then specified. The rate is thus a local tax on the occupier of the land, and not on the owner, unless he himself is also occupier. Owing to the mischiefs arising from the officials of each parish distributing the funds at their discretion, without uniformity of plan, authority was given to combine various parishes into one poor-law union, and a central controlling power was created in 1834 in the shape of the Poor-law Board, now the Local Government Board. When a union is formed the control of the expenditure is chiefly vested in the guardians of this union, who are elected by each parish, and who supervise the management of the union workhouse. They order the overseers of each parish to raise their due proportion of funds by a contribution order issued to such overseers, who are thereon bound to levy the amount by including it in the next poor-rate. The guardians are bound to contract for the provisions, clothing, fuel, &c. supplied to the workhouse, by means of sealed tenders, unless the quantity is less than a stated amount. The guardians profess only to relieve destitution already existing, and not to enable persons to keep off impending destitution. Hence they only supply the bare necessaries of life. They cannot, for example, advance or lend money to set up a poor person in trade.

Minute regulations are contained in the consolidated poor-law orders of the Board as to the classification of paupers in the workhouse, mode of admission, diet, discipline, and outdoor relief. It is provided that every able-bodied person requiring relief from any parish shall be relieved wholly in the workhouse, together with his wife and family, if any, and if not otherwise employed. But the relief may be given out of doors in cases of sudden and urgent necessity, of sickness, accident, and a few other cases. In general relief is confined to persons actually residing in some place within the union, except in case of casual destitution, or sickness and accident. Whenever outdoor relief is given to an able-bodied person half of it is to be in the form of articles of food or fuel. Relief is given only weekly where the pauper is not required to be received into the workhouse. No relief is to be given to able-bodied persons while they are employed for wages or hire by any person; and every able-bodied male person, if relieved out of the workhouse, shall be set to work by the guardians, and kept so employed while he continues to receive such relief. Wherever a person applies for parochial relief, if he or she has a father or grandfather, mother or grandmother, or child, who is able to maintain such pauper, the parish officers can obtain an order from justices to compel such relative to contribute a sum towards such maintenance. In some cases the guardians or overseers may employ the poor in public works; but this is

seldom done except on occasions like the Lancashire distress. The law as to the settlement of the poor is somewhat intricate, and gives rise to much litigation. There are various grounds on which this settlement is acquired. Thus, every person has, *primâ facie*, a settlement in the parish where he was born, until some other is proved; and there are so many other qualifications that it is seldom a birth-settlement is resorted to. By marriage a woman immediately acquires the settlement of her husband, if he has one, whether the husband be an Englishman or a foreigner. If the husband has no settlement, then the wife is thrown back on her maiden settlement. If any person shall be bound an apprentice by indenture, and reside forty days under such apprenticeship, or has resided three years in a parish, or shall rent a tenement in a parish, and actually occupy the same, and be rated to the poor for one whole year, the rent being not less than £10, and paid by the person so actually occupying the tenement, or shall acquire an estate in land, however small in value, and reside forty days in the parish, or shall buy an estate, and the consideration amount to £30 at least, he shall by any of these methods acquire a settlement. Unless a pauper has acquired a settlement in the parish or union where he receives relief, he is liable to be removed compulsorily to the parish where he last acquired a settlement. Paupers who have resided for one whole year in the parish or union in which they became destitute cannot, however, be removed. The general expense of maintaining the poor is paid out of the common fund, and not by each parish in the union. When a pauper is sought to be removed it is necessary to take him before two justices of the peace for examination; and, on proper evidence of his settlement, the justices will make the order of removal, which is an authority to the overseers to take or send the pauper to the overseers of the parish of settlement. If, however, the pauper is too ill at the time to admit of removal without danger, the justices may suspend the order of removal till he is recovered. Whenever a pauper is to be removed the removing union is bound to give notice to the union of settlement; and it is on these occasions that so many obstinate and costly litigations take place as to which is the union of settlement. The union also may appeal to the court of quarter sessions against the removal order; and the quarter sessions may state a case for the opinion of the Court of Queen's Bench, if any nice point of law should arise, as frequently happens. This evil of litigation was greatly diminished by the Union Chargeability Act of 1865. The Local Government Act of 1894 left the administration of the poor-laws of England with the guardians and overseers. But churchwardens ceased to be *ex officio* overseers; the parochial electors appoint the guardians, and the parish council appoints the overseers, additional ones being appointed in place of the churchwardens.

Scotland and Ireland have been legislated for separately. Their poor-laws are similar to the English in principle and practice; both are administered by a central board, which supervises the local bodies charged with relief, and in both the rate is levied on the annual value of real property. In Scotland the usual early legislation was passed against sturdy beggars and vagabonds. A system of assessment by the owners in each landward (i.e. non-urban) parish was set up in 1579 and 1663, and the general policy of the poor-laws was stated in proclamations by the Privy-council in the end of the 17th century. Until the 19th century, however, the poor in most parishes were supported out of the voluntary collections at the parish church, administered by the heritors and kirk-session. In spite of the opposition of Dr Chalmers, a new system was instituted in 1845. Relief was administered by a parochial board, appointed by the ratepayers, the burgh magistrates, and the kirk-session; and the board appointed 'inspectors of the poor' as relieving-officers. The Scots law differs from the English and Irish in allowing no relief to able-bodied adults. Claimants must be aged, infirm, or disabled. Outdoor relief is the rule. In 1845 a central board was established, called the Board of Supervision, controlling the parochial board of each parish like the Local Government Board in England, though with less extended powers—thus, although parochial boards might combine to build workhouses, there are no unions, properly so called, in Scotland. A settlement can be acquired in Scotland by residence of five years. Children follow the settlement of their parents, and wives that of their husbands; and if no other settlement be proved, then the settlement of birth is liable. In Scotland the poor-rate, except in a few cases where the local usage established in 1845 is followed, is universally imposed equally upon owners and occupiers according to the annual value of the houses, works, farms, mines, &c., by which is meant the net annual value, after allowing for repairs, insurance, and other expenses, and not the gross annual value appearing in the valuation-roll. Each parochial board, however, may exercise an important power of classifying subjects according to the use to which they are put, and giving appropriate deductions from annual value. The tendency of this system is to approach an assessment imposed upon probable income, the older assessment in Scotland having frequently been laid on means and substance. The parochial boards, originally created solely for administering the poor-laws, were gradually utilised for carrying out the law as to burial-grounds, the registration of births, deaths, and marriages, vaccination, public health, and public libraries. The Local Government (Scotland) Act of 1894 (unlike the English act) transferred the powers and responsibilities of the parochial boards to the newly constituted Parish Councils; and in Scotland the administration of the poor-laws, especially of the great act of 1845, is the most important duty of the Parish Council. At the same time the Board of Supervision is abolished, and its powers transferred to the Local Government Board for Scotland, a semi-independent body being thus superseded by a state department (in Edinburgh, as before). The Secretary for Scotland is president of the board, which through him is responsible to parliament.

In Ireland the Poor-law Act was passed for the first time in 1838, and numerous amending statutes have followed, the code of laws being substantially founded on the English acts. Each union has a workhouse managed by a Board of Guardians elected by the ratepayers. Every destitute person has an absolute right to relief, which is administered almost entirely in the workhouse. The Local Government Act of 1898 made no essential changes. There are special acts of parliament regulating the conditions on which paupers are removable between England, Scotland, and Ireland respectively.

In recent times a new policy has been devised, and in the German empire carried into practical effect, of providing against the evils which the poor-law is intended to alleviate. This policy is generally known as that of compulsory insurance. The German law of 13th June 1883 on sickness insurance was followed by that of 6th July 1884 on accident insurance, and that of 22d June 1889 on insurance against permanent disability and old age. Compulsory contributions are collected, to which the workman, the employer, and the state are all parties. The disability pension is given after

five years' payment, the old age pension after thirty years' payment and after the age of sixty. Where the wages are below 350 marks the contribution is 14 pfennige per week. The disability pension starts from a minimum of 60 marks, to which the state adds 50 marks, the balance depending on the number of weekly contributions made. The old age pension is only 106·40 marks, or about £5, 10s. for the lowest class of salary. The grave difficulties of this scheme (which came into operation on 1st January 1891) are sufficiently obvious: (1) the workman has to keep a card-register all through life; (2) the employer has to submit to inspection, and to contribute a fixed sum for all wages under a certain figure; (3) the annual charge to the state is expected to exceed £4,000,000 sterling.

A comparison of the statistics of poor-law administration for England and Wales in 1872 and 1889 is interesting and encouraging. In 1872, the population (1871) of England and Wales being 22,712,266, there were 977,200 paupers, of whom 150,930 were able-bodied adults. The total cost of poor relief was £8,007,403, while the rateable value of property assessed was £107,398,242. In 1889, the population (1891) being 29,081,017, the corresponding figures were: paupers, 817,190, of whom 104,817 were able-bodied adults: cost, £8,232,472; property assessed, £139,636,307. The burden had diminished from 1s. 5½d. to 1s. 1½d. per £1 (see VAGRANTS).

In Scotland in 1890, the population (1891) being 4,025,647, the paupers were 92,324; the expenditure, including buildings, was £874,389, contributed to the extent of 76·8 by assessment, and grants in aid 17·6, being at the rate of 4s. 4d. per head of population, and 1s. 6d. lower than in England. The cost of the lunatic poor rapidly increases. In Ireland, the population in 1891 being 4,706,162, the average daily number, in 1890, of paupers in the workhouses was 43,536, and on outdoor relief 62,286, together 105,822. In 1889 the total expenditure on poor relief was £853,912. It would be misleading to draw inferences from these figures with respect to the condition of the respective countries, as the practical details of poor relief vary greatly.

In America the system is on the whole similar to the British. Every man is entitled by law to relief from the town of his settlement, the rate being assessed on whole towns, and not on parishes. The states have their own poor-laws, but paupers are removable from one state to another. Thus, in Massachusetts the unit of poor-law administration is the town or city, comprising in each case the surrounding rural district; while in New York the unit, generally speaking, is the county. These areas bear the burden of the settled poor; the unsettled poor (including Indians) are a charge upon the state. In New York one year's residence is sufficient to constitute a settlement. The policy in Massachusetts has been to encourage outdoor relief as being more economical, and for this reason to facilitate settlement. Any American becoming a pauper loses his state rights. The acts concerning Workhouses and Paupers in the Revised Code of Massachusetts may be taken to represent generally the state of the law throughout the Union. The former provides 'that any town may erect or provide a workhouse for the employment and support of all poor and indigent persons that are maintained by, or receive alms from, the town; all persons who, being able to work, and not having means to maintain themselves, refuse or neglect to work; all persons who live a dissolute vagrant life, and exercise no ordinary calling or lawful business; and all such persons as spend their time and property in public-houses, to the neglect of their proper business, or by otherwise misspending what they earn, to the impoverishment of themselves and their families, *are likely to become chargeable to the town or the commonwealth.*' The idle and the vagrant may be committed to the workhouse, and kept to labour, as in a house of correction. There are provisions for enforcing the claims of kindred and for the immediate relief of strangers. The administration is in the hands of overseers, but the counties elect superintendents, holding office for three years, who are again responsible to a Board of Supervisors. The New York State Board of Charities contracts with the counties for the housing in almshouses of certain classes of the state poor. The State Boards have large general powers of supervising the whole charitable, reformatory, and correctional system of the commonwealth, and report annually to the legislature on such questions. These boards are mainly nominated by the governor. Their functions and the results achieved are described in Mr Sanborn's Report to the Massachusetts Centennial Commission, 1st February 1876, and in the Report by Mr Henley to the Local Government Board in June 1877 (Parliamentary Papers, vol. xxxvii.), on the Poor-laws of certain of the United States, and on the combination there of private charity with official relief. The Massachusetts state workhouse and almshouse are at Bridgewater and Tewksbury respectively; the most important establishment in New York state is on Blackwell's Island. Generally the American system is marked by a high degree of classification, variety of work, special educational methods, and liberal treatment in the matter of diet. In the city of Boston, under special statutes, the authority of overseers is largely superseded by a 'Board of Directors for Public Institutions.' The former practice of levying a small poll-tax on poor immigrants was decided by the case of Henderson *v.* Wickham (1876) to be illegal. With reference to the efforts made by voluntary associations to assist and develop the working of the poor-law in America, Mr Henley reports that this cannot properly be done except under a well-considered regulation having the force of law, and a paid staff of officers acting under the orders of representative and responsible administrators, controlled by independent auditors.

There is no poor-law in the Australian colonies, but benevolent asylums for the infirm and destitute have become general, and hospitals are numerous in all the rising towns.

Poor's-roll, in the practice of the law of Scotland, means the list of poor persons who are litigants, but unable to pay the expenses of litigation, and therefore are allowed to sue *in formâ pauperis*. This privilege is only granted on production of a certificate by the minister of the parish and two elders, setting forth his circumstances to their own knowledge and his general poverty. Notice is given of this to the adverse party, who is allowed time to inquire and oppose the application. Where the applicant is not in Scotland he may make a declaration of poverty before a magistrate—e.g. in Ireland. When the court is satisfied of the poverty the next thing is for the court to remit the matter to the reporters appointed by the Faculty of Advocates, who report whether there is a *probabilis causa*—i.e. a plausible cause of action. If this report is made it is considered conclusive, and the party is put on the poor's-roll. This warrant remains in force for two years, and during that time the pauper is exempt from all fees of court, and has the gratuitous services of counsel and agents, whose names appear on a list made by the Faculty of Advocates and other legal bodies. This provision for enabling paupers to carry on litigation is unknown in England or Ireland; for though a party may also be allowed there to sue *in formâ pauperis*, no provision is made by the court for giving him the gratuitous services of counsel and attorney. There is also a list of poor's counsel in the High Court of Justiciary. By an old custom a panel charged with murder may claim the gratuitous services of the Dean of Faculty. See IN FORMÂ PAUPERIS.

Popayan, capital of the department of Cauca in Colombia, stands in a fertile plain, 5700 feet above sea-level, near the river Cauca. It is a bishop's see, although its cathedral is now in ruins; and it has a university and normal school, and manufactures woollens. Founded in 1537, it rose to considerable importance; but the civil wars and an earthquake in 1827 have done much to reduce it. It is still of some consequence for the trade with Peru. Pop. 9000.

Pope. See RUFFE.

Pope (Gr. *pappas*, Lat. *papa*, 'father;' at first used of all bishops, from the 5th century gradually appropriated in the West to the Bishop of Rome, though still used of priests of the Greek Church), the Bishop of Rome, and supreme pontiff of the Roman Catholic Church. In this article an historic sketch will be given of the papacy as an institution. While the empire remained pagan the history of the bishops of Rome is obscure. Tradition confirmed by the faith of the church represents St Peter as the first Bishop of Rome. His immediate successors must have been recognised by Christians as the heads of Christ's church in the imperial city. Rome, the mistress of the world, was regarded by all men with reverence; all men came thither. So among Christians its bishop held a position of special dignity, and his judgment in ecclesiastical controversies was regarded as weighty. The heresy of Novatian, irregularly ordained Bishop of Rome during the lifetime of Cornelius (251), illustrated the importance of ecclesiastical unity, and so in the end tended to exalt the Bishop of Rome as the visible head of the church.

Under Constantine the empire became Christian, and Rome ceased to be the sole imperial city. The first of these changes vastly increased the dignity of its bishop; the second separated Latin from Eastern Christendom; the heresies of the speculative East found no acceptance in the West; the Bishop of Rome became the champion of orthodoxy, and was recognised by the Council of Sardica (347) as having appellate jurisdiction. Before the end of the 4th century Siricius, in publishing his decretal on clerical celibacy, assumed that the law of the Roman Church was binding everywhere. A great increase in power may be dated from the reign of Innocent I. (402–417), who claimed, as the successor of St Peter, superiority over western Christendom. The weakness of the western empire, the sack of Rome by the Visigoths, and the reverence which they paid to all things Christian, combined to make Innocent the most powerful person in the Christian city which rose upon the ashes of pagan Rome. Leo I. (440–461) maintained the claim of his see to the patriarchate of the West, while in Rome and Italy his fearlessness and prudence during the invasions of the Huns and Vandals gave him commanding influence. In 476 the empire of the west came to an end; the sole emperor of the Romans reigned at Constantinople. As long as he left Italy alone the papal power was the stronger for his absence. Amid the political disintegration of the West the church remained a stable bond of union; its centre was Rome, and the head of Rome was the pope, who became more and more regarded as the leader and defender of the people. Though Theodoric the Ostrogoth, while master of Italy, abstained from interference with the bishops of Rome until shortly before his death, some trouble arose from disputed elections. The election anciently lay with the clergy and people of the city, but as the interference of the laity led to violence, Symmachus decreed (498) that thenceforward the election should be decided by the votes of the Roman clergy. The reconquest of Italy by the generals of Justinian impaired the papal power, for he treated the pope like a rebellious servant. As the imperial power waned in Italy before the invasion of the Lombards, the pope again became pre-eminent. Neglected by her emperor, Rome found a protector in Gregory the Great (590–604), who was forced by the sufferings of the people to deal with the Lombards as a temporal prince. Yet his work was chiefly spiritual. Under him the right to the patriarchate of the West was firmly established; his holiness, his writings, and his reforms were universally admired; he exercised ecclesiastical discipline over the bishops of other lands, and he resented the indignity put upon his see by the assumption of the title 'Universal Bishop' by the Patriarch of Constantinople. Under him the Arian invaders of Italy, the Lombards, were converted to Catholicism; so, too, were the Arian Visigoths of Spain; while the heathen English first received the gospel from missionaries whom he sent out. Gregory completed the work of Innocent and Leo, and was the greatest of the three founders of the papacy of the middle ages.

During the 7th century the popes were much troubled by the eastern emperors, who were still lords of Rome and some parts of Italy. The emperors caused elections to the papacy to be submitted to themselves for confirmation, tried to force the popes to concur in their heresy concerning the will of Christ, and treated them as mere officers of their state. Martin I. (649–654), a strenuous opponent of the Monothelite heresy, was seized, carried off to Constantinople, and, after suffering ill-usage, died in exile. Even when the emperors again became orthodox they still humiliated the popes. Meanwhile the papal power was growing in western lands: the English turned from Columban usages, and professed obedience to Rome (664); the Burgundians and Frieslanders received the gospel; and early in the 8th century Boniface won over a large part of Germany to the faith, acting on a commission from Gregory II. (715–731). In Gregory's time the Emperor Leo III. forbade the worship and even the use of images throughout his empire,

whence he and his successors who adopted the same policy are called Iconoclasts (image-breakers). Gregory refused to obey his decree, and was upheld by the Italians and the West generally. The imperial governor in Italy, called the exarch, sought to compel the pope to obey his master, and the Italians rose in the pope's defence. The Lombards took advantage of the confusion to conquer the exarchate. They threatened the lands of the church; no help was to be had from the emperor; Italy was virtually severed from the empire. In his distress, Gregory III. (731–741) appealed for help to the Catholic Franks. Twice Pepin brought an army of Franks to the pope's relief, and routed the Lombards; he won back from them all that had belonged to the exarchate in Northern Italy, and bestowed it on the Roman see (754). This was the beginning of the temporal power of the popes. In return Pepin accepted from the pope the title of Patrician of the Romans, an acknowledgment of his rights in Rome, and of his duty as the defender of the church. He had already received the papal sanction for the deposition of the Frankish king and his own coronation; the pope's action in this matter formed a precedent not forgotten by his successors. Pepin's son, Charles (Charlemagne), again routed the Lombards, and renewed his father's donation. At another visit he declared Leo III. (795–816) guiltless of certain crimes with which he was charged, and on Christmas Day, 800, Leo crowned him emperor. It was contrary to the feelings of the age that the church should lack an imperial protector; the breach with the eastern empire was complete, and the imperial throne at Constantinople was held to be occupied unlawfully. While Leo had allowed his cause to be judged by a temporal prince, and had accepted him as master of Rome and emperor, he had assumed as God's vicar the right to bestow the imperial crown, which carried with it the lordship of the world.

During the struggles that preceded the break-up of the Frankish empire the popes generally favoured the princes of the West (or Gaulish) Franks, rather than of the East (or German) Franks. The rise of separate nations threw political power into the hands of the great churchmen of the new states. The pontificate of Nicolas I. (858–867) was marked by the successful assertion of the authority of Rome in correcting the vices of princes, and compelling the submission of the most powerful prelates of the West, such as the Archbishop of Ravenna, certain German bishops who upheld their king in his evil ways, and even Hincmar of Rheims. His chief weapon against the bishops was a series of early decretals, now known to have been forgeries not emanating from Rome. The lofty policy of Nicolas was pursued, though with less success, by Hadrian II. (867–872). Meanwhile a dispute begun in the time of Nicolas was leading the Greek Church towards schism. During the papacy of John VIII. (872–882) the Saracens established themselves in Southern Italy and threatened Rome, and the courageous pope sought help on all sides against them and his Christian enemies. The anarchy in Italy which followed the extinction of the Carolingian empire had the worst effects on the papacy. Things were darkest in the first half of the 10th century. Competitors for power treated the popes as their tools, and elections to the papacy were decided either by the nobles of Rome, or the mob, or any foreign power which chanced to be master of the city. No reverence was paid to the papal office, and several of those raised to it were men of fierce and unholy lives. Pressed by enemies, John XII. sent for help to Otto the Great, king of Germany, and, by crowning him emperor in 962, revived the empire; he acknowledged Otto as his sovereign, and the Romans swore to elect no pope without the emperor's consent. Though Otto, his son, and his grandson did something towards restoring to the papacy its proper dignity, the attempt to regenerate it failed; and, after the death of Otto III., it was again degraded by falling under the control of the counts of Tusculum.

The emperor Henry III. regenerated the papacy by releasing it from the control of the Roman nobles, and conferring it on German churchmen of high character. One of these, Leo IX. (1049–55), commanded the respect of Christendom by his revival of ecclesiastical discipline. He was taken prisoner when attempting to check the Norman invaders of Italy, but the Normans reverenced their captive, and after his death acknowledged the pope as the feudal lord of their conquests, Sicily and Southern Italy. Under the guidance of Hildebrand (see GREGORY VII.) the papacy advanced rapidly in power and repute. By a decree of Nicolas II. (1059–61) in 1059 the right of election was vested in the cardinals. After a severe struggle clerical celibacy was enforced, and the clergy thus separated from worldly ties became devoted to the interests of their order and its earthly head. Simony was strictly repressed. A further advance was made when Gregory VII. (1073–86) forbade churchmen to receive investiture of their benefices from lay hands. This touched the sovereignty of lay princes. He was opposed by the Emperor Henry IV. (q.v.). The principle at stake was the church's independence of the lay power, its dependence on its own visible head, and its consequent salvation from feudal bonds and abuses. Gregory asserted the highest claims, and deposed the emperor, who made a humiliating submission at Canossa in 1077. Pope and emperor each found support, the pope in the discontent of the Germans and in the Normans. War broke out, an antipope and rivals to the emperor were set up. The struggle lasted beyond the lives of Gregory and Henry IV., and was decided in 1122 by the Concordat of Worms, which, though a compromise, was a substantial victory for the papacy. During the struggle the Crusades brought a vast increase of power to the pope, for they made him the head of Christendom in arms and the director of its forces. Though disturbed for a few years by a schism, the result of Roman faction, the reign of Innocent II. (1130–43) was a time of greatness. The religious orders had from the first rise of western monasticism been strong upholders of the papacy, and each order as it was founded laid its new-born zeal at the disposal of Rome. Innocent gained much from the support of St Bernard, backed by all the strength of the Cistercian order. Under Hadrian IV. (1154–59), a native of St Albans, named Nicolas Brakespear, the only Englishman who has been raised to the papal chair, the papacy entered on a struggle with the Emperor Frederick I., who was determined fully to enforce his imperial rights. In theory pope and emperor supplied each the complement of the other's power, the one being God's vicegerent in spiritual, the other in worldly things; but the limits dividing their spheres of action were undefinable, and when both were strong they were almost forced into hostility. Among the definite causes of dispute was the sovereignty of the pope over certain parts of Italy which had been bequeathed to the papacy by the Countess Matilda of Tuscany (died 1115). The popes were upheld by a league of the Lombard cities, which carried on a long war with the emperor; he was defeated, and in 1177 submitted to Alexander III.

The papal authority reached its greatest height under Innocent III. (1198–1216), who ruled as the head of a vast spiritual empire, founded on the

reverence of mankind for righteousness. He was master in Italy. His strife with two emperors ended in the success of his ward, Frederick II., inheritor of the Sicilian throne, whom he crowned emperor. By excommunication he forced the king of France to put away his paramour; he deposed John of England, and compelled him to become his vassal. The kings of many nations submitted to his rebukes. The Latin conquest of Constantinople brought the East for a while under the papal obedience, and a crusading army began to extirpate the heretics of Languedoc. More important than all was the foundation of the orders of St Dominic and St Francis, which gave the pope well-organised and generally devoted forces in every land. Innocent was the first pope that exercised full dominion over the States of the Church. Their position as temporal sovereigns brought his successors into collision with Frederick II., who, already king of Sicily and Naples, wished to gain Central Italy. Had he done so he would have made the papacy dependent on himself. Gregory IX. (1227–41) and Innocent IV. (1243–54) resisted him by every means, spiritual and temporal, at their disposal. The Italian cities of the Guelfic or papal party were their strongest allies. Innocent declared the emperor deposed, and found allies against him in Germany. The papal resources were strained; money was extorted from foreign countries, especially from England, and the papacy lost in repute by its demands. The struggle was continued against Frederick's house until it was extinguished. All danger of subjection to the empire was past; but the papacy owed its final success to Charles of Anjou, who was invested with the kingship of Sicily and Naples. This gave France an interest in Italy, and led to the subjection of the papacy to the French king. The imperial power having fallen, Boniface VIII. (1294–1303) sought to take the emperor's place as head of Europe. His aims were secular and his temper violent. National monarchies were being built up in England and France by strong kings. The claims of Boniface were subversive of their domestic policy; they refused to admit them, and he quarrelled with both kings. The Italian partisans of Philip IV. of France seized him; he was brutally treated, and died soon afterwards.

Philip procured the election of a Frenchman, Clement V. (1305–16), who resided at Avignon in Provence, afterwards sold to the papacy. There the papal court remained for about seventy years, a period called the 'Babylonish Captivity,' during which the popes were much under the influence of their powerful neighbour of France. A long struggle with the Emperor Louis IV., in which the popes were successful, injured the reputation of the papacy. During its course men began to criticise the character and claims of the papacy. It was attacked on ecclesiastical grounds by the 'Spiritual Franciscans,' and by scholars like Ockham, and on political by the imperial legists. The court at Avignon was luxurious and venal. Little revenue came from the States of the Church, which fell into disorder during the pope's absence, and large sums were raised from national churches and by corrupt means. Fearing to lose all authority in Italy, Gregory XI. returned to Rome in 1378, but died there immediately afterwards. Urban VI. was elected, but the French cardinals, supported by the king of France and the Angevin queen of Naples, rebelled, and elected Clement VII. During the schism which ensued the obedience of Europe was divided between rival popes. In order to heal the schism the cardinals revived the long disused authority of a general council. The Council of Pisa (1409) failed of its object. The reformation as well as the reunion of the church was largely desired. In England Wyclif urged apostolic poverty as the only cure for abuses. His teaching was of little practical importance, save that it helped forward the revolt of Bohemia, where the Slavs regarded the Latin liturgy as a badge of German superiority. Many orthodox churchmen desired to see the abuses of the papal court reformed and the churches of the several countries preserved from undue papal interference. By the Council of Constance the schism was closed, and Martin V. (1417–31) was elected pope; the council proved unequal to deal with reform. Martin's wise administration raised the papacy from its low estate; he regained its possessions, and made its power widely felt. The Bohemian war made another council inevitable; it met at Basel in 1432, it attacked Eugenius IV. (1431–47), raised up an antipope, and ended in contempt. Meanwhile the Greeks, hoping for help against the Turks, submitted to the holy see. In another respect the papacy was specially affected by the troubles of the Greeks. It readily adopted the learning and culture brought by the Greeks to Italy. The genius of Nicolas V. (1447–55) conceived a new ideal. The 15th century was an age of splendour; its magnificence was conspicuous in the lives not merely of princes, but even of nobles, merchants, and bankers. As the papacy outstripped all earthly powers in greatness, so in the mind of the pontiff was Rome its seat to impose on the imagination of all the world by an exterior grandeur which should outshine that of the city of any earthly potentate. But his was no vulgar ideal of mere magnificence; Rome to him was to be the protectress of the arts, the home of learning, the central point of culture in the Christian world; and all this was but to typify and render sensible the supremacy of religion.

Under Pius II. (1458–63) the pope again appeared as the natural head of the forces of Christendom united in arms against the infidel. Pius died when actually setting out on a crusade, and his plans failed, but they gave the papacy renewed importance in the eyes of Europe. His successors, inheriting generally the views of Nicolas V. in regard to Rome as the material expression of papal greatness, did not inherit the loftiness of his spirit. Whilst pursuing the idea of surrounding the papal dignity with pre-eminent splendour, some, like Paul II. (1464–71), betrayed a sympathy for the pagan renaissance which is unmistakable, and which cannot fail to have diminished the veneration due to the head of the church. Other popes, like Alexander VI. (1492–1503) or Julius II. (1503–13), were bent on founding in the Italian states princedoms either for their relatives or for the papal chair. This is specially true of Alexander (Borgia), whose earlier life had been immoral, and who as pope caused scandal by his undisguised love of worldly pleasures; whilst his son Cæsar, an able, unscrupulous man, made matters worse by his crimes.

Meantime the idea of reform had not slept—witness the activity of such a man as Cardinal Nicolas of Cusa; but efforts like his were inspired by individual minds of a specially lofty turn, and at most had the countenance of supreme authority; however widespread, they were local and were not that general 'reformation in head and members' which had been so loudly and so earnestly called for. The inevitable day of reckoning came, but in a guise which none expected. In place of reform the Protestant Reformation effected a ruthless breach with the past, and instead of the enforcement of the law of the church that law itself was repudiated. Events now convinced, but too late, the most unwilling minds that what priests and bishops, regulars and seculars, theologians and zealous laymen had pressed for had been indeed

the need of the time. Rome itself furnished a lamentable illustration of the ruin that had come upon the church. Clement VII. (1523–34), though he had his own political aims, was as a man not unworthy of his office, and by character the least able to bear the brunt of the storm; yet it was he who witnessed Rome ruthlessly sacked (1527), and that by the troops of Charles V., who during the first half of the 16th century was the mainstay of the Catholic cause, and by his dignity as then emperor-elect the recognised protector of the Roman Church. The impression made by this event on all religious minds is well expressed in the measured but weighty words of Cardinal Sadoleto. 'If those,' he writes, 'had done their duty on whom the obligation chiefly rested (I speak not of the pontiff whose virtues, mildness, and uprightness are known not as great merely but as admirable), the priesthood would still be venerated as of old, and not now exposed to injury and contempt. I say what I feel, and God and man are my witnesses, that this best of pontiffs desired to cure these corrupt morals; but the thing needed the knife, not a salve, and his nature and kindly spirit shrank from strong measures.'

From this point the history of the papacy to the close of the 18th century falls naturally into three divisions. From 1530 to the early years of the 17th century there takes place a reconstitution of the papacy on the basis of Catholic reform; next follows a century of normal activity on the new basis thus formed; thirdly, a century of decline in influence, the term of which is marked by the conclave in Venice which resulted in the election of Pope Pius VII.

(1) No time was lost in setting about the work which now all recognised as the imperative need. The papacy was not prominent in the work of reform; but the countenance given by Rome to men like Contarini, Pole, and Ghiberti is sufficient evidence that the popes themselves did not intend to be behindhand. The pontificate of Paul III. (1534–50) witnessed two events of considerable importance to the future of the church—the institution of the Jesuits, and the commencement of the Council of Trent. In 1534 Ignatius of Loyola pronounced his vows in the presence of the pope, and thus laid the foundations of a society of men specially devoted to the service of the holy see, with which its fortunes have subsequently been intimately associated. The ideal conceived by Ignatius was that of an order governed by 'a general whom all should be bound to obey under vow, who should be perpetual, possessed of absolute authority, subject entirely to the pope, but not liable to be restrained by any chapters of the order.' Paul III., on September 27, 1540, by the bull *Regimen militantis*, gave the papal approval to the 'form of life' designed by the founder. The Council of Trent, whatever be the import of its dogmatic definitions, is essentially a council of disciplinary reform; but in this place it requires notice as being a council of which, though held at a distance from Rome, the control and effective action really vested in the pope. After long negotiations the council convoked by Paul III. met at Trent in December 1545. As early as 1542 the papal legates had reached that city; but the war between France and Germany which then broke out made the further delay inevitable. It is worth remarking, as showing the influence already possessed by the newly-founded Society of Jesus, that two of its members came to the council as papal theologians. On April 28, 1552, the sittings of the fathers were suspended for two years. On November 29, 1560, the then pope, Pius IV., convoked it for the following Easter. The decree of reformation of morals and government, consisting of eighteen chapters, was adopted in the 23d session. It contained a number of important provisions on the residence of bishops and parish priests, upon the qualifications for the priesthood, and for the erection of seminaries for clerical training. In the 25th session was passed a series of regulations for the regular clergy and nuns. The decrees of the council were formally confirmed by Pius IV. in 1564. By its declarations on dogmatic theology the council gave prominence to the differences existing between Catholics and non-Catholics, and thus more sharply divided Christendom into the spiritual subjects and the enemies of the papacy. The cause of Catholic reform dominated the policy of Paul IV. (1555–59), and from his time the constitution of the Roman see in its modern aspect progressed practically without a check. In this period, too, falls the establishment of administrative bodies called 'sacred congregations,' which henceforth are the recognised and usual organs for the exercise of papal power in the government of the church. Lesser objects were not neglected. If modern Rome has been for so long the city in Europe which has attracted and deserved to attract the curiosity and admiration of all men, this is largely due to the continuation during this period of the works begun under the inspiration of Nicolas V. It is often forgotten that St Peter's itself was not completed till 1626.

(2) By the beginning of the 17th century the papacy as an institution had reconstituted itself in accordance with the circumstances induced by the Protestant Reformation. Its history in this second period shows no such stirring events as had marked the preceding age. But for its future the transfer of the weight of political power from the House of Austria to that of France was of decisive importance. The full consequences of the change were not, of course, perceived immediately, but it is certain it was recognised in Rome as momentous, and was not viewed with satisfaction.

(3) The conclave which assembled in Rome in the year 1700 determined the history of the papacy in the third period. Among the cardinals the one who enjoyed the most respect was the Dominican Cardinal Orsini, the head of a body of cardinals whose views are sufficiently indicated by the name given to them—the *Zelanti*. He was a man of illustrious family, dominated by a sense of duty in all things great and small, of slender intellectual capacity indeed, but endowed with a rare gift of discerning merit and capacity in others; free from petty jealousy, he knew how to gather round him men of ability, and how to use them when he had them. But the change in the balance of power effected during the 17th century determined the election of Cardinal Albani, to whom was given the whole weight of the influence of France. As Clement XI. (1700–21) he was in the most important acts of his reign inspired by Louis XIV. To outward appearance, in the first half of the 18th century, the position of the papacy in its relations with princes and peoples remained as it had been before. To some extent also it is certain that Benedict XIV. (1740–58), by a charm of character which impressed even one so keenly alive to the weak side of humanity as Walpole, staved off the evil day. But before his death the signs of disintegration were unmistakable. Throughout Europe luxury and an accompanying dissoluteness of manners had increased to shamelessness, whilst the school of infidelity in France was now fully organised and confident of victory. The full effect, moreover, of the displacement of the imperial House of Austria as the political prop of the church in favour of France now made itself manifest, and the Jansenist troubles of the 17th century bore bitter fruit. The whole church of France had become involved in the quarrel. On

the one side the bishops nominated by the king insisted, as in duty bound, upon the acceptation of the bull *Unigenitus* issued by Clement XI. in 1713, whilst on the other a large body of the clergy and a not less large body of the laity resisted a bull involving assent to a lengthy series of abstract theological propositions. Of the violence of these theological quarrels it is now almost impossible to form an idea, and more than one cool observer believed schism in France to be imminent. Thus, whilst the papacy needed every aid to stem the rising tide of infidelity, it found those on whose help it should have been able to depend involved in internecine conflict. The second half of the 18th century was for the papacy a slow agony, the successive stages of which do not call for notice here. By the suppression of the Jesuits the papacy not merely deprived itself of an able body of strenuous defenders, but cast by the very act dismay among the ranks of many devoted to the church. Moreover, the manner of the fall of the Society of Jesus was not calculated to lessen the weight of responsibility, or it may be said the odium, attaching to so grave an act. It fell with dignity, and the cruelties inflicted upon many of its members called forth in unlikely quarters sympathy for the victims. It was natural that onlookers should be more impressed by these more recent occurrences than by the long chain of events which had brought the holy see to view the suppression of the Order as inevitable.

Even the faithful House of Austria now fell away, and the Emperor Joseph II. assumed to himself and exercised functions which the popes had ever claimed as pertaining to the supreme ecclesiastical power. The fruitless journey of Pius VI. (1775–99) to confer with Joseph II. at Vienna in 1782 is the outward evidence of the humiliation of the papacy. Before long the Revolution which broke forth in France swept away king and priest and all established institutions in church and state, involving Catholic Europe in disorder. An outbreak in Rome, fomented by the agents of the French ambassador, forced the pope from Rome as a prisoner (1798); and, after his removal from one place of confinement to another, Pius VI. died at Valence on 29th August 1799, Napoleon having, two years before, in anticipation of his death, given orders that no successor should be elected, and that the papacy should be abolished.

A few words must still be given to the present and fourth period of the modern age of the papacy. Through the instrumentality of schismatic Russia the conclave of cardinals met in the monastery of St Giorgio Maggiore at Venice on the 1st of December 1799. The conclave lasted for nearly four months. Just as the conclave of 1700 was decisive as regards the fortunes of the papacy in the 18th century, so was this of 1800 as regards the 19th century. The possible candidates were numerous; the choice finally rested on the Benedictine cardinal, Chiaramonti. Nothing better illustrates the confusion of ecclesiastical ideas in the 18th century, or a chief source of the weakness of the church, induced by universal suspicion, than an accidental expression used by a member of the conclave, Cardinal Langini, in his private diary. Explaining the objections felt by some in the conclave to Chiaramonti, he notes under 12th March 1800, only two days before the election, 'Chiaramonti, as a Benedictine, being suspected of Jansenism.'

No one who reviews the history of the 19th century can doubt that events have justified the choice of the cardinals. After enduring shocks which to human eyes seemed to threaten its very existence, the papacy has become once more a factor of the greatest potency in the civilised world. That this is so is largely the result of the personal character of Chiaramonti, the new pope, who as Pius VII. (1800–23) combined a conciliatory temper with an unconquerable inflexibility when vital principles were involved. The history of his relations with Napoleon I. is sufficient of itself to explain how he, destitute apparently of all human help, won for himself the respect of those who would naturally have been the first to contest his spiritual authority. In the space of his pontificate he was able to restore the papacy to the position which it had held a hundred years before. Under him began that restoration of Catholic life and Catholic aim which has attracted some of the ablest intellects and most statesmanlike minds of the century to the service of the church; and under him and his successors was accumulated a reserve of Catholic strength which is one of the most interesting and remarkable features of the 19th century.

The successors of Pius VII. by the personal purity of their lives contributed greatly to advance this Catholic revival. The reigns of Leo XII. (1823–29), Pius VIII. (1829–30), and Gregory XVI. (1831–46) witnessed an increase of zeal on the part of the Roman Catholic clergy everywhere, and a marked development of the spirit of loyalty to the holy see both in them and in the ranks of the Catholic laity. In France the exertions of Montalembert, Lamennais, and others firmly established a new school, which, whilst professing enlightened liberal doctrines, was founded on the principle that complete and loyal submission to the teachings and direction of Rome was the first duty of every Catholic. In England the passing of the act for Catholic emancipation in 1829 gave liberty, and with it new life, to Roman Catholics.

Pius IX. (1846–78) was chosen to succeed Gregory XVI. He had generally been credited with advanced liberal views, and had exerted himself during the civil disturbances under his predecessor to secure some mitigation of the punishments meted out to the political prisoners. He began his rule with a proclamation of general amnesty for such offenders, and for the first two years he maintained a policy of liberal political reform. At the end of that time he had practically become a prisoner in the hands of the revolutionary party, and on November 24, 1848, he escaped in disguise from Rome to Gaeta. Here he remained till in April 1850 he was brought back to Rome by the French troops. On September 29, 1850, he took the important step, as regards the English Catholics, of establishing a hierarchy of bishops in communion with the Roman see. On December 8, 1854, he issued the bull *Ineffabilis Deus*, by which the doctrine of the Immaculate Conception of the Blessed Virgin Mary was declared to be a dogma of the Christian faith. Ten years later (December 1864) he published the famous encyclical *Quanta cura*, together with the *Syllabus*, or catalogue of errors of the day which called for special condemnation. Romagna, a portion of the pontifical states, was occupied by the Sardinian troops in 1860, and in September of the same year, after a stubborn resistance made by the pope's troops at Ancona, most of the States of the Church were annexed to the kingdom of Victor Emmanuel. From that time till 1870 Pius IX. was maintained in Rome by a French garrison. On the 18th of July of that year (1870) the Vatican Council, which the pope had assembled at Rome, decreed the dogma of Papal Infallibility part of the faith of the church. Upon the outbreak of the war between France and Prussia the French garrison was withdrawn from Rome, and on the news of the defeat of the French the Sardinian troops moved upon Rome. After a slight show of resistance Victor Emmanuel's army entered the city on the 21st September 1870, and from that time the temporal power of the pope has

ceased to exist. Pius IX. for the rest of his life remained in the Vatican, refusing to recognise what had been done. The position in which he was thus placed as a virtual prisoner in his palace aroused the sympathy of the Catholic world at large.

Leo XIII. (1878), who was chosen as his successor, has since continued to maintain towards the kingdom of Italy the attitude taken up by Pius IX. Although shut up in the Vatican palace, Pope Leo has possessed himself of an influence which has made itself felt, and has won for himself the respect of European powers. In Germany his wise diplomacy brought about a mitigation of the anti-Catholic 'May Laws.' In a question of disputed rights over the Caroline Islands his arbitration was sought by Germany and Spain, and his award accepted as final. The state of Ireland caused him to despatch thither a special envoy to study on the spot and report to him the nature of the agrarian difficulties which had arisen there, and the attitude of the Catholic clergy towards the grave questions involved in the struggle between the landlords and tenants. As a result of this mission, in May 1888 the pontiff issued a circular to the bishops of Ireland in which he condemned as immoral boycotting and the Plan of Campaign. In June 1891 the pope published an encyclical, addressed to the Catholic bishops, dealing with the principles which should govern the consideration of the questions involved in struggles between capital and labour.

Pope, ALEXANDER, the greatest poet of his age, and the most brilliant satirist that England, or perhaps the world, has ever produced, was born in London on the 21st of May 1688. He was of good middle-class parentage, but not, as he afterwards characteristically endeavoured to make out, of aristocratic descent. His grandfather, Alexander Pope the elder—whose pedigree he attempted to derive, though on very inadequate evidence, from the Earls of Doune—was a clergyman of the Church of England. His son, the poet's father, was placed with a merchant at Lisbon, where he became a convert to the Roman Catholic Church. On his return from Lisbon he seems to have followed the trade of a linen-draper in Broad Street, whence, after his marriage with Edith Turner, the poet's mother, he migrated to Lombard Street. Here, on the above-mentioned date—once the subject of much perplexing controversy, but now satisfactorily ascertained—Alexander the younger first saw the light. In his infancy, and indeed up to the age of ten, he does not seem to have been either weakly or deformed. In the opinion of a kinsman, 'it was the perpetual application he fell into in his twelfth year that changed his form and ruined his constitution;' and it is possible that this may have contributed to and aggravated a misfortune which could hardly have been due to any such cause alone. It is at any rate certain that Pope's application to study must have been both early and intense, for deep traces of thought and culture are no less conspicuous than natural precocity of genius even in his most juvenile poems; and he certainly owed little to his teachers. His education, thanks no doubt to the disabilities created by his inherited creed, was unmethodical and imperfect to the last degree. He seems to have passed from one incapable Catholic priest and ill-ordered Catholic seminary to another, until at twelve years of age he was removed, knowing little more apparently than the Latin and Greek rudiments, to Binfield near Wokingham, to which place his father had by that time retired. Yet in this very year he wrote his *Ode on Solitude*, an insignificant but not unpromising performance, and at fourteen, according to his own account, he composed the poem on *Silence*, in imitation of Rochester's *Nothing*, which both in manner and matter is astonishingly mature. It was at the same age that he produced the first of his works which attracted attention, a *Translation of the First Book of the Thebais of Statius*, a poem memorable above its intrinsic merits from the fact that in it the English heroic couplet, though of course falling far short of the technical perfection to which Pope afterwards brought it, is already beginning to take the new mould into which, in his hands, it was destined to be recast. It is during the next two years, that is to say, at the marvellously early age of from sixteen to eighteen, that Pope's career as a recognised English poet may be said to begin. For it was at some time during these years (1704–6) that he wrote his *Pastorals*, which, though not published till 1709, were shown to and highly commended by all the leading critics of the day, and were the means of bringing their young author acquainted with the dramatist Wycherley, then advanced in years, with whom he commenced a singular correspondence, the tenor of which he audaciously misrepresented in later life.

It was to Wycherley, too, that Pope owed his first introduction, which took place a little later, to London life, where the youth's extraordinary talents were quickly recognised, and where he was not long in establishing a friendship with Addison, Steele, Swift, Arbuthnot, and other famous wits and poets of the day. In 1711 he published his *Essay on Criticism*, a poem which, whether written in 1709 or 1707—and it may have been his invincible habit of committing small acts of dishonesty for still smaller gains that suggested the antedating of the composition—was a sufficiently splendid achievement for the age either of nineteen or twenty-one. It at once, or nearly at once—for it hung for a little at first at the booksellers—placed him in the front rank of the men of letters of his time. Critical opinions differed, and down to our own day have continued to differ, as to the degree of merit possessed by this remarkable poem in respect of its matter—some depreciating its critical aphorisms as platitudes, others elevating them into utterances of gnomic wisdom; but its excellences of form are not open to question in any competent judgment. Young as was its author, even on the highest computation of his age, his style had already reached maturity, and his matchless power of expression is here exhibited, if over a less varied subject-matter, yet certainly with a no less unerring mastery than in any of his later works. The year 1713 witnessed the publication of *Windsor Forest* (written, according to Pope's account adopted by Warburton, in 1709), a piece much admired in its day for the accuracy and force in its descriptions of nature; and this was succeeded in the following year by the poem on which Pope's claim to the gift of poetic imagination may perhaps be most securely rested, the *Rape of the Lock*. Necessarily precluded by the deliberate triviality of its subject from appealing to the higher emotions which imaginative poetry of the serious order arouses, this piece displays, in addition to the exquisite charm of its versification, a grace of delicate fancy which at times almost recalls the creator of Puck and Ariel, and the diviner of the dream-whispers of Queen Mab.

We now reach the commencement of what was probably the happiest and most prosperous period of the poet's life. His brilliant success had not yet brought with it much pecuniary profit, but in the year 1713 a project was set on foot by him, and warmly supported by Swift and others of his friends, which was destined not only to add to his fame, but to place his fortunes on a substantial basis for life. This was the translation of the *Iliad*, a work published by subscription, in six volumes, intended to appear yearly; the last two, as a matter of fact, were issued together after six years' intermission in 1720. Most imperfectly representative, as might be expected, of its great original, it is nevertheless a poem so remarkable for its union of force and elegance, and one which moves with an animation so inspiriting and unflagging, that it can be read to-day with no inconsiderable portion of the pleasure which it gave to the contemporaries of the poet. The year of its composition was among the fullest and busiest of Pope's life. In 1716 his father removed from Binfield to a house at Chiswick, where he resided till his death in the following year. Pope was now the foremost of the literary lions of fashionable London, and almost as conspicuous a personage in the drawing-rooms of ministers and magistrates as in the coffee-houses of the wits. At this period, too, his mind, save for an interval of natural grief at the loss of his father, was probably as easy as his circumstances. Political differences, aggravated by well or ill-founded suspicions of the elder writer's jealousy of the younger, had alienated Pope from Addison; but, though he had already begun his almost life-long quarrel with the eccentric John Dennis, it had not yet taken on a character of any very extreme virulence. In 1718 he purchased out of the early profits of the *Iliad* the famous villa and grounds at Twickenham, which he occupied till his death.

A translation of the *Odyssey*, less successful because largely 'farmed out' to inferior hands, was

published in 1725 and the following years; and in 1727 appeared the first two volumes of a collection of *Miscellanies*, from the joint authorship of Pope and Swift, a work famous as being the first shot fired in the war between the poet and 'the Dunces.' In March 1728 the third volume appeared, and the furious and scurrilous retorts wrung from the persons ridiculed in it elicited the retaliatory publication of the first three books of the *Dunciad*. This work Pope represented as having been written in reply to their attacks, but it (or a first draft of which) has been ascertained by recent inquiry to have been in existence as early as 1725, and to have been merely withheld until its author had deliberately stung his enemies into a blind and headlong charge. 'Martinus Scriblerus,' in fact, played the part of the lance with which the Spanish picador irritates the bull to frenzy; the *Dunciad* was the blade poised ready to transfix him. In this immortal lampoon—for it is too personal in all senses of the word to deserve the title of satire—Pope has rescued the names of a host of insignificant enemies from oblivion; and it is the highest tribute to the extraordinary artistic power of this poem that it can still be read with a pleasure unimpaired by the absolute obscurity of most of its heroes. The fourth book, added twelve years later, is of a more serious cast and of a more general application, and it contains one at least of the poet's most admired passages. But its incorporation with the earlier poem, with its infelicitous substitution of Cibber for Theobald as the personification of Dullness, is to be regretted. The *Essay on Man*, the first part of which was published in 1733, the *Moral Essays*, and *The Imitations of Horace* conclude the catalogue of Pope's poetic works. The first, a didactic poem, intended to commend to the world the not very profound philosophy which Pope had borrowed from Bolingbroke, is from the point of view of execution a masterpiece of weight and wit. The poet's mastery of terse and epigrammatic expression is here seen at its highest; and it has been declared, no doubt with truth, that the *Essay on Man* contains more lines which have won their way to the rank of universally familiar quotation than any poem of equal length in the language. The *Moral Essays* and the *Imitations* exhibited the same qualities exercised upon a series of selected subjects of, for the most part, a lighter order; and, as in the case of the still more famous *Essay on Man*, it is almost impossible to open a page without coming upon a line or a couplet which has become a household word.

The last few years of Pope's life were marked by no new creative activity, but devoted to the revision of his published works. He suffered during this period from asthma, which in time developed dropsy, a disease which ultimately proved fatal to him. He died on the 30th of May 1744, at the age of fifty-six, leaving behind him a literary fame which, despite the change of taste in poetry, has undergone no eclipse in a century and a half. As a man the figure which he presented to all but a few close friends was always an unamiable one, and modern research into the facts of his life has unfortunately only tended to deepen the impression. It cannot be denied that many of the smaller and meaner vices of humanity were painfully prominent in the character of Pope. His vanity was insatiable, and his vindictiveness came near to be so: he committed acts of treachery to men, brutality to women, and ingratitude to both. He showed an extraordinary and at times an almost ludicrous preference for the crooked to the straight path, and much of his time was occupied in laying elaborate plots for the deception of posterity and his contemporary public, including sometimes his most intimate friends. Yet it is certain that to these last he must have revealed many lovable qualities. He was undoubtedly capable of warm attachment, and his disposition when appealed to by the sight of want or suffering was genuinely benevolent. It should be remembered, too, in excuse for the acrimony of his satire, that physical misfortune and accidents of bringing up had combined to render him morbidly sensitive to the insults of his adversaries, and that his revenge was not more cruel than his sufferings.

The position of Pope in the history of poetry is easier to fix than his rank among English poets; and the historian of literature can in these days assign him a far higher place without fear of challenge than any critical admirer, however ardent, can hope to secure for him in contemporary esteem. For the importance and splendour of Pope's contribution to the development of English *poetic art* are beyond the denial of any one conversant with the facts. It is a truth superior to and independent of the endless and irreconcilable controversy as to the essence and 'true inwardness' of *poetic matter*. The poets of the naturalist revival at the end of the 18th century regarded Pope as the brilliant exponent of a false and artificial theory of poetry who had systematically, though of course unconsciously, led men away from the contemplation of the 'true truth' of things. It has on the other hand been contended with much learning and ingenuity by Mr Courthope that Pope's theory of poetry, if compared with that which it displaced, was a no less distinct and salutary return to nature than that of which Cowper became the pioneer in the later half of the century, and which Wordsworth preached and practised with such notable results towards its close. But even if this contention leaves us unconvinced, we can still find abundant reason for recognising as invaluable the services rendered by Pope to English poetry. He was virtually the inventor and artificer who added a new instrument of music to its majestic orchestra, a new weapon of expression to its noble armoury. Considered from the point of view of its descriptive and emotional capabilities, the heroic couplet as he received it from the hands of Dryden was an instrument of vast compass but of modulations few and rude. By force of exquisite sensibility wedded to untiring study Pope theoretically deduced and practically educed its hidden powers, discovered, formulated, and inimitably applied the rules for 'discoursing' upon it; and handed it on to posterity in a form whose easy mechanical perfection is attested by the fact that its powers are but too much within the reach of the inferior performer. Considered as a weapon of expression, the heroic couplet of Dryden was a mediæval broadsword which only the mighty thews of its master could wield with any effect. In the hands of Pope it became a rapier of perfect flexibility and temper; and he himself discovered, and acquired mastery over, every trick of fence which it was capable of executing. To have accomplished this alone would have sufficed to perpetuate his name; but Pope has lived and will live in English literature, not only as the virtual inventor of a new poetic form, but as an artist without a rival in any age or language in the adaptation of speech to thought. No one who brings a fairly sympathetic mind to the perusal of the *Epistle of Eloisa to Abelard* will deny to Pope a measure of the lyrical gift and no mean power over the softer emotions. But one must admit that to the taste of the present age there occurs a certain coldness and artificiality in his portrayals alike of the face of nature and of the passions of man. He appeals rather to the brain than to the heart. Ideas and not emotions are his province; but to the metric presentment of ideas he imparts a charm of musical utterance unachieved before his time, and a lucidity

of illustration, a brilliancy of wit, a command of apt and terse expression, and a combined ease and dignity of manner which have never been equalled since. To have done this is to have well deserved immortality as a man of letters; whether it is also to have established a title to the name of 'poet,' as understood in these days, every man who frames his own definition of poetry must decide for himself.

The editions of Pope have been fairly numerous. The first, by his friend Bishop Warburton, was an answer to Bolingbroke's attack on Pope's memory, and appeared within a few years of his death. Dr Joseph Warton's was virtually a reply to Warburton's; and the controversy on the power of the poet was revived in the 19th century by Bowles and Roscoe, who each published an edition of his works, and in whose polemics Byron took a memorable part. All other editions, however, have been superseded by that of the Rev. Whitwell Elwin and Mr W. J. Courthope, which was founded on a mass of documentary material collected by the late J. W. Croker; the concluding volume, containing Mr Courthope's biography of the author, was published in 1889. The annotations of the poems are rich and valuable, and the Life disposes finally of many questions concerning Pope's character and career which all his earlier biographers had lacked the material and some the critical impartiality to determine.

Pope, John, an American general, was born in Louisville, Kentucky, 16th March 1822, graduated at West Point in 1842, and entered the engineers. He served in Florida (1842–44) and in the Mexican war, and was brevetted captain for gallantry. He was afterwards employed in exploring and surveying in the west, until the outbreak of the civil war, when he was appointed brigadier-general of volunteers. In 1861 he drove the guerillas out of Missouri; in 1862 he captured New Madrid in March and was made major-general, commanded the Army of the Mississippi in the operations against Corinth, and was assigned to the command of the Army of Virginia, with the rank of brigadier in the regular army. For fifteen days in August he faced Lee, but was defeated at the second battle of Bull Run, on the 29th and 30th. He then requested to be relieved, and was transferred to Minnesota, where he kept the Indians in check. He held various commands until 1886, when he retired. In 1882 he became major-general. Pope attributed his defeat at Bull Run to the conduct of General Fitz-John Porter, who was tried by court-martial and cashiered; but this verdict occasioned much controversy, in which General Grant ultimately took Porter's side (*American Review*, December 1882), and in 1886 the latter was restored to the army with the rank of colonel.

Poperinghe, an old commercial town of Belgium, in the province of West Flanders, 4 miles from the French frontier, and 8 miles W. of Ypres by rail. The town has manufactures of lace, linens, and woollen cloths. Pop. 11,065.

Popinjay (Fr. *papegai*, Ital. *papagallo*, Low Gr. *papagas*), a parrot; a figure of a bird put up as a mark for archers to shoot at (*papingo* being another Scottish form for this sense); see Kilwinning. The green woodpecker is also sometimes called popinjay.

Popish Plot, the name given to an imaginary plot on the part of the Roman Catholics in England during the reign of Charles II., the object of which was believed to be a general massacre of the Protestants. See Oates.

Poplar (*Populus*), a genus of trees, forming along with willows the whole of the natural order Salicaceæ or Salicineæ (by some regarded as a suborder of Amentaceæ), and having dioecious flowers arranged in catkins, both male and female flowers with an oblique cup-shaped perianth. The seeds have silky hairs, as in willows, and are readily wafted about by the wind. The species are numerous, chiefly natives of the temperate and cold regions of the northern hemisphere. They are large trees of rapid growth, with soft wood, and broad, heart-shaped, ovate, triangular, or lozenge-shaped, deciduous leaves, on rather long stalks. Many of them are very beautiful trees. The catkins appear long before the leaves, and proceed from distinct lateral buds. Few of the poplars are of much value for their timber, which is generally white, soft, and light; but from their rapid growth they are useful as yielding firewood, where the scarcity of other fuel renders it necessary to plant trees for this purpose, and they are often planted as ornamental trees, producing an immediate effect of embellishment in a bare situation more readily than almost any other kind of tree. Besides the species known by the name Aspen (q.v.), or Tremulous Poplar, the following seem the most worthy of notice. The White Poplar, or Abele (*P. alba*), a native of the southern parts of Europe, and reckoned among British trees, but probably not indigenous in Britain, is a tree of 80 feet or upwards, with a fine spreading head, and roundish, heart-shaped, lobed, and toothed leaves, which are smooth, shining, and dark-green above, downy and silvery-white beneath. The wood is used by cabinet-makers, turners, and toy-makers. It is little liable to swell or shrink, and this fact adapts it for various purposes. The tree loves low situations and clay soils. This tree has of late years suffered in Britain from some unknown cause, like the potato, dying where it previously flourished; whilst other poplars, the most nearly allied, continue to flourish in the same localities. The Gray Poplar (*P. canescens*) is very similar to the white poplar, but of more vigorous growth, a large spreading tree, the leaves similar to those of the white poplar, but not so dark green above or so white beneath. It is not of so rapid growth as the white poplar; and its wood is harder and better, makes good flooring, and is preferable to pine-deal for the neighbourhood of fireplaces, being less apt to take fire; it is also used for coarse doors, carts, barrows, &c., and, not being liable to warp, is esteemed by woodcarvers. The tree generally begins to rot in the heart when forty or fifty years old. Like most of the other poplars, it fills the ground around it with suckers. Like the white poplar, it is a very doubtful native of Britain, and belongs to the centre and south of Europe. The Black Poplar (*P. nigra*), a native of most parts of Europe, and perhaps of England, is a tree 50 to 80 feet high, with an ample spreading head, viscous leaf-buds, and deltoid or unequally quadrangular, perfectly smooth leaves. The wood is used for the same purposes as that of the white and gray poplars. The 'cotton' from the seeds has been used in France and Germany for making cloth hats and paper, but these uses of it were not found profitable. The Lombardy Poplar (*P. fastigiata* or *dilatata*) is a mere variety of the black poplar, with erect instead of spreading branches. It

Branch and Male Catkin of *Populus alba canescens.*

appears to have been introduced into Europe from the East. It is very common in the Punjab and in Persia, and now also in Lombardy and other parts of Italy. It attains a height of 100, or even 150 feet, and is remarkable for its erect form, contracted head, and very rapid growth. It is often planted as an ornamental tree, although not so generally as in the end of the 18th century, when it was thought preferable for ornamental purposes to every other tree. It is common in the streets and squares of towns in Britain, and is particularly adapted to situations where a long horizontal line of any kind fatigues the eye, or where it is seen starting up from a mass of lower wood or shrubbery. The wood is almost of no value. It is generally propagated by layers. The species commonly known as Black Italian Poplar (*P. monilifera* or *acladesca*), although it is really a native not of Italy, but of North America, and is sometimes more correctly called Canadian Poplar, the female catkins of which resemble a string of pearls, is frequently planted both as an ornamental tree and for the sake of its timber, which is useful for flooring, &c. The leaves are deltoid. It is of very rapid growth, and attains a height of 100 to 120 feet. The Balsam Poplar, or Tacamahac (*P. balsamifera*), a very common ornamental tree in Britain, is a native both of North America and of Siberia, and has ovate-oblong leaves, which in spring are of a delicate yellow tint, and have an agreeable fragrance. The leaf-buds are viscid. The resinous exudation of the buds (Tacamahac, q.v.) is said to be diuretic and anti-spasmodic; and an ointment made from the buds is used for tumours, wounds, and burns. The resinous exudation of the buds of other species, as the black poplar, possesses similar properties. The Cottonwood (*P. canadensis*) of North America, particularly abundant on the upper parts of the Mississippi and Missouri, is valued as a timber-tree, and has been pretty extensively planted in Britain; as has also the Ontario Poplar (*P. candicans*), a species with the same balsamic character as *P. balsamifera*, and chiefly distinguished from it by its larger leaves. In size of leaf no other species equals *P. heterophylla*, a native of the southern states of North America, the leaves of which are often 6 inches long. See ASPEN.

Poplin (Fr. *papeline;* possibly from the town of Poperinghe, of which an old spelling is Popeling), a fabric which has been long made in France, from which country the manufacture was introduced into England and Ireland in the 17th century by Protestant refugees. Poplin consists of a warp of silk and a weft of worsted, and the latter being thicker than the former produces a corded appearance. The worsted yarn gives substance to the fabric, and a soft silky face is produced by the way in which it is woven. Poplins may be either plain or figured. The Irish poplins are nearly all made in Dublin; the industry has been subject to great fluctuations, notwithstanding the efforts to foster it. Figured poplins, which were much used about 1870 for curtains and covering furniture, are at the present time, in Great Britain at least, employed for these purposes only to a limited extent.

Popocatepetl ('smoking mountain'), a volcano about 40 miles SE. of the city of Mexico. It rises in the form of a cone to a height of 17,784 feet above the sea-level. No eruption has been recorded since 1540; it still smokes, however. It is often sealed, and in and around its crater (5165 feet in diameter, and nearly 1000 deep) a good deal of sulphur is obtained.

Poppy (*Papaver*), a genus of plants of the natural order Papaveraceæ, having a calyx of two (or rarely three) sepals, which very soon fall off; a corolla of four (rarely six) petals; numerous stamens seated on a receptacle; the stigma crowning the ovary, without a style, and in the form of 4 to 20 rays; the capsule opening by pores under the persistent stigma, imperfectly divided into cells by partitions as numerous as the rays of the stigma, but which do not reach the centre, and the seeds extremely numerous. There are numerous species of poppy, mostly natives of Europe and Asia, some of them found even in very northern regions, but most of them in the warmer temperate parts. They are herbaceous plants, annual, biennial, or perennial, mostly sprinkled with bristly hairs. They have a white milky juice; a disagreeable narcotic smell, particularly when bruised; pinnatifid or bipinnatifid leaves, more rarely jagged or toothed leaves; and large showy flowers, which readily

Opium Poppy (*Papaver somniferum*):
a, whole plant; *b*, flower and leaf; *c*, ripe capsule; *d*, seed and section of do. enlarged. (Bentley and Trimen.)

become double by cultivation. The capsules are curious from the manner in which they fling out their seeds when the plant is shaken by the wind; each capsule being somewhat like a round or oval pepper-box, with holes, however, not in the top, where rain might get in by them, but under the projecting rim. By far the most important species is that known as the Opium Poppy (*P. somniferum*), also called the White Poppy and the Oil Poppy (see OPIUM). But the same species is important on account of the bland fixed oil of the seeds, and is much cultivated as an oil-plant. *Poppy-oil* is as sweet as olive-oil, and is used for similar purposes. It is imported into Britain in considerable quantities from India. The poppy is also extensively cultivated for it in France, Belgium, and Germany. The use and manufacture of this oil were for a long time, during the 18th century, strictly prohibited in France, from a mistaken notion that it must partake of the narcotic properties of the milky juice of the plant. The seed, however, contains no opium or any narcotic principle, and was well known to the ancients as a pleasant article of food, fit to be eaten by itself or with bread; some German cakes have poppy-seed plentifully sprinkled on the top. The oil expressed from it is perfectly wholesome, and is much used in

France and elsewhere as an article of food. It is believed that one-half of the oil used for cooking and otherwise for alimentary purposes in France is of this kind. The seeds yield about 40 per cent. of oil, and the oil-cake is useful for manure or for feeding cattle. The oil is sometimes used by painters and by soap-boilers; but it is not good for burning. In the cultivation of the poppy for oil the seed is often sown in autumn, where the severity of winter-frosts is not to be feared; in more northern parts it is sown in spring, and sometimes the seed is scattered on the top of the snow with which the ground is covered. Being very small it needs little or no harrowing. Early sowing is favourable to the size of the plant and the abundance of produce. Hoeing and thinning are advantageous. An open but rich soil is best for the poppy; and a sheltered situation is necessary, as in exposed situations much of the seed is scattered by the wind. The poppy does not exhaust the land so much as colza, rape, and some other oil-plants. Harvesting ought to begin when one-fourth of the capsules of each plant are open. It is accomplished by pulling the plants in such a manner as not to shake the seed out of the capsules, and tying them in sheafs, which are placed together in an erect or slightly sloping position, till the ripening of the capsules is completed, when the seed is taken out by shaking the capsules into a tub or on a cloth, great care being used to prevent any earth from the roots from getting mixed with them. Some farmers in Flanders sow poppies in alternate rows with carrots. The variety of poppy chiefly cultivated as an oil-plant has flowers of a dull reddish colour, large oblong capsules, and brownish seeds; but the white-flowered variety, with globular capsules and white seeds, is also used. The Oriental Poppy (*P. orientale*), a native of Armenia and the Caucasus, a perennial species, is often planted in gardens on account of its very large, fiery-red flowers. Its unripe capsules have an acrid, almost burning taste, but are eaten by the Turks, and opium is extracted from them. Several species are British, all of them local, rare in some places, and troublesome weeds in cornfields in other places apparently quite similar in climate. Among them is the Corn Poppy or Common Red Poppy (*P. rhoeas*), with bright-red flowers, and deeply pinnatifid leaves. The petals are mucilaginous and slightly bitter; they have a slight narcotic smell; and a syrup made of them is sometimes used as an anodyne in catarrhs and children's complaints; but they are more valued for the rich red colour which they yield. A variety with double flowers is cultivated in flower-gardens, under the name of *Carnation Poppy*. Among the ancients the poppy was sacred to Ceres.

Poppy-head. See PEWS.

Population. Information as to the population of the various communities of the world will be found in the paragraphs dealing with the subject in the articles in this work on the various kingdoms and countries, ancient and modern, and on the several provinces of those countries, and on the towns and cities of the world; at EUROPE, ASIA, AMERICA, will be found tables of the population of the several countries in those great divisions of the world, so far as ascertainable. The population of the world (estimated by Behm and Wagner in 1882 at 1434 millions) will be dealt with at WORLD. The so-called 'population question' is discussed at MALTHUS; and other articles that deal more or less directly with population, its enumeration and fluctuations, are CENSUS, REGISTRATION (of Births, Deaths, and Marriages), and VITAL STATISTICS. For mortality tables, see INSURANCE. And questions that emerge in connection with the increase and density of population will be found treated at CORN LAWS, CROFTERS, EMIGRATION, FREE TRADE, INFANTICIDE, LAND LAWS, POLITICAL ECONOMY, POOR-LAWS, SOCIALISM, &c. And see works by Farr (q.v.), Quetelet (q.v.), Behm (q.v.), Bodio, Block.

Porbeagle, sometimes called 'Beaumaris Shark' (*Lamna cornubica*), is a shark found on the British coasts, in the Atlantic, Mediterranean, on the American coast, and in Japanese waters. Its usual length is 4 feet, but it sometimes attains a length of 10 feet, and is sometimes caught in mackerel and salmon nets, and even on haddock lines. It lives on cuttle-fish, pilchards, herrings, hake, and smaller cartilaginous fishes. In Mediterranean countries it is eaten as human food.

Porcelain. See POTTERY.

Porcellanite, a very hard, impure, jaspideous rock, frequently met with in the immediate vicinity of intrusive eruptive masses. In most cases porcellanite is simply a highly baked and altered argillaceous rock—shales being frequently converted into porcellanite along their line of junction with an igneous rock.

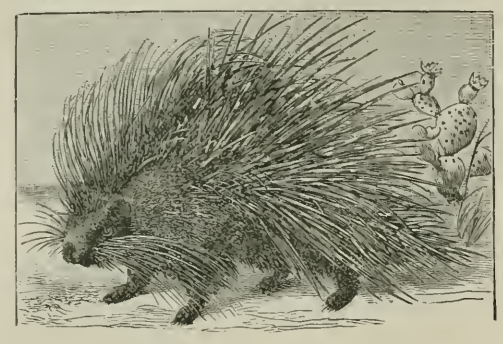
Porch, a building forming an enclosure or protection for a doorway. In mediæval and Elizabethan architecture the porch was very common in domestic architecture. In churches it was almost universal in England, most often on the south side

Porch of Aldham, Essex (1350).

of the nave, of stone or flint-work (in East Anglia), but sometimes also of wood. In France many splendid porches or portals remain; they are amongst the most beautiful specimens of mediæval art. See also GALILEE.

Porcupine, a name given to all the members of a family of Rodentia—the Hystricidæ. This family contains a number of well-defined genera, which include a good many species. The Common Porcupine (*Hystrix cristata*) is found in southern Europe, as well as in Asia and Africa, and is one of the largest of rodents; it has a heavy aspect and a grunting voice, whence the name Porcupine (from the French *porc*, 'a hog,' and *épin*, 'a spine'). The porcupines of the New World are sometimes included in a separate family; they comprise two well-marked forms—the Urson (*Erethizon dorsatus*) of North America and the Prehensile-tailed Tree Porcupines (Cercobates) of South America. The most marked peculiarity of the porcupine is of course the presence of the quills, which are simply thickened hairs; gradations between ordinary hairs and the thickest and longest spines exist to

prove this statement. Occasionally the spines end in a peculiar cup-shaped extremity. The armature of spines is of the greatest value to the porcupine, though their use is entirely for defensive purposes. It is hardly necessary to deny the popular belief that the animal can shoot out its quills like so many arrows; the notion has arisen from the fact



Common Porcupine (*Hystrix cristata*).

that when the animal erects its spines loose ones sometimes fall out. See ECHIDNA, GLOBE-FISH.

Pordage. See PHILADELPHIANS.

Pordenone, IL, a name for the religious painter Giovanni Antonio Licinio (1483–1539), born near Pordenone in Venetia.

Porifera. See SPONGE.

Porism is defined by Simson as a proposition to demonstrate that some one thing or more things are given, to which, as also to each of innumerable other things, not indeed given, but having the same relation to those which are given, it is to be shown that there belongs some common affection described in the proposition. Playfair defined a porism to be a proposition affirming the possibility of finding such conditions as will render a certain problem capable of innumerable solutions. Owing to the loss of Euclid's three books on porisms, and the obscurity of the account given by Pappus of their contents, there has been much discussion among geometers as to the nature of a porism. The two most important books on the subject are Simson's *De Porismatibus* in his *Opera Reliqua* (1776), and Chasles's *Les trois livres de Porismes d'Euclide* (1860). Chasles is of opinion that the porisms were closely allied to the modern theories of anharmonic ratio, homographic division, and involution.

Pork. See PIG for the animal from which pork is procured; DIET and FOOD for the properties of pork as an article of food; and TRICHINOSIS for one of the gravest of the diseases affecting the pig. The great headquarters of the trade in pork is the United States. This is partly indicated by the figures given at CHICAGO and HAM; but it will be shown more clearly by the following figures. In 1890 the total number of pigs in the United Kingdom was 2,773,609; in the United States it was in the same year 51,602,780, with a value of $243,418,336. While Britain imports pigs and pig-products (hams, bacon, pork, and lard) to a large extent (mainly from America), the United States exports on a vast scale. In the fiscal year 1889–90 the exports were as follows: hogs, 91,148; bacon, 531,899,677 lb.; hams, 76,591,279 lb.; fresh pork, 279,463 lb.; pickled pork, 79,788,868 lb.; lard, 471,083,598 lb. The value of these pig-products in that one year 1889–90 was over $67,070,000.

Porosity. By this term we express the experimental fact that no kind of matter completely fills the space it occupies. On the atomic theory it is obvious that this must be the case if the atoms of matter are spherical, or, indeed, if they have any form save one or two special ones, such as cubes or rhombic dodecahedrons. The Florentine Academicians, in their attempts to compress water, proved the porosity of silver by flattening a sphere of that metal, filled with water and soldered. The water escaped through the silver, and stood in fine drops on its surface. The porosity of liquids is easily shown by mixing alcohol and water. The bulk of the mixture is considerably less than the sum of the bulks of the components.

Porous Jars. See REFRIGERATION.

Porphyrite, one of the crystalline igneous rocks. It consists principally of plagioclase. The ground-mass of the rock is composed of microlites and minute rod-like crystals of plagioclase, interspersed amongst which may occur crystalline granules of hornblende, augite, rhombic pyroxene, mica, ilmenite, magnetite, &c. Sometimes traces of a glassy or devitrified base can be detected. Throughout this ground-mass are scattered porphyritically larger crystals of plagioclase, accompanied by one or more of the following minerals: hornblende, augite, rhombic pyroxene, mica, &c. The rock shows all varieties of colour, and ranges in texture from vitreous and cryptocrystalline up to coarsely crystalline. It is often vesicular and amygdaloidal. It occurs abundantly in Scotland (where it forms many of the hill-ranges of the Lowlands), both in the form of lava-flows and intrusive sheets, dykes, and masses. Porphyrite is so closely allied to Andesite (q.v.) that it may be considered as merely an altered variety of that rock.

Porphyrogenitus (Gr., 'born in the purple'), a title given to the Byzantine emperor Constantine VII. (912–959).

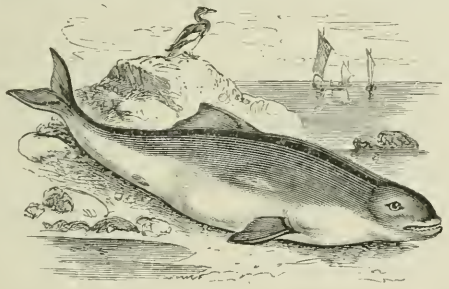
Porphyry (Gr., 'purple'), a term originally confined to an Egyptian rock used in sculpture and known as *porfido rosso antico*. It occurs as a dyke or vein some 65 to 85 feet thick in the granite of Jebel Dokhan (formerly called *Mons Porphyrites*) in Egypt, between Siout and the Red Sea. It is composed of a felspathic base, in which are disseminated crystals of oligoclase felspar, with some plates of dark hornblende, and grains of an iron oxide. The beautiful pink or red colour of the porphyritic felspar and the fine-grained base is due to the diffusion of the red variety of epidote, called Withamite or Piedmontite. The term porphyry is not now used to denote any particular rock, but is applied by architects and others to any igneous rock which, like the porfido rosso antico, has a homogeneous, compact base or fine-grained ground-mass, through which are scattered distinct crystals of one or more minerals. By geologists the term porphyry is seldom used without some descriptive word bracketed with it, as quartz-porphyry, orthoclase-porphyry, augite-porphyry, &c.

Porphyry, one of the greatest Neoplatonist philosophers, was born at Tyre, or at Batanea, in the year 233 A.D. His original name was Malchus (Heb. *Melech*, 'king'); and *Porphyrius* ('one clad in purple') is but a kind of playful synonym for this royal name. He is said by Socrates the historian and by St Augustine to have been originally a Christian; but this seems improbable, although it is certain that in his youth he was a hearer of Origen, or at least held some intercourse with him at Cæsarea in Palestine. What is more certain is that he passed at a later time to Athens, where he studied rhetoric under Longinus, the well-known author of the treatise *On the Sublime*. It was at Rome, however, whither he repaired about 263, that he found the master who permanently moulded his life. Here he became the most trusted of the disciples of the Neoplatonist

Plotinus. After a few years in Rome he went to Sicily, where, if St Jerome's account is to be relied on, he wrote his once celebrated treatise in fifteen books against the Christians, now known only from the replies—themselves lost—which it elicited from Methodius of Tyre, Eusebius of Cæsarea, and Apollinaris of Laodicea. His book itself was burned by order of the emperors Theodosius II. and Valentinian in 448. He then returned to Rome, and taught there, where he is said to have died, probably about 303. His own most famous pupil was Iamblicus. For a view of Porphyry's position in the history of the Neoplatonic school, see NEOPLATONISM. He was a very voluminous writer, and, though no very profound thinker, a learned, capable, earnest, and high-minded man. His philosophy keeps close to life and practical duties, its object the salvation of the soul, to be effected by the extinction of impure desires through strict asceticism together with knowledge of God. He was a determined opponent of Christianity, and in his trenchant criticism exposed many of its supposed errors and imperfections.

Of his writings the chief are the Lives of Plotinus and Pythagoras; *Sententiæ; De Abstinentia;* and the *Epistola ad Marcellam*, addressed to his wife. There is a complete list in Fabricius' *Bibliotheca Græca*, v., ed. Harless. See the works on the Alexandrian school by Vacherot and Jules Simon, and Zeller's *Philos. der Griechen*, vol. ii.; also the monograph by Bouillet (Paris, 1864).

Porpoise (*Phocæna*), a genus of Cetacea in the family Delphinidæ. The species are like dolphins, but have shorter snouts. The Common Porpoise (*P. communis*) is the most familiar Cetacean on the British coasts, especially to the west of Ireland and Scotland. It is found also on all the coasts of Europe from the Mediterranean



Porpoise (*Phocæna communis*).

northwards, on the coasts of North America, and in the Arctic regions. It is one of the smallest of the Cetacea, its average length not exceeding four feet, although individuals may measure six feet in length. The body is spindle-shaped, its greatest diameter being near the triangular dorsal fin. The skin is perfectly smooth, and destitute of hair. The upper surface is black with a bluish shimmer, but the under side is grayish white. There are from forty to fifty teeth in each jaw, not conical, as in most of the Cetacea, but compressed. The eye is small; the opening of the ear is very minute, like a hole made with a pin. The crescent-shaped blow-hole, with the horns of the crescent directed forwards, is situated exactly over the eyes.

The porpoise is gregarious, and large numbers are often seen together, sometimes swimming in file, when their backs, appearing above the surface of the water, suggest the idea of a great sea-serpent; sometimes gamboling in fine weather, or when a storm is approaching, or even in the midst of a storm. They feed on fish, which the teeth are admirably adapted to catch, and schools of porpoises pursue the vast shoals of herring, mackerel, &c. into bays and estuaries. They sometimes ascend rivers, apparently in pursuit of salmon, as far as the water is brackish, and are not unfrequently caught on such occasions. The skin, the oil, and the flesh are all useful. The skin is nearly an inch thick, but is planed down until it becomes translucent, and is made into excellent leather, which is used for covering carriages and for other purposes. But much 'porpoise' leather is obtained from the Beluga (q.v.), or white whale, whence come also the so-called 'porpoise laces.' Under the skin is a layer of fat, about an inch in depth, which yields oil of the finest quality. The flesh was in former times highly esteemed, and reckoned fit for the table of royalty, perhaps partly because among Roman Catholics it was accounted *fish*. In the time of Queen Elizabeth it was still used by the nobles of England, and was served up with bread-crumbs and vinegar. It is now used only in very northern regions. An entirely black Porpoise (*P. melas*) from Japan has no dorsal fin and only seventy-two teeth in all. The name porpoise is from the old French *porpeis*, from the Latin *porcus*, 'hog,' and *piscis*, 'fish,' corresponding therefore in meaning to the modern French *marsouin*, a corrupt form of the German *meerschwein* ('sea-hog').

Porpora, NICCOLA, musical composer, was born at Naples, on 19th August 1686, trained there in music, and, having produced some successful operas, was appointed master of the conservatorio of San Onofrio (1722). Shortly before that he had established a school for singing, from which came some of the greatest singers the world has known, as Farinelli, Caffarelli, Salimbeni, and Uberti. From 1725 to after 1755 he led an unsettled life, though he stayed some time at Dresden, at Venice, in London (with Farinelli, 1734–36), and in Vienna, composing music, chiefly operas (though none rises above the level of conventional respectability), and teaching singing; at Vienna he taught Haydn. Of his other musical compositions a series of cantatas (twelve published in London in 1735), several sonatas for the violin, and six fugues for the clavichord are written with considerable freshness. He died at Naples in 1766 or 1767, and now is chiefly known through George Sand's *Consuelo*.

Porridge, a highly nutritious kind of food made by boiling oatmeal in water, formerly at least one of the chief elements of diet of the Scotch peasantry. Besides oatmeal, porridge may be made of barley, beans, or the like, and instead of water milk may be used.

Porrigo. See FAVUS, and RINGWORM.

Porsena. See ETRURIA, Vol. IV. p. 446. The story of the defence of the bridge across the Tiber at Rome against Lars Porsena of Clusium in the time of Tarquin has been told in spirited verse by Macaulay in his *Lays of Ancient Rome*.

Porson, RICHARD, perhaps our greatest Greek scholar, was born on Christmas Day 1759, at East Ruston in Norfolk, where his father was parish clerk. The Rev. T. Hewitt, curate of the parish, noticing the boy's omnivorous appetite for books and his marvellous memory, had him educated along with his own sons, and brought him under the notice of a neighbouring squire, Mr Norris, the founder of the Norrisian professorship at Cambridge, who sent him to Eton in August 1774. Here he remained four years, and in 1778 was entered at Trinity College, Cambridge, mainly by the help of the physician Sir George Baker. He was elected a scholar in 1780, next year won the Craven Scholarship, and subsequently the first chancellor's medal. In 1782 he was elected a Fellow of Trinity. He now began to contribute to *Maty's Review*, his first critique being on Schutz's Æschylus, and his finest on Brunck's Aristophanes.

He also opened a correspondence with the veteran scholar David Ruhnken of Leyden. His *Notæ breves ad Toupii Emendationes in Suidam* (1790) first carried his name beyond England as a scholar of the highest rank. In 1787 appeared in the *Gentleman's Magazine* his three sarcastic letters on Hawkins' *Life of Johnson;* and during 1788 and 1789, in the same periodical, his far more famous and trenchant *Letters to Archdeacon Travis, on the Spurious Verse 1 John v. 7* (coll. 1790)—'the most acute and accurate piece of criticism since the days of Bentley,' says Gibbon. Porson naturally incurred great odium on account of the side which he took in this controversy, and it is said that one old Norwich lady, who had him in her will for a legacy of £300, cut it down to £30 when she heard that he had written a book against Christianity. In 1792 his fellowship ceased to be tenable by a layman, whereupon some friends raised a fund to preserve him from want, and about £100 a year was secured. This he accepted on condition that after his death the money should be returned to the donors, but when they refused to take it back it was used to form a foundation for the Porson prize at Cambridge. He was also appointed to the regius professorship of Greek in the university of Cambridge, an office worth £40 a year. In 1795 he edited the plays of Æschylus for the Foulis press at Glasgow, and between 1797 and 1801 four of Euripides, the *Hecuba*, the *Orestes*, the *Phœnissæ*, and the *Medea*. He also collated the Harleian MS. of the *Odyssey* for the Grenville *Homer*. He married in 1796, but his wife died five months later, too soon to cure him of his dilatory and slovenly habits and his thirst for drink. In 1806 he was appointed librarian of the newly-founded London Institution, with a salary of £200, but neglected his duties. He was suddenly struck down with apoplexy in the Strand, 19th September 1808, and died six days later. He was buried in the chapel of Trinity College, Cambridge. Porson possessed a stupendous memory, unwearied industry, great acuteness, fearless honesty, and masculine sense, but was hindered all his life by poverty, ill-health, dilatoriness, and fits of intemperance. With all his powers he achieved but little, and to justify contemporary admiration there remain, besides the works already named, but a few *bon-mots*, some brilliant emendations, the posthumous *Adversaria* (1812), and notes on Aristophanes (1820), the lexicon of Photius (1822), Pausanias (1820), and Suidas (1834). His *Tracts and Criticisms* were collected by Kidd (1815).

See 'Porsoniana' in Rogers' *Table-Talk* (1856), H. R. Luard in *Cambridge Essays* (1857), and the Rev. J. Selby Watson's *Life* (1861). His *Correspondence* was edited by Luard for the Cambridge Antiq. Soc. (1867).

Port. See STEERING; also PORT WINE.

Porta, GIAMBATTISTA DELLA, Neapolitan physicist (1543–1615), wrote numerous works on physiology, gardening, arboriculture, pneumatics, and refraction, besides several comedies; his best-known books being *Magia Naturalis* (1569) and *De Humana Physiognomonia.*—For Baccio della Porta, see BARTOLOMMEO.

Port Adelaide. See ADELAIDE.

Portadown, a market-town of Armagh, Ireland, on the Bann, 6 miles S. of Lough Neagh and 25 miles by rail SW. of Belfast. It is a place of considerable trade in agricultural produce, and manufactures linen, cambric, and sheeting. Pop. (1871) 6735; (1881) 7850.

Portage City, capital of Columbia county, Wisconsin, is at the head of navigation on the Wisconsin River, and on the ship-canal which connects it with the Fox River, 177 miles by rail NW. of Chicago. Steamboats ply to Green Bay, Lake Michigan. Portage has grain-elevators and iron-works, and manufactures leather, boots, clothing, &c. Pop. (1890) 5130.

Portage la Prairie, the market-town of a rich agricultural district in Manitoba, on the Assiniboine River, 56 miles by rail W. of Winnipeg. It has flour-mills and grain-elevators, a brewery, a biscuit-factory, a paper-mill, &c. Pop. 3600.—In North America *portage* (from Fr. *porter*, 'to carry') means a place where boats or canoes have to be carried past rapids or across between one navigable stream and another.

Portalis, JEAN ÉTIENNE MARIE (1745–1807), jurist, practised law in Paris, was imprisoned during the Revolution, but under Napoleon was chief author of the *Code Civil*. See CODE.

Portal Vein. See LIVER, CIRCULATION.

Portarlington, a market-town of Ireland, partly in King's County, partly in Queen's County, on the Barrow, 44 miles by rail SW. of Dublin. It was granted by Charles II. to the Earl of Arlington; and here William III. planted a colony of French and Flemish Protestants. Until 1885 it returned one member to parliament. Pop. 2357.

Port Arthur, the terminus of the eastern division of the Canadian Pacific Railway, on Thunder Bay, Lake Superior, 993 miles WNW. of Montreal. Pop. 5500. See OWEN SOUND.

Port Arthur, or LUSHUNKO, a naval station and arsenal on the peninsula stretching south into the Gulf of Pe-chi-li, opposite that of Wei-hai-wei, on the Shantung promontory to the south, together commanding the entrance to the gulf. The English name is derived from the captain of one of Her Majesty's ships employed in surveying the coasts of Corea and Manchuria. In the middle of the century a miserable fishing village, the port was fortified and provided with docks, electric light, a lighthouse, &c., with the help of German engineers. It was taken by the Japanese in November 1894; and in 1898 it and Ta-lien-wan, on the east coast of the peninsula, were 'leased' to Russia (nominally for 25 years, with power to extend the term). Port Arthur became a naval port closed to all but Russian and Chinese ships; part of Ta-lien-wan is similarly closed. Wei-hai-wei, taken by the Japanese in January 1895, was held by them till 1898, when it was taken over by Britain, to be held on the same conditions as Port Arthur is by Russia. The harbour is an important coaling-station, and is to be the Pacific terminus of the Trans-Siberian Railway.

Port-au-Prince, the capital of Hayti (q.v.), is situated on the west coast, at the head of a bay of the same name. Pop. 20,000.

Port Breton, in the SE. of New Ireland (now German), was in 1879 the scene of a disastrous experiment in colonising by French Legitimists under the Marquis du Rays.

Portcullis, a strong timber or iron grating sliding in the jambs of the entrance to a castle, which, when dropped to the ground, defended the gate from assailants.

Port Darwin, a magnificent landlocked deep-water harbour of the Northern Territory of South Australia. Palmerston, the chief town and port on its shores, is the terminus of the overland telegraph, 1973 miles from Adelaide, and of the cable to Java, and the starting-point of a short railway (146 miles); pop. 800.

Port D'Urban. See DURBAN.

Port Durnford, a harbour in British East Africa, a little more than 1° S. of the equator.

Porte, SUBLIME. See CONSTANTINOPLE.

Port Elizabeth, a seaport of the British colony of the Cape of Good Hope, stands on the western shore of Algoa Bay, by rail 85 miles SW. of Graham's Town and 350 S. of Kimberley. It is the principal seaport of the east part of Cape Colony, and also of the Orange River Free State. Its public buildings, solid and substantial edifices, are the town-house, the provincial hospital, churches, the Grey Institute, a college, a library (20,000 volumes), a museum, &c. There are two parks and several tree-planted squares. The town was founded in 1820, and the population, which was not much above 4000 in 1855, had grown to 13,049 in 1875, and to 23,266 in 1891. Two piers were constructed to protect the harbour in 1881; and an aqueduct, 28 miles long, has brought good water to the town since 1878. The value of the imports has increased from £376,638 in 1855 to an average of about £3,000,000; that of the exports (mainly wool, with ostrich-feathers, Angora goats' hair, and diamonds) from £584,447 in 1855 to an average of some £2,000,000.

Porteous Mob. At Pittenweem in Fife, on the night of 9th January 1736, three smugglers, Andrew Wilson of Kirkcaldy, George Robertson, an Edinburgh innkeeper, and William Hall, robbed the Kirkcaldy excise-collector of over £100. All three were at once arrested, and on 11th March were sentenced to death. In an attempt to break out of the Edinburgh Tolbooth (the 'Heart of Midlothian'), Wilson, 'a squat round man,' stuck fast in a grating, preventing also the escape of Robertson; but the following Sunday, being taken with him to hear the condemned sermon in St Giles' Church, he suddenly seized two of the four soldiers guarding them, and fastened with his teeth upon a third, at the same time crying, 'Run, Geordie, run for your life.' Robertson did get clear off; Wilson on 14th April was hanged in the Grassmarket. There was some disturbance and stone-throwing, when Captain John Porteous, the brutal commander of the City Guard, fired on the crowd, and killed or wounded sixteen or more men and women. For this he himself was tried and sentenced to death (20th July), but on 26th August was respited by Queen Caroline. However, on the night of 7th September an orderly mob burst open the tolbooth, dragged Porteous out, bore him, pleading for mercy, to the Grassmarket, and lynched him—hanged him from a dyer's pole, and slashed at him with Lochaber axes. A drunken footman of Lady Wemyss and one other man were tried next year for their share in the riot; but both were acquitted, and none of the ringleaders ever was brought to justice. A bill passed the Lords to disqualify the Lord Provost of Edinburgh from ever again holding office, to imprison him for a twelvemonth, to abolish the City Guard, to raze the Nether Port, and to fine the city in £1500 for Porteous' widow; but only the first and last clauses were carried in the Commons, and these only by a casting vote and after the fiercest opposition from all the Scotch members. Indeed, the Porteous Riot paved the way for the rebellion of the '45.

See vol. xvii. of the *State Trials* (1815); Scott's *Heart of Midlothian* (1818); and *Criminal Trials illustrative of the 'Heart of Midlothian'* (1818).

Porter, a kind of beer favoured by London porters, hence so called about 1750. See BEER, Vol. II. p. 37.

Porter, DAVID, an American naval officer, was born at Boston, Massachusetts, 1st February 1780, the son of a naval officer who fought through the Revolution. He was appointed midshipman in 1798, and lieutenant the year after; saw service against privateers in the West Indies, and against Tripoli in 1801–3; became captain in 1812, and captured the first British war-ship taken in the war. In 1813, with the *Essex* (32 guns), he nearly destroyed the English whale-fishery in the Pacific, and took possession of the Marquesas Islands; but in March 1814 his frigate was destroyed by the British in Valparaiso harbour, and Porter returned home on parole. He afterwards commanded an expedition against pirates in the West Indian waters, and was court-martialled for compelling the authorities at Porto Rico to apologise for imprisoning one of his officers. Porter resigned in 1826, and was for a time at the head of the Mexican navy. In 1829 the United States appointed him consul-general to the Barbary States, and then minister at Constantinople, where he died, 3d March 1843. Farragut, it is worth noting, was his adopted son. See the Life (1875) by his son.

DAVID DIXON PORTER, admiral of the American navy, who was born at Chester, Pennsylvania, 8th June 1813. He accompanied his father on his cruise against the pirates, and afterwards was for some time a midshipman in the Mexican service. He entered the United States navy in 1829, was employed on the coast survey from 1836 to 1841, when he became lieutenant, and then served till 1845 on the Mediterranean and Brazil stations, afterwards returning to the coast survey. From 1849 to 1853 he was engaged in command of the California mail-steamers. At the commencement of the civil war he was appointed commander of the steam-frigate *Powhatan*, and ordered to Pensacola; but afterwards he was placed in command of the mortar flotilla, joined Farragut, and in April 1862 successfully bombarded the New Orleans forts. In command of the Mississippi squadron, he assisted to bring about the fall of Vicksburg (July 1863). A rear-admiral, he bombarded and silenced Fort Fisher in December 1864. Till 1869 superintendent of the naval academy at Annapolis, he was made vice-admiral in 1866, and in 1870 succeeded Farragut as admiral of the navy. He died at Washington, 13th February 1891.

He was the author of three romances, of *Incidents and Anecdotes of the Civil War* (1885), and of a *History of the Navy in the War of the Rebellion* (1887).

Porter, ENDYMION (1587–1649), groom of the bedchamber to Charles I., whom he accompanied (with Buckingham) to Spain, and attended on the field during the Civil War—without actually fighting, it would appear. He was a patron of poets and artists, and wrote many verses. See his Life and Letters by Miss Townshend (1897).

Porter, JANE, authoress of the *Scottish Chiefs*, was born at Durham in 1776, daughter of an army-surgeon who died soon after her birth. She was brought up at Edinburgh and in London, and made a great reputation in 1803 by her high-flown romance, *Thaddeus of Warsaw*, which was distanced in its kind in 1810 by *The Scottish Chiefs*. The hero of the latter is a stilted and preposterous figure enough—as little of the historical Wallace as could well be, yet the book retains its interest for youthful readers, and had the merit of prompting Scott to complete *Waverley*. Other books were *The Pastor's Fireside* (1815), *Duke Christian of Lüneburg* (1824), *Tales Round a Winter's Hearth* (in collaboration with her sister Anna Maria, 1824), *The Field of Forty Footsteps* (1828), and *Sir Edward Seaward's Narrative of his Shipwreck and Consequent Discovery of Certain Islands in the Caribbean Sea* (1831), a clever fiction, edited by her, but almost certainly written by her eldest brother, Dr William Ogilvie Porter (cf. *Notes and Queries*, 1880). With this brother she spent some years at Bristol, and there she died, 24th May 1850.—Another brother, ROBERT KER PORTER (1775–1842),

was a clever battle-painter, and led a wandering life. He visited Russia on the emperor's commission in 1804, accompanied Sir John Moore's expedition in 1808, became knight commander of the order of Hanover in 1832, was afterwards British consul in Venezuela, and died at St Petersburg, whither his sister Jane had gone to join him, 4th May 1845. He published books of travel in Russia, Sweden, Spain, Portugal, Georgia, Persia, and Armenia.—Her younger sister, Anna Maria Porter (1780–1832), blossomed precociously into *Artless Tales* (1793–95), followed by a long series of works, among which need only be named *Octavia* (1798), *The Lake of Killarney* (1804), *The Hungarian Brothers* (1807), *The Recluse of Norway* (1814), *The Fast of St Magdalen* (1818), *Honor O'Hara* (1826), and *Barony* (1830).

Porter, Noah, philosophical writer, was born 14th December 1811, at Farmington, Connecticut, graduated at Yale in 1831, studied theology, and was for ten years a Congregational pastor. In 1846 he became professor of Moral Philosophy at Yale, and from 1871 to 1886 he was president of the college. One of the doctorates received by him was the Edinburgh LL.D. in 1886. Of his numerous works may be mentioned *The Human Intellect* (1868; often re-edited), *Books and Reading* (1870), *Sciences of Nature versus the Science of Man* (1871), *Elements of Intellectual Science* (1872), *Moral Science* (1885), *Kant's Ethics* (1886). He died 4th March 1892.

Port Erin, a port on the south-west coast of the Isle of Man, on Port Erin Bay, 5½ miles W. of Castletown, has a breakwater 950 feet long, and a steamboat pier. One mile to the north-east there is a runic monumental cross. Port Erin forms part of Rushen parish (pop. 3527).

Port Essington, an inlet in the Coburg Peninsula on the north coast of Australia, forming a fine harbour. On its shores there was from 1831 to 1850 a penal settlement.

Porteus, Beilby, was the youngest but one of nineteen children, and was born at York, 8th May 1731, his parents being both natives of Virginia. He was educated at Ripon and Christ's College, Cambridge, and graduated as tenth wrangler in 1752. He was at once made a fellow of his college, took orders in 1757, and became domestic chaplain to Archbishop Secker in 1762. His preferments were the small livings of Rucking and Witterscham in Kent (1765), which he soon exchanged for the rectory of Hunton in the same county, the rectory of Lambeth (1767), the mastership of the Hospital of St Cross, near Winchester (1769), the bishopric of Chester (1776), and of London, in succession to Dr Lowth (1787). He resigned Lambeth when made Bishop of Chester, but only gave up Hunton when appointed to the see of London. Bishop Porteus died 13th May 1809. He was a sound Churchman, yet moderate, a great enemy of profanity and Sunday concerts, and a warm friend of the West Indian slaves. He was a judicious observer of the times, as in his prudently delayed commendation of Sunday-schools. His learning was inconsiderable, and the popularity of his *Lectures on St Matthew's Gospel*, and especially his *Summary of Christian Evidences*, was solely due to the absence of better books. Porson called him 'Proteus,' and Parr described him as 'a poor paltry prelate, proud of petty popularity, and perpetually preaching to petticoats.'

See the Panegyric, rather than Life, by the Rev. Robert Hodgson (1811), editor of his works in 6 vols.; and a very full correspondence in *Notes and Queries* for 1879–81.

Port Famine, the name given by Cavendish in 1587 to a spot in Patagonia on the north coast of the Straits of Magellan. From 1843 to 1853 it was a Chilian penal colony.

Port-Glasgow, a town of Renfrewshire, on the southern shore of the Firth of Clyde, 3 miles ESE. of Greenock and 20 WNW. of Glasgow. It was founded in 1668 by the magistrates of Glasgow as a harbour for their city, the deepening of the Clyde (q.v.) not having yet been thought of. In 1710 it was constituted the head custom-house on the Clyde, and for a while took the lead of Greenock; in 1775 it was incorporated as a municipality; and by the Reform Bill of 1832 it was raised to the rank of a parliamentary burgh, uniting with Kilmarnock, &c. to return one member. Built on low alluvial ground, and backed by hills 700 feet high, it has a Doric town-house (1815), a public hall (1873), ruined Newark Castle (1597), a wet-dock of 12 acres (formed since 1834), a large graving-dock (1874), extensive timber-ponds, shipbuilding-yards, iron and brass foundries, &c. Pop. (1841) 6938; (1881) 10,802; (1891) 14,685.

Port Hamilton, a spacious, well-sheltered harbour, formed by three islands of the Nan-how group, 30 miles S. of Corea and 45 NE. of Quelpart (q.v.). It was annexed by Britain as a prospective coaling station in 1885, but abandoned in the following year. It was discovered and named by Belcher in 1845.

Port Hope, a port of entry of Ontario, on the north shore of Lake Ontario, 63 miles by rail E. of Toronto. It has a good harbour, and a trade in lumber and grain, and in the town woollens, buttons, engines, iron castings, &c. are manufactured. Pop. 5585.

Port Huron, capital of St Clair county, Michigan, is on the St Clair River where it issues from Lake Huron, and at the mouth of the Black River, 59 miles by rail NNE. of Detroit. The rivers are crossed by four iron bridges. The city has a fine custom-house (1877), shipyards and dry-docks, sawmills, grain-elevators, and machine and railroad shops. Much pine timber is brought down by the Black River. A railway tunnel passing under the St Clair River connects the town with Sarnia, in Canada (see St Clair); there is also a steam-ferry to Sarnia, and steamboats ply daily, except in winter, between Port Huron and Detroit. Pop. (1880) 8883; (1890) 13,543.

Portici, a town of Italy, on the slope of Vesuvius, 5 miles by rail SE. of Naples. Its environs are delightful, and are dotted over with country-houses. The royal palace built (1738) by Charles III. is now an agricultural college. There are a small fort, fishing, and sea-bathing. Silkworms are reared and ribbons made. Pop. 12,272.

Portioners. See Heir, Vol. V. p. 626.

Port Jervis, a town of New York, on the Delaware River, 88 miles by rail NW. of New York City. It contains railroad shops, planing and other mills, glass-works, and manufactories of boots and shoes, gloves, and watch-cases. Pop. (1880) 8678; (1890) 9327.

Portland, (1) the largest city and chief seaport of Maine, and capital of Cumberland county, on Casco Bay, 108 miles by rail NE. of Boston. It is situated on a narrow peninsula, embracing 2½ sq. m., with broad shaded streets, and handsome public and private edifices, including a court and custom-house, post-office, city hall, observatory, and Baxter and Mechanics' Halls. There are rolling-mills, and locomotives, machinery, boilers, stoves, carriages, and shoes manufactured, and sugar and petroleum refined. The harbour, which is defended by three forts, is large, deep, and well sheltered; there are wharves, elevators, and dry-docks, and an important trade is carried on; steamers ply direct to Liverpool in winter. The place was first settled by an English colony in 1632.

In 1866 a fire destroyed $10,000,000 worth of property. Portland is the seat of Episcopal and Roman Catholic bishops, and was the birthplace of Longfellow. Pop. (1870) 31,413; (1890) 36,425.—(2) PORTLAND, the metropolis of Oregon, and capital of Multnomah county, is on the Willamette River, 12 miles from where it joins the Columbia (about 100 from the ocean) and 772 by rail N. of San Francisco. It has railway communication with St Paul and Council Bluffs also, and is a prosperous port of entry, large ocean-going ships coming up to this point. A handsome city, well built, with fine, shaded streets, it has a court-house, a United States government building, numerous churches and schools, and an asylum for the insane. There are iron-foundries, machine-shops, sawmills, canneries, breweries, and manufactures of furniture, flour, shoes, &c. Clearing-house returns show $93,000,000 for 1890—exports, $12,000,000. Portland was founded in 1844, and became a city in 1851. Pop. (1870) 8293; (1880) 17,577; (1890) 46,385.

Portland. DUKES OF. See BENTINCK.

Portland, ISLE OF, a rocky peninsula of Dorsetshire, connected with the mainland by the Chesil Bank (q.v.), and 4 miles S. of Weymouth by a branch-line (1865). It is 4½ miles long, 1½ wide, 9 in circumference, and 2890 acres in area. From its highest point, the Verne (495 feet), it shelves with a gradual and almost unbroken slope to Portland Bill (26 feet), the southern extremity, where stand two lighthouses (1716–89), showing fixed lights 210 and 136 feet above sea-level, and between which and the Shambles, a dangerous reef, 3 miles south-east, a surf, called the Portland Race, is raised by the rushing of the impetuous tides. The cliffs have in places been worn into fantastic caverns; and ancient raised beaches are well marked near the Bill. Portland is one solid mass of oolitic limestone, which has been largely quarried for building purposes since the 17th century, when Inigo Jones employed it for Whitehall and Sir Christopher Wren for St Paul's. Goldsmiths' Hall, the Reform Club, and Pall Mall generally are also built of it; and the yearly export now ranges between 50,000 and 70,000 tons.

There are three different qualities of Portland stone, the three strata lying close together. The top bed, called *Roach*, is unsuited for fine hewn work, since it is full of fossils, but it is hard and durable, and does well for the walls of docks, foundations, and the like. The *Whit Bed*, which comes next, yields the best stone for fine buildings. It varies in texture from a fine close grain to the roe-like structure characteristic of oolitic limestones, and is free from shells. Its colour is a pleasing grayish white. The *Base Bed*, not quite so much quarried as the others, is of finer grain and whiter than the Whit bed; but it is softer and better suited for internal than external architectural work. An analysis of this stone by Professor Daniell shows the following composition: Silica, 1·20; carbonate of lime, 95·16; carbonate of magnesia, 1·20; iron and alumina, ·50; water and loss, 1·94; besides which ingredients there is often a trace of bitumen present. Portland stone is also quarried in the 'Isle' of Purbeck and the Vale of Wardour.

The formation of a magnificent harbour of refuge has been described at BREAKWATER, where also a map is given; most formidable fortifications have moreover been constructed, the Verne in especial being crowned by Fort Victoria. Other features of the 'Isle' are its great convict-prison, dating from 1848, and holding upwards of 1500 convicts (see PRISONS); Portland Castle (1520), built by Henry VIII., and held for Charles I. till 1646: Bow and Arrow Castle, ascribed to Rufus; and Pennsylvania Castle (1800), built by Governor Penn, the great Quaker's grandson. The inhabitants of the 'Isle' long remained a peculiar people, intermarrying, and preserving, generation after generation, the many curious customs of their forefathers. The 'Isle' itself is remarkable for its copious and excellent spring-water and for its small breed of black-faced sheep, whose flesh, well known as 'Portland mutton,' is much esteemed for its flavour. Pop. (1851) 5195; (1881) 10,061; (1891) 9541.

See Damon's *Geology of Weymouth and Portland* (1860), and an article in the *Cornhill* (1882).

Portland Beds. See JURASSIC SYSTEM.

Portland Cement. See CEMENT.

Portland Sago. See ARUM.

Portland Vase, a celebrated ancient Roman glass vase or cinerary urn found during the pontificate of Urban VIII. (1623–44) in a marble sarcophagus (of Alexander Severus, it is thought, and his mother Mammæa) in the Monte del Grano, near Rome. It was at first deposited in the Barberini Palace at Rome, and hence it is sometimes called the Barberini Vase. It was bought in 1770 by Sir William Hamilton (q.v.), and in 1787 by the Portland family, who in 1810 deposited it in the British Museum, where it is now shown in the 'Gold Room.' The ground of the Portland Vase is of dark-blue glass, and the figure-subjects which adorn it are cut in cameo style in an outer layer of opaque white glass. In the official *British Museum Guide* (1890) it is stated that the composition is supposed to represent on the obverse Thetis consenting to be the bride of Peleus, in the presence of Poseidon and Eros; on the reverse, Peleus and Thetis on Mount Pelion. On the bottom of the vase is a bust of Paris. The vase was broken to pieces by a lunatic in 1845, but the fragments were very skilfully united again. The Portland Vase is 10 inches high, and is the finest specimen of an ancient cameo cut-glass vase known. There are only two others of similar character which approach it in beauty—viz. an amphora in the Naples Museum and the Auldjo Vase. But fragments of the same kind of glass exist with work upon them quite as fine. In the end of the 18th century Josiah Wedgwood, the famous potter, made fifty copies in fine earthenware of the Portland Vase, which were originally sold at twenty-five guineas each. One of these now fetches £200.

Portland Vase.

Port Louis, the capital and principal port of the British colony of Mauritius, is situated on an excellent harbour on the north-west coast, and is enclosed by a ring of lofty hills. It is defended by forts (1887–91), is a coaling station of the British navy, and has barracks and military storehouses. There are three graving-docks beside the harbour, through which all the commerce of Mauritius (q.v.) passes. The city contains a Protestant and a Roman Catholic cathedral, a royal college, &c.; but the western part was almost wholly ruined by the hurricane of 29th April 1892. Pop. 61,170.

Port Mahon (anc. *Portus Magonis*), the capital of the island of Minorca (q.v.), is beauti-

fully situated on a deep, narrow inlet in the south-east of the island. Its harbour is one of the finest in the Mediterranean, and is protected by powerful forts and fortifications. Building stone, shoes, cottons, cattle, and honey are exported. Pop. 15,842. The town was held by the English from 1708 to 1756, and again from 1762 to 1782. It was they who made it a first-class fortress.

Port Moody. See VANCOUVER.

Porto Alegre, capital of the Brazilian state of Rio Grande do Sul, stands at the north-west extremity of the Lagôa dos Patos, by means of which it communicates with the sea. It was founded in 1742, is well built, and has about 35,000 inhabitants. It contains a cathedral, an arsenal, military and normal schools, an episcopal seminary, and a German club. Most of the wholesale trade is in the hands of the Germans, who number some 3000. Railways bring the produce of the interior down to the port, which, however, can only be entered by ships drawing 8½ feet. There are manufactories of pianos, furniture, brandy, and beer.

Portobello, a Scottish watering-place on the southern shore of the Firth of Forth, 3 miles E. of Edinburgh. Its first house (1742) was built by one of Admiral Vernon's seamen in the expedition against Puerto Bello, and hence it derived its name; but it dates, like its eastern extension Joppa, almost wholly from a time later than 1804. An esplanade, ¾ mile long, skirts the broad level sands; and there are a promenade pier of 1250 feet (1871), municipal buildings (1878), half-a-dozen churches, and manufactures of pottery, bricks, bottles, &c. Portobello, with Leith and Musselburgh, returns one member to parliament. Pop. (1841) 3587; (1891) 8682. By the Edinburgh Extension Act (1896) Portobello was incorporated with Edinburgh.

Portobelo, formerly PUERTO BELLO, a decayed seaport of Colombia, on the northern shore of the Isthmus of Panamá. It has an excellent harbour, discovered by Columbus in 1502, but has fallen into decay since 1739, when it was stormed by Admiral Vernon. Pop. 1300.

Porto Ferrajo. See ELBA.

Porto-Maurizio, a town of North Italy, stands embowered in olive-groves on the Gulf of Genoa, by rail 69 miles SW. of Genoa and 41 E. by N. of Nice, and consists of an old town on the hills and a new town next the sea, with a small harbour. Pop. 6500.—The *province* has an area of 468 sq. m. and a pop. of 145,818.

Porto Novo, a small port on the Coromandel coast of India, 145 miles S. of Madras by rail. Both the Danes and the Dutch had formerly a factory here. The place is celebrated for the battle fought here on 1st July 1781, when Sir Eyre Coote, with 8000 men, defeated Hyder Ali and an army of 60,000. From 1824 on for some years there was an iron-foundry here, the ore being brought from Salem. Pop. 7823.

Porto Rico, or PUERTO RICO, a West India island (Spanish till 1898), lies 75 miles E. of Hayti or St Domingo. An oblong in shape, it has an area of 3530 sq. m., about five-sixths the area of Jamaica, and measures 110 miles from east to west, and 40 from north to south. It is traversed from east to west by ranges of mountains, 1500 feet in average height, though Mount El Yunque rises to 3670 feet. From the base of the mountains rich alluvial tracts extend to the sea on all sides, and are watered by innumerable short streams. The higher parts are covered with forests. Rain falls in much greater abundance on the north than on the south of the island. The principal crops are sugar, coffee, and rice (the food of the people), though tobacco, maize, yams, bananas, plantains, and tropical fruits are also grown. Large herds of cattle and horses are fed on the lowland pastures. The imports consist of cotton and woollen goods, metals and hardware, and provisions, as rice, flour, ale, fruits, &c., and reach a value between two and three millions sterling; they are supplied principally by Great Britain, the United States, and Spain in nearly equal proportions. The exports are sugar, coffee, molasses, tobacco, and cattle, valued at two to two and a half millions, from three-quarters to one and a quarter million being for sugar and the same value for coffee. Spain and the United States are the chief customers; France and Great Britain come next. The population increases rapidly: in 1800 it was 155,400; in 1834, 358,800; in 1864, 615,844; in 1880, 754,313 (429,473 being white); and in 1898, 820,000. Chief towns are St John's (q.v.), the capital, and Ponce (38,000). Porto Rico was discovered by Columbus in 1493; Ponce de Leon founded a settlement in 1510. A rising against Spain in 1820–23 failed; Porto Rico was ceded to the United States as a result of the war (1898), and in 1900 an act of congress conferred civil government on the island.

Portpatrick, a decayed fishing-village in Wigtownshire, 7¾ miles SW. of Stranraer by rail. It is sheltered by high cliffs, and has a pleasant south-westerly exposure, but the coast is rocky and the sea boisterous, while there are no facilities for bathing, although the village enjoys some reputation as a watering-place. Portpatrick is but 21½ miles direct north-east of Donaghadee in County Down, was long the Gretna Green for Ireland, and the chief place for the importation into Scotland of Irish cattle and horses, while it was a mail-packet station from 1662 till 1849. A pier was built in 1774, and a great artificial harbour was commenced from Rennie's designs in 1821, but ultimately was found impracticable as a place of shelter owing to the violence of the south-westerly swell and the winds that blow for eight months of the year. The public confidence in the harbour received its death-blow from the wreck of the *Orion* steamship within the port in 1850, when about seventy souls perished within a few yards of the crowded street. The lighthouse was removed in 1869, and the harbour-works fell quickly into hopeless ruin, after having cost the country £500,000. Pop. of parish (1831) 2239; (1891) 1219.

Port Phillip, the gate of Melbourne, discovered in 1802 by Lieutenant Murray, and named in honour of Captain Phillip, the first governor of New South Wales (q.v.). Victoria itself was originally called the district of Port Phillip.

Portraits. COMPOSITE, a method of indicating the facial characteristics of a family or group of persons, while at the same time suppressing the peculiarities of individual members. Mr Francis Galton has thus prepared type faces each composed of a number of individuals specially celebrated for some particular branch of art, science, or occupation. The results are recognised as of considerable value to the student of anthropology.

One way of obtaining these composite portraits is to take full-face photographs of each person composing the group, of such a uniform size that two fixed horizontal lines pass, one through the inner angle of the eyes, the other through the line dividing the lips, while a third fixed perpendicular line equally divides the nose; by this means the photographs are brought approximately to the same size, and corresponding portions of the various faces occupy similar positions. Now suppose there are ten individuals in the group, and that any one negative would require half an hour to produce a good print, then each negative is printed for one-tenth of half

an hour, and is carefully adjusted so that each succeeding negative occupies the same position on the print as the preceding one; thus a composite portrait will result, each of the ten likenesses having an equal share in its production. Where any characteristic is common to all or several, that peculiarity will be more or less pronounced; where, however, only one or two persons possess a peculiarity, it is scarcely, if at all, noticeable. By taking a negative of a succession of positives a composite negative will result capable of indefinite reproduction. The result is often a highly idealised portrait representative of the family, or of the poet, statesman, mathematician, gaol-bird, &c., and typical of the group it represents.

Portree. See SKYE.

Portreeve, once the English name of the principal magistrate in a port town, especially in London (q.v.).

Port Royal. See JAMAICA.

Port-Royal des Champs, a convent of Cistercian nuns, nearly 8 miles SW. of Versailles, which obtained much celebrity during the 17th century. It was founded for nuns by a member of the family of Montmorency in the early part of the 13th century, and soon after its establishment obtained from the pope the privilege of receiving lay persons, who, without taking monastic vows, desired to live in religious retirement. The discipline of the convent having been much relaxed in the 15th and 16th centuries, one of its worst abuses—that of appointing the superior, not on account of fitness, but from considerations of family or other worldly or political motives—became in the end the occasion of its complete reformation under Marie Angélique Arnauld (q.v.). The community was removed to Paris in 1626, and in 1633 to a new convent, Port-Royal de Paris; and from this time the old establishment of Port-Royal des Champs was exclusively devoted to the use of a lay community. This community soon numbered among its permanent inmates some of the most distinguished scholars of that age, Antony Arnauld, Le Maistre, Antony and Louis Isaac le Maistre de Sacy, Nicole, Lancelot, Séricourt, and others. Their rule of life was most austere, rising at 3 A.M., devoting many hours to prayer and spiritual reading and instruction, and a portion of the day to manual labour. One of their public services was the establishment of a school, for which they prepared well-known educational books, the Port-Royal Greek and Latin Grammars, General Grammar, Geometry, Art of Thinking ('Port-Royal Logic,' new ed. by Professor Spencer Baynes, 1881), &c. But Port-Royal is best known for its adhesion to the Jansenist movement (see JANSEN). The nuns of Port-Royal having refused to subscribe the formulary condemning the Five Propositions, a royal order was issued in 1660 for the suppression of the school and the removal of the boarders of Port-Royal des Champs; and the abbess and several other nuns were arrested, and confined as prisoners in other monasteries. After the 'Peace of Clement IX.' they were permitted to return; but the two communities were placed under separate government. When the final steps for the repression of the Jansenist party were taken about 1707 a formal bull was issued by Pope Clement XI. for the suppression of Port-Royal des Champs, and the transfer of its property to Port-Royal de Paris. The nuns were finally dispersed and distributed over convents of different orders throughout France. The property of the convent and church was transferred to the Paris house, and all the buildings of Port-Royal des Champs were levelled to the ground by order of the king. See Sainte-Beuve, *Port-Royal* (4th ed. 6 vols. 1878); Charles Beard, *Port-Royal* (2 vols. 1861).

Portrush, a watering-place in County Antrim, 6½ miles by rail N. of Coleraine, and 7 W. by S. of the Giants' Causeway, with which it is connected by an electric tramway (1883). The town is built on the isthmus of a short peninsula, looking to the Causeway cliffs on the one side, and to Inishowen and almost Malin Head on the other. It has fine stretches of firm sand for bathing, and has communications by steamer with Morecambe and Glasgow. Pop. 1322.

Port Said, a town of Egypt, on the west side of the Suez Canal, on a desolate strip of land between Lake Menzaleh and the Mediterranean. The place owes its origin to the Suez Canal (q.v.), being named after Said Pasha, its promoter, and depends wholly on the canal trade, mainly as a coaling-station. Pop. (1882) 16,560; (1897) 42,095.

Portsea Island, a small island on the south coast of Hampshire, has on its west side Portsmouth Harbour and on its east side Langston Harbour, and is separated from the mainland on the north by a narrow channel, crossed by several bridges. It is four miles long by from two to three broad, and contains the towns of Portsea and Portsmouth.

Portsmouth, the chief naval arsenal of Great Britain, and an important seaport, market-town, and municipal, parliamentary, and county borough, in the south of Hampshire, stands on the south-west shore of Portsea Island (q.v.), at the entrance to Portsmouth Harbour, and opposite the town of Gosport (q.v.), with which it communicates by means of a steam-bridge. It is 74 miles SW. of London, 44 W. of Brighton, and 23 SE. of Southampton. Besides the parish of Portsmouth, the limits of the municipal and parliamentary borough, which are co-extensive, include also the parish and town of Portsea, and the out-wards Landport and Southsea, and comprise the whole of Portsea Island, with the exception of a small portion in the north-east corner. Pop. of the borough (1821) 69,479; (1851) 72,096; (1871) 113,569; (1881) 127,989; (1891) 159,255. Portsmouth is for the most part a mean-looking, dirty town, but has the most complete fortifications in Britain. These comprise, on the landward side, the outer line of the Portsdown forts and the Hilsea lines; to seaward, the Spithead (q.v.) forts. A portion of the bastioned ramparts, which formerly encircled both Portsmouth and Gosport, and were so imposing in appearance, have since 1872 been removed as useless. Southsea, which is situated outside the walls skirting Southsea Common, is rapidly increasing, and is now a fashionable watering-place. In the town proper there are few objects of note. Pleasing views may be had from the ramparts and batteries, of the harbour, the roadstead of Spithead, and the Isle of Wight. Many improvements have been carried out in Portsmouth, including improved drainage, and the opening of the Victoria Park in 1878; also a new town-hall has been built at a cost of £140,000, which was opened by the Prince of Wales in 1890. Among the few notable buildings may be mentioned the church of St Thomas, whose chancel and transept date from the close of the 12th century, the nave and tower from 1698, and which contains a ghastly cenotaph in memory of the murdered Duke of Buckingham. The Garrison Chapel, Early English in style, and finely restored by Street in 1867, is a fragment of the hospital of St Nicholas, founded in 1212 by Bishop Peter de Repibus. In it Charles II. married Catharine of Braganza; and in front of it is buried the brave Sir Charles James Napier (q.v.), who died in this neighbourhood in 1853. The dockyard of Portsmouth, in the district of Portsea, was till 1872 only 116 acres in extent; but vast

works have since then been carried out at a cost of £2,500,000, which have increased the area to a total of 293 acres. Of this immense naval establishment the most noteworthy, if not the most recent, features are the mast and rope houses, hemp-stores, rigging-stores, sail-loft, and the dry-docks, spacious enough to admit the largest vessels, and offering every facility for their speedy repair. The twelve docks, 22 to 36 feet deep, are lined with solid masonry, roofed over, and closed by lock-gates. Of the various building-slips, one of them, roofed and covered in, is so large that three or four vessels can be in process of construction under it at the same time. The Wood Mills contain a number of most ingenious block-making machines, the invention of Sir Isambard Brunel (q.v.), in which rough timber, introduced at one end, is cut, squared, drilled, bored, and turned into the required shape. About 150,000 blocks are made here annually, and the machines require the attendance of no more than four men. In the smithy anchors are forged by aid of a Nasmyth's hammer.

The dockyard also contains the residences of the superintending officers, and a school of naval architecture.

Portsmouth Harbour, about 400 yards wide at its entrance, expands into a spacious basin, extending inland for about 4 miles, and having a breadth of 3 miles along its northern shore. Large war-vessels can enter and lie at anchor at all times of the tide, there being 4 fathoms of water in the channel at low water. The outward entrance is defended by Forts Monckton and Gilkicker, and Southsea Castle. The position of this harbour is highly favourable. It is situated in the middle of the channel, close to the magnificent anchorage of Spithead, where 1000 ships of the line may ride without inconvenience, and is under shelter of the Isle of Wight, and opposite the French arsenal of Cherbourg.

The local trade of Portsmouth is chiefly supported by the dockyard and other public establishments. Brewing is largely carried on. Coals, potatoes, corn, and timber are imported from British coasts, and potatoes, granite, corn, timber, cattle, and wine from abroad. The only exports are pottery (shipped at Fareham) and coal-tar pitch.

The importance of this port dates only from the reign of Henry VIII. Its defences were commenced by Edward IV. and strengthened by Elizabeth, and afterwards in a more thorough manner by William III. Here, in a house that still remains in the High Street, and which was then an inn called the 'Spotted Dog,' the Duke of Buckingham (the 'Steenie' of King James) was assassinated by John Felton. On the 29th of August 1782, when its commander, Admiral Kempenfeldt, was writing in his cabin, the *Royal George* went down at Spithead, and nearly 1000 lives were lost. Charles Dickens was born at 387 Mile End Terrace, Commercial Road, Landport, Portsea; and other worthies of Portsmouth have been Walter Besant, the younger Brunel, Jonas Hanway, Sir Frederick Madden, George Meredith, and John Pounds.

See L. Allen's *History of Portsmouth* (1817), H. Slight's *Chronicles of Portsmouth* (1828), H. P. Wright's *Story of the 'Domus Dei' or Garrison Church* (1873), W. H. Saunders' *Annals of Portsmouth* (1880), and Murrell and East's *Extracts from Portsmouth Records* (1884).

Portsmouth, (1) the metropolis and only seaport of New Hampshire, is on the south bank of the Piscataqua River, 3 miles from the Atlantic, and 57 miles by rail NNE. of Boston. Built on a beautiful peninsula, overlooking a capacious and deep harbour, with smooth rock bottom, it is a handsome old town, many of its streets lined with shade-trees, and is a favourite summer-resort. It has a custom-house, and some shipbuilding is still carried on; the manufactures include cotton, hosiery, shoes, iron-castings, and beer. At Kittery, on an island opposite, is a United States navy-yard, with large ship-houses and a floating balance-dock, 350 feet long by 105 wide, with twenty-four pumps. Portsmouth was settled in 1623, and was capital of the state till 1807. Pop. (1890) 9827.—(2) Capital of Scioto county, Ohio, stands among hills in an iron region, on the Ohio River, at the mouth of the Scioto, and at the south terminus of the Ohio Canal, 106 miles by rail ESE. of Cincinnati. It has several iron-foundries, rolling-mills, stone-mills, and sawmills, and manufactures stoves, nails, steel springs, furniture, machinery, boots, &c. Pop. (1890) 12,394.—(3) A city and port of Virginia, capital of Norfolk county, on the Elizabeth River, opposite Norfolk. Gosport, with its navy-yard, &c. (see NORFOLK), is a suburb. Portsmouth contains a dry-dock and a naval hospital, and exports naval stores, iron, lumber, cotton, and early vegetables for the north. Pop. (1890) 13,268.

Portsmouth, DUCHESS OF. See CHARLES II.

Port Townsend, capital of Jefferson county, Washington, is on Puget Sound, near Juan de Fuca Strait, 47 miles N. of Seattle. It has a good harbour, and an important United States customs station, at which all vessels entering or leaving the sound must report. Pop. (1880) 917; (1890) 4498.

Portugal, a kingdom of Europe, on the west side of the Iberian Peninsula, stretches 350 miles between 36° 59′ and 42° 8′ N. lat., and varies in width from 70 to 140 miles between 6° 10′ and 9° 31′ W. long. Its eastern and northern boundaries are Spain, its western and southern the Atlantic

Ocean. Details of provincial areas and populations are given in the subjoined table.

Province.	Area in sq. m.	Pop. (1890).
Minho	2807	1,091,936
Traz os Montes	4293	416,980
Beira	9248	1,450,441
Estremadura	6876	1,083,290
Alemtejo	9431	388,813
Algarve	1873	228,635
Azores	1005	255,594
Madeira	505	134,040
Total	36,038	5,049,729

The population increases steadily but slowly: in 1851 it numbered 3,487,000; in 1874, 4,160,315; and in 1881, 4,708,178. But fully 16,500 persons emigrate every year, the majority going to America, chiefly to Brazil.

Physical Aspects.—In respect of its physical structure and conformation, Portugal forms an integral part of the Iberian Peninsula (see SPAIN). The coast is low and flat, and sandy, except for one or two short distances, as immediately north and south of the mouth of the Tagus, and at Cape St Vincent in the extreme south-west. The two northern provinces are diversified by spurs (5000 feet) of the mountains of Spanish Galicia. The most important mountain-range of Portugal is the Sierra da Estrella (6540 feet), a westward continuation of the Spanish Sierra Guadarrama system. The Sierra Morena is continued westwards in southern Portugal. In like manner, the principal rivers of the country—the Guadiana in the south, the Tagus in the centre, and the Douro and Minho in the north—are simply the lower courses of what are geographically Spanish rivers. The Mondego, which reaches the sea about half-way between the Tagus mouth and that of the Douro, is the longest river that has its sources in the country. Portugal has numerous mineral springs, a large proportion being impregnated with sulphur. Minerals exist in fairly rich abundance, but are not worked to the extent they could be, chiefly from want of fuel and cheap means of transit. Salt is prepared in large quantities in the salt marshes; copper, iron, lead, manganese, antimony, gypsum, lime, and marble are extracted and in part exported. About 5500 persons in all are engaged in mining, the yield of which reaches the total value of £224,000 per annum.

Climate.—The vicinity to the ocean tempers the climate of Portugal, and exempts it from the dry heat by which Spain is visited. The inequalities of the surface produce, however, diversities of climate; for, while snow falls abundantly on the mountains in the northern provinces, it is never seen in the lowlands of the southern districts, where spring begins with the new year and harvest is over by midsummer. Rain falls abundantly all the year round, especially on the coast, and from October to March. As a general rule, the climate is healthy in the elevated districts, even of the southern provinces; but malaria and fever prevail in the low flat lands and near the salt marshes. The mean annual temperature ranges from 60° F. at Oporto to 63°·5 at Lagos on the south coast.

The animal life and plant life do not differ from those of Spain (q.v.).

Occupations.—The soil is generally rich, except in the mountainous parts; but agriculture is everywhere in a backward state, little more than half the area of the country being put to profitable use. Arable land occupies only 15½ per cent.; grass-land, 24 per cent.; orchards, 7 per cent.; forest, 3 per cent.; vineyards, 2⅛; and olive-groves, about the same extent. The cereals chiefly grown are maize; wheat, rye, barley, and rice, but not in sufficient quantity for the wants of the people. Potatoes, vegetables (especially onions), flax, fruits (oranges, lemons, chestnuts, almonds, &c.) are grown in large quantities. But the cultivation of the vine and of the olive are the most prosperous branches of industry; from the former is derived the rich red wine familiarly known as Port, from its being shipped at *O Porto*, 'the port.' The total quantity of wine annually produced in Portugal amounts to 88,000,000 gallons. Cattle are reared in the north, sheep and goats in the centre, and swine in the oak forests of the south. In the vine districts of the north and centre the soil is mostly owned by peasant proprietors; in other parts of the country great estates are owned by the nobles and let to tenants to cultivate. The rearing of silkworms and the keeping of bees are pursued with some energy. Fish is abundant in all the rivers and off the coasts. Tunny and sardines are exported; and of late attention has been given to the rearing of oysters.

Commerce, &c.—Portugal is not a manufacturing country; what industry there is is principally concentrated in the two chief towns, Lisbon and Oporto. In all, some 91,000 persons are engaged in industrial pursuits, and of these nearly 40,000 are employed in weaving wool. The rest cut cork, manufacture cotton, linen, silk, leather, glass and porcelain, paper, and gold and silver filigree, and carry on various other industries. In 1889 the mercantile marine of Portugal comprised 443 vessels (43 steam), measuring in all 77,906 tons. During the four years ending 1887 the Portuguese ports were entered by an average of 5565 ocean-going vessels of 3,404,500 tons, but in 1893 by 5873 of 5,793,000 tons; of these totals, nearly half in number and more than half in tonnage were British. In 1893, 1450 miles of railway were open, and 300 more in course of construction. The exports, consisting principally of wine, copper, salt, cork, fish, oxen, fruits, vegetables, and wool, average 5½ millions sterling in value annually. More than one-half of this total is for wine, the actual value ranging between £1,580,200 (in 1879) and £3,751,770 (in 1886). Of this again the greater part is for port wine, exported to Britain, 3 to 4 million gallons annually, valued at 1 to 1¼ million sterling; and to Brazil, to an annual average of £608,000. France takes every year about £868,000 worth of the common wine of the country. The value of all the exports sent to Great Britain every year ranges from 2⅓ to nearly 4 millions sterling. Apart from wine, the principal items are cork, copper, live oxen, and wool. From Great Britain Portugal imports chiefly cottons (½ to ¾ million sterling), woollens, coal, metals, machinery, and butter, to the annual value of 1¾ to 2½ millions sterling. Her total imports, which, in addition to the articles mentioned, embrace bullion, flour and wheat (more than £1,000,000 annually), glass, live-stock, silk, timber, linen, &c., reached the value of 11¼ millions in 1889, a steady increase from 7¼ millions in 1885. Germany, France, and the United States rank next after Great Britain as sources whence Portugal draws her imports.

Finance.—In spite of her commercial prosperity, Portugal cuts a bad figure in her financial arrangements. For years there has been an annual deficit, which is mostly met by loans, so that the national debt is rapidly increasing. Whereas in 1878 the national income was £5,673,000, the expenditure was £7,629,500; ten years later the income had increased to £8,468,000, but the expenditure was £10,000,000. The national debt has increased from £20,974,000 in 1856 to £64,333,000 in 1871, and £148,490,103 in 1893, besides £4,784,777 of floating debt. The interest for the country's loans is accordingly some £5,000,000, by a long way the heaviest item in the national expenditure.

Defence.—Every Portuguese above twenty-one

years of age is liable for service in the army. Twelve years is the period of service, three years with the colours and nine in the reserve. On the peace footing the army embraces in all about 33,000 men; the war strength is about 150,000 men of all arms. The fleet consists of 1 ironclad, 10 corvettes and screw-steamers, 21 gunboats and transports, 5 torpedo boats, 13 sailing-vessels, and 7 training and coastguard ships, the whole manned by 2850 sailors and 250 officers.

Religion, Education.—The state religion is that of the Church of Rome, but toleration is extended to all other creeds. There are three ecclesiastical provinces presided over by the Cardinal Patriarch of Lisbon, the Archbishop of Braga, who is primate of the kingdom, and the Archbishop of Evora; these dignitaries rule over fourteen bishops. The monasteries were dissolved in 1834, their properties, yielding about one million sterling annually, being appropriated by the state. Education is superintended by a council, at the head of which is the minister of the Interior, and is entirely free from the supervision and control of the church. Compulsory education was enacted in 1844, but is far from being fully enforced, consequently Portugal lags behind in education and general intelligence. There are nearly 4000 elementary schools, with 180,000 pupils; 22 lyceums, with 8260 pupils; numerous private schools; polytechnic academies at Lisbon and Oporto; and clerical, medical, agricultural, naval, and military training-schools. The one university at Coimbra (1300), one of the oldest in Europe, has five faculties, 75 professors, and about 900 students. Schools for training in the industrial arts are in great favour; there are 28 in the country, headed by larger institutes at Lisbon and Oporto. Lisbon has a learned society (the Academy of Sciences), and a public library (1796) of 200,000 volumes. There are other libraries at Coimbra (1591), with 84,000 vols., and at Oporto (1833), with 100,000 vols.

Constitution.—Portugal is a constitutional monarchy, the crown being hereditary alike in the female and the male line. The parliament, or *Cortes*, consists of the House of Peers and the House of Deputies. By a law of 1885 the former will, when the necessary changes have been made, eventually consist of one hundred life members elected by the king and fifty elected indirectly, five by the university and scientific societies and forty-five by popular electors. The House of Deputies consists of 149 members, elected directly by all citizens above twenty-one years of age who possess certain qualifications of property or status. Parliaments are elected every four years; sessions last three months in the year. The deputies are paid 11s. a day. The executive is wielded by a cabinet of seven ministers, chosen by the premier (one of the seven), who himself is selected by the king. The departments are Interior, Justice, Public Works, Finance, Marine and Colonies, War, and Foreign Affairs. The sovereign also consults a council of state, of not more than sixteen members, nominated for life, and generally including ex-ministers and present ministers. Justice is administered by rural magistrates in 146 district courts, in 3 courts of appeal (at Oporto, Lisbon, and Azores), and in the supreme tribunal of the kingdom at Lisbon.

People.—The Portuguese are a mixed race—originally Iberian or Basque, with later Celtic admixture. Galician blood (derived from the ancient Gallaici, presumably Gallic invaders) predominates in the north; Jewish and Arabic blood are strongly present in the centre, and African in the south. The Portuguese differ essentially from their Spanish brethren, whom they regard with inveterate hatred and jealousy, mainly on account of their past attempts to subvert the independence of Portugal. The opinions of observers differ as to the national traits of the people. They seem, however, to be generally sober, good-natured, obliging, and patriotic, but shiftless and dirty. Both Lisbon and Oporto have a population exceeding 100,000; no other town reaches 30,000. Lisbon is the capital, Oporto the centre of the port-wine trade, and the chief town of northern Portugal.

The colonial possessions of Portugal are enumerated in the subjoined list:

	Area in sq. m.	Pop.
AFRICA—		
Cape Verde Islands	1,486	110,926
Senegambia (Guinea)	26	5,945
St Thomas and Prince's Island	417	21,000
Ajuda (fort, Guinea Coast)	13½	700
Angola, Ambriz, Benguela, Mossamedes, and Congo	312,000	2,000,000
Mozambique	(?)80,000	(?)600,000
ASIA—		
Goa (in India)	1,262	445,450
Diu, Daman, &c.	102	55,313
Timor	6,290	300,000
Macao (in China)	4½	70,000
Total	401,601	3,609,334

HISTORY.—Romans followed Carthaginians as conquerors (138 B.C.) of the western Iberians and Celts. Under Augustus the peninsula was divided into three provinces, one of which, Lusitania, has, until quite recent times, been regarded as nearly identical with the present kingdom of Portugal; but the Augustan province of Lusitania lay wholly on the south side of the Tagus. The history of Portugal was in early times coincident with that of the Iberian Peninsula as a whole; and, along with the rest of the peninsula, Portugal was thoroughly Romanised in the days of the empire. After the Romans withdrew, the peninsula was overrun by Visigoths from the north, and at a later period by Saracens from the south. Under Roman, Visigothic, and Saracenic rule the people were prosperous and well governed, but became enervated by luxury and unwarlike ease. About the middle of the 11th century northern Portugal fell under the sway of Ferdinand I. of Castile. In 1094 Henry of Burgundy, who had married a natural daughter of Alfonso VI., son and successor of Ferdinand, received from that monarch the county of Portugal (from the Minho to the Tagus) as a dependent fief. Under his widow, Theresa (1114–28) the country acquired a sense of national unity and a certain measure of independence. Their son, Alfonso I., made Portugal an independent kingdom (1143)—through the victory of a picked body of Portuguese knights over a picked body of Castilian knights in a tournament—and gained signal advantages over the Arabs, whom he fought for twenty-five years, his greatest exploits being the victory in the plain of Ourique, in Alemtejo, in 1139, the capture (with the help of English crusaders) of Lisbon in 1147, and of Alcacer do Sal in 1158. The Burgundian House, which continued in possession of the throne for 440 years, gave to Portugal some of its best kings. The immediate successors of Alfonso I. were engaged in incessant wars against the Moslems and in severe struggles with the clergy and nobles, who were always ready to combine against the sovereign; but, although often baffled in their attempts to uphold the independence of the crown, the dignity of the kingdom was, on the whole, well maintained by the representatives of this family, who were, moreover, distinguished as

the promoters and champions of the maritime glory of Portugal. Sancho (died 1211), the 'builder of cities,' especially distinguished himself by his care for the material welfare of his kingdom, and by his bold fight against the claims of Pope Innocent III. and that pope's supporters, the Portuguese bishops. His son, Alfonso II., summoned the first Portuguese Cortes. Alfonso III. (1248–79) conquered the southern province of the kingdom in 1250, and made Portugal what it practically is in area at the present time. His son Diniz (Denis) must be regarded as the founder of Portuguese commerce and mercantile enterprise. He likewise encouraged agriculture and the industrial arts, and protected learning, in furtherance of which he founded in 1300 a university at Lisbon, subsequently transferred to Coimbra. Diniz was succeeded in 1325 by his son, Alfonso IV., surnamed the Brave, whose reign was almost wholly occupied in wars with the Castilians and the Moslems (see CASTRO, INEZ DE). It was during his reign that the friendly commercial relations with England began. With Alfonso's grandson, Ferdinand I., the legitimate branch of the Burgundian House became extinct in 1383. After some disturbances Ferdinand's illegitimate brother, John, was recognised by the Cortes as king in 1385; four months later the allied Portuguese and English army won at Aljubarrota a glorious victory over the Castilians, who had invaded the country. John's reign (he died in 1433) was eventful, not merely on account of the internal reforms which he introduced, and of his steady maintenance of the prerogatives of the crown, but chiefly as being associated with the first of those important geographical discoveries and commercial enterprises which made Portugal for a while the greatest maritime power of Europe. During this reign, on May 9, 1386, the treaty of Windsor cemented the firm alliance and national friendship between Portugal and England, that was further confirmed by the marriage of King John to the daughter of John of Gaunt (1387). To John's son, Henry the Navigator (died 1460), is due the merit of having organised several voyages of discovery, which culminated in the acquisition of the Azores, Madeira, Cape de Verde, and other islands. At this time, too, the slave-trade began, the Portuguese bringing captive negroes to cultivate the large estates of their southern provinces. During the reign of John II. (1481–95), who broke the power of the feudal nobles, Bartholomeo Diaz doubled (1486) the Cape of Good Hope: and Vasco da Gama, in the reign of John's successor, Manoel, successfully achieved the passage by sea to India in 1497. The discovery of Brazil (1500), and the settlements made there and on the western coast of India by Albuquerque (q.v.), increased the maritime power and fame of Portugal, which were further extended under Manoel's son, John III., who ascended the throne in 1521.

At this period Portugal ranked as one of the most powerful monarchies in Europe, and Lisbon, the great distributing centre of the products of the East, as one of its most important commercial cities. Sudden as this prosperity had been, its decline was almost more abrupt, and may in a great measure be accounted for by the destruction of the old nobility, the extensive emigration that went on to the new colonies, the expulsion of the numerous wealthy and industrious Jews, on whose able financial management the commercial interests of the Portuguese were largely dependent, and the introduction of the Inquisition (1536), and of the Jesuits (1540), whose baneful supremacy gave rise to much tyranny and oppression, both in the colonies and at home, and in various ways stamped out the old spirit of the people, and crippled the resources of the nation. The influence of the Jesuits over John's grandson, Sebastian (1557), was responsible for the defeat of the Portuguese, and the capture and death of their young king, at the battle of Alcazar al-Kebir in Africa in 1578. And the extinction of the old Burgundian line in 1580, after the brief reign of Sebastian's uncle, Cardinal Henry, plunged the country into difficulties and misfortunes. After a struggle for the throne between half-a-dozen candidates, none of whom found favour with the nation at large—they clung to the delusive hope that Sebastian was still alive, and would return from the hands of his Moorish captors—Philip II. of Spain succeeded in securing to himself the crown of Portugal and annexing the kingdom to the Spanish monarchy. This involved it in the ruinous wars of Spain against England, in the Low Countries, and in Germany, while the Dutch and English, in retaliation for Spanish aggressions at home, attacked and seized the Portuguese possessions in the Indian Archipelago and in South America. At length the insolence of Philip IV.'s minister, Olivarez, brought matters to a crisis; and in December 1640, after a forced union of sixty years, Portugal was freed, by a bold and successful rising of the nobles, from all connection with Spain, and the Duke of Braganza, a descendant of the old royal family, was placed on the throne (1641), under the title of John IV. The war with Spain, which was the natural result of this act, turned out, under the guidance of the famous Count Schomberg (who fell at Boyne battle, 1690), and with the assistance of 3000 English troops, favourable to Portugal, and was terminated in 1668 by the treaty of Lisbon, by which the independence of Portugal was formally recognised by the Spanish government. But her ancient glory had departed; she had lost many of her colonies, and of those she still retained Brazil alone was prosperous; the nation was steeped in ignorance and bigotry; and the Portuguese, from having been one of the greatest maritime powers of Europe became virtually a commercial dependent, rather than ally, of Great Britain, especially after the Methuen (q.v.) Treaty of 1703. Under the reign of Joseph I. (1750–77) the genius and resolution of the minister Pombal (q.v.) infused temporary vigour into the administration, and checked for a time the downward tendency of the national credit. But Pombal's efforts to rouse the people from their sloth, and infuse vigour into the government, were checked by the accession of Joseph's daughter, Maria, who, with her uncle-husband, Pedro III., allowed things to turn back into their old channels. The mental alienation of Maria led, in 1799, to the nomination of a regency under her eldest son, John. This prince, who showed considerable capacity in early life, on the outbreak of the war between Spain and France threw himself wholly on the protection of England; and finally, when he learned that Napoleon had determined on the destruction of his dynasty, left Portugal in 1807 and transferred the seat of government to Rio de Janeiro, the capital of Brazil (q.v.).

This act was immediately followed by the occupation and annexation of Portugal by the French—a measure which gave rise to the Peninsular War (q.v.). The victory of Vimeira, gained by the combined English and Portuguese army in 1808, freed the land from its French assailants; and in 1816, on the death of Queen Maria, the regent succeeded to the joint crowns of Portugal and Brazil. But even after the French were driven out of the Peninsula and Napoleon's power was broken for ever, the new king, John VI., still continued to reside at Rio de Janeiro, leaving Portugal to be governed by English officers, Marshal Beresford and others. This gave occasion to abuses and discontent, which resulted, in 1820, in a revolution at Lisbon, and in the proclamation of a constitutional form of

government, very democratic in spirit, in the place of the pre-existing feudal absolutism. John hurried to Portugal, and there signed the constitution and ratified the independence of Brazil, which proclaimed his son Pedro emperor. On the death of John in 1826, Pedro IV., after organising the government of Portugal on the model of the English parliamentary system, renounced the Portuguese crown in favour of his daughter, Maria da Gloria, a child of seven, on condition that she married her uncle, Miguel. The latter, who had availed himself of every opportunity to thwart the liberal policy of his father and brother, waited only for the embarkation of the English troops to break the oath which he had taken to maintain the constitution, and, gathering round him the clergy, the army officers, the old nobility, and all who were in favour of the former order of things, was through their aid declared king by the Cortes in June 1828.

Then ensued a period of indescribable confusion and misrule. At length, in 1832, Pedro was enabled, chiefly by means of a loan from Englishmen, to raise an army, and make a landing at Oporto. Charles Napier virtually destroyed Miguel's fleet off Cape St Vincent in 1833. Shortly afterwards Queen Maria made her entry into Lisbon; and in the following year Miguel signed the Convention of Evora, by which he renounced all pretensions to the throne, and agreed to quit Portugal. The death of Pedro in the same year, after he had effected several important reforms, including the reintroduction of the constitution of 1826, proved a heavy misfortune to Portugal, which suffered severely from the mercenary rule of those who occupied places of trust about the person of the young queen. Her marriage, in 1835, with Augustus, Duke of Leuchtenberg, and, after his death at the end of a few months, her marriage with Ferdinand of Saxe-Coburg, were followed by grave political disturbances. A branch of the democrats, known as the Septembrists, from the month in which they made their first decisive stand against the government, loudly demanded (1836) the abrogation of the charter promulgated by Pedro (known as the Charter of 1826), and the restoration of the democratic constitution of 1824. This contest of the charters continued through the entire reign of Maria, and party feeling ran so high that it resulted more than once in hostilities. The government was alternately in the hands of Septembrists and Chartists; one Cortes was dissolved after another; finally, in 1852, a revised charter was drawn up that proved acceptable to all parties. Shortly afterwards the queen died, and her eldest son ascended the throne in 1853 as Pedro V., under the regency of his father. The latter used his power discreetly; and by his judicious management the financial confusions and embarrassments were partially removed. Upon the sudden death of Pedro in 1861 his brother was proclaimed king as Luis I. He steadily adhered to constitutional principles, and laboured at measures of internal improvement; but ever since the beginning of the century the royal power has been growing weaker and weaker. The financial condition of the country has also gone steadily from bad to worse, in spite of fairly favourable commerce. The rush of the European powers to appropriate African soil, and divide it amongst them, since the opening of the interior through the Congo, in some degree awoke the old colonial enterprise of the Portuguese, and touched their national pride, making them cling all the more tenaciously to the fragments of colonial territory still left to them in Africa. But the awakening came too late; the march of events and the energy of her rivals have wrested from her many square miles that she claimed as her own, but had done next to nothing to colonise and develop. England in the end of 1889 compelled Portugal to abandon her claims to Nyassaland, and two years later a treaty was signed defining the respective spheres of influence of the two countries in East and West Africa, especially in the basin of the Zambesi. Further delimitations were agreed upon in 1891. In the meantime Charles I. had succeeded his father, October 1889. The action of Britain occasioned an outburst of strong popular feeling in Portugal, which the republicans turned to their own advantage; and they were greatly helped by the successful revolution of the republicans in Brazil and the expulsion of the emperor (November 1889). But in the home country their advantage proved to be of only a temporary nature.

H. Major, *Life of Prince Henry of Portugal* (1868); and Carnota, *Memoirs of Saldanha* (1880); Salisbury, *Portugal and its People* (1893).

Language and Literature. — Portuguese, like every other branch of the Romance family of languages, has grown out of a local form of the *Lingua Romana Rustica*, and in course of time has had ingrafted upon it many elements of Arabic from the Saracen invaders, and numerous verbal and idiomatic characteristics of the Frankish and Celtic dialects which were introduced with the Burgundian founders of the monarchy. The earlier forms of Portuguese bore close affinity to Galician; and, although Portuguese presented strong resemblance to its sister-language, the Castilian, in so far as both possessed numerous words of identical origin, it differed so widely from the latter in regard to grammatical structure as almost to merit the designation of an original tongue. The antipathy existing between the Portuguese and Spaniards, and the consequent strenuous efforts of the best writers among the former to keep their language distinct, and to resist the introduction of further Castilian elements, had the effect of making Portuguese still more dissimilar from the sister-tongues of the peninsula, and the result has been a language that differs from pure Spanish in having an excess of nasal sounds and fewer gutturals, with a softening or lisping of the consonants, and a deepening of the vowels, which renders it the softest, but feeblest, of all the Romance tongues. The earliest specimens of genuine Portuguese belong to the beginning of the 13th century, and consist for the most part of collections or books of song (see Cancionero), which, both in regard to form and rhythm, resemble the troubadour or *minne* songs of the same period. Amongst the writers of these the most outstanding figure is King Diniz, who, besides being the forerunner of the Portuguese school of pastoral poets, also drew inspiration from the popular songs of his people. In the 14th and 15th centuries, whilst the romances of chivalry were popular and numerous chronicles were written, the best being that of Fernan Lopes (1380–1459), the court continued to be the centre of poetry and art; but Castilian was in greater vogue than Portuguese, which was despised by the numerous royal poets who emulated the example of Diniz, and composed love-songs and moral or didactic poems. Under the culture of these noble bards the poetry of Portugal was weak and effeminate, without the tenderness and pathos which characterised the Spanish verse 'romances' of that age. But the literature of Portugal acquired new vigour

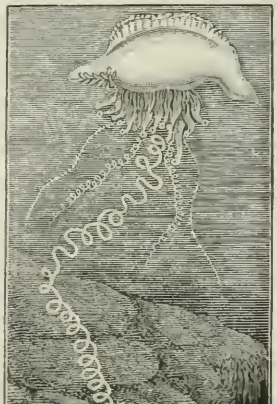
with the growth of her maritime and commercial prosperity. The *Cancioneiro Geral* (1516) of Garcia de Resende (1470–1554), which gives a general summary and extracts of the Portuguese poets of the later half of the 15th and beginning of the 16th century, is the first evidence of the change, which is most strongly exemplified in the dramas of Gil Vicente (1470–1536), and in the pastorals and eclogues of Ribeiro (*c.* 1500) and Sá de Miranda (1495–1558; q.v.), whose dramatic imitations of Horace and Terence mark the transition period between the mediæval lyrical and the later classical style. These first attempts at the drama were followed by Antonio de Ferreira's (1528-69) *Ignez de Castro*, the oldest, and still the finest, Portuguese tragedy. But the classical school, whose chief cultivators were the courtiers of Lisbon and the professors of Coimbra, found little favour among the people at large, whose enthusiasm and patriotism were deeply stirred by the discoveries and conquests of the nation in Asia, Africa, and America. The national pride and glory found expression in the works of Portugal's one really great poet, Camoens (1524–80; q.v.), who, in *The Lusiads* (1572), struck out a new path in the domain of epic poetry; while his numerous sonnets, his songs, his dramas, and other poetic productions exhibit a versatility of genius and graceful tenderness which place him in the foremost rank of European poets. Next after Camoens come the epic poets Côrte-Real (1540–93), Mousinho de Quebedo, F. de Andrade (1540–1614), Pereira de Castro (1571–1632), and Sá de Menezes (died 1664). To the same period belongs the dramatist Ferreira de Vasconcellos (died 1585).

With Camoens the language and poetry of Portugal reached the culminating point of their development. During the dominion of Spain the Portuguese so far lost all feeling of national independence that they at length renounced their native tongue, and adopted the language of their rulers. With the restoration of political independence, under the sway of the House of Braganza, a reaction took place; but the 17th and 18th centuries produced few Portuguese writers who attained more than an ephemeral and purely local reputation—bombast, or slavish imitation of Spanish and Italian writers, being the predominant characteristics of the Portuguese school of light literature. Some good historical writers belong, however, to this period, as Jacinto Freire de Andrade (1597–1657), whose life of Joao de Castro, Viceroy of India, still holds its place as a monument of classical Portuguese prose; the great Indian missionary, the Jesuit Father Antonio Vieira (1608–97), whose sermons and letters are regarded as models of style and diction; De Barros (1496–1570), the historian of *The Conquest of the Indies;* Da Faria e Sousa (1590–1649), De Brito (1569–1617), and Brandão (1584–1637), who wrote *Monarchia Lusitana;* A. de Resende (1498–1573); and F. X. de Menezes (1673–1743). During the 18th century French literary canons and models were slavishly followed by most Portuguese writers of verse, of whom the best known is Da Cruz e Silva (1731–1800). But in the beginning of the 19th century Portuguese poetry was partially elevated from its previous low grade by two men, who, although they professed to observe a strictly classical style, possessed a delicacy of taste, and a genial creative power, which saved them from falling into the absurdities that had generally characterised the school in Portugal. The elder of these, F. M. do Nascimento (1734–1819), although specially noted as an elegant lyric poet, deserves notice for his graceful miscellanies; while Manoel du Bocage (1766–1806), his less cultivated rival and contemporary, must be regarded as the most original and truly national of the modern poets of Portugal. His sonnets rank as the finest in the language, and these, with his numerous idylls, epigrams, and occasional poems, composed in various styles and modes of versification, have had a host of imitators, among the best of whom are the dramatist, J. B. Gomes (died 1803); De Macedo (1761–1831), the epic poet; and the satirist, T. da Almeida (1741–1811). The best of the recent Portuguese poets are A. de Castilho (1800–75) and D'Almeida Garrett (1799–1854). The last named was the most versatile and popular writer of his time in Portugal. Next to them come Herculano (1810–79), who is also one of Portugal's best historians; Da Silva Mendes Leal; De Lemos, founder of the Coimbra school; Palmeirim, De Passos, De Deus, Braga, and Do Quental. Other modern writers who deserve mention are the historians Da Luz Soriano and Latino Coelho; Branco and Biester, playwrights; the novelists Rebello da Silva (who ranks after Herculano as a scientific historian) and De Queiroz; and Lobo (1763–1844), as a general man of letters.—Portuguese literature is also cultivated in Brazil, and, of late years, with considerable independence and success. The principal names in poetry are F. V. Barboza, De Barros, Da Cunha Barboza, A. T. de Macedo, Gonçalves Diaz, Porto-Alegre, M. de Macedo, Teixeira e Souza, and Magelhaens, the most national of them all; in history, Varnhagen, author of the *Historia Geral de Brazil*, and P. da Silva, author of the *Brazilian Plutarch;* and the epigrammatist Fonseca.

See T. Braga's *Historia da Litteratura Portugueza* (14 vols. 1870–80), his *Curso* (1886) and his *Antologia* (1876); F. da Silva and Acanha's *Diccionario Bibliografico Portuguez* (12 vols. 1858–85); Bouterwek, *History of Spanish and Portuguese Literature* (Lond. 1823); and French works by P. da Silva (1866) and Loiseau (1885).

Portugalete, a Spanish seaport 8 miles NW. of Bilbao, with a lofty swing-ferry; pop. 3500.

Portuguese Man-of-War (*Physalia*), a remarkable genus in the class Cœlenterata, in the sub-class Siphonophora. It is common in tropical seas, floating on the surface with an inflated brightly coloured bladder, sometimes 6 inches in length, and with a pendent colony of individuals, among which there is no little division of labour. Most important are the nutritive and reproductive members, and long stinging tentacles which stream for several feet into the water. The stinging power, normally used in benumbing the small animals on which the floating colony feeds, is sufficient to cause intense irritation in those who incautiously test it. The Physalia floats for the most part passively, and is occasionally driven to British coasts. An allied genus, Rhizophysa, is even more remarkable, with a large float and long stem.



Physalia utriculus.

Portulaceæ, or PORTULACACEÆ, a natural order of exogenous plants, nearly allied to Caryophyllaceæ. The species are not very numerous;

they are much diffused over the world, and are shrubby or herbaceous, generally succulent, mostly growing in dry places. The flowers are often large and beautiful, but ephemeral. The foliage is bland and insipid. Some species are used as salads and pot-herbs, of which the best known is Purslane (q.v.). The tuberous roots of *Claytonia tuberosa*, a Siberian plant, are used for food. The genera Calandrinia and Portulaca furnish some beautiful annuals.

Port Wine (i.e. *Porto* or *Oporto Wine*), a species of red wine, hot and heady, which is produced chiefly in a mountainous district of Portugal, called Cima de Douro, and exported from Oporto and Lisbon. The vine from which this wine is produced is generally planted on craggy slopes with a southern exposure. The wine, when pure and unadulterated (which is very seldom the case), does not acquire its full strength and flavour till it has stood for some years, to allow for the disturbance of the spirit to subside, and the antagonistic ingredients of the mixture to harmonise; but care must likewise be taken that it is not allowed to become too old. The colour of new port wine varies from pale rose to deep red, and changes with age, becoming a deep tawny brown, which is permanent. By far the greater portion of the wine made is mixed with spirit even during the time of fermentation, in order to give the new wine the ripeness and strength which exporters require, and which the wine does not naturally attain till it has stood for some time; the proper colour is also given by a mixture known as *jeropiga*, which is a preparation of elder-berries, molasses, raisin-juice, and spirit. It is an excess of this jeropiga in the inferior sorts of port which communicates to them the medicated odour so frequently noticed. The extreme 'headiness' of port is chiefly due to the liberal admixture with spirit, and this is the case with all the sorts generally exported, which average 35 per cent. of proof spirit. From the time when port came into demand (about 1700, though it was known in England for a considerable time before this) down to 1826 its export was a monopoly in the hands of the English merchants; and the amount of wine produced increased, with tolerable steadiness, year after year, till the three years ending 1840, when it reached 34,790 pipes of 126 gallons. The ultimate effect of this monopoly of the Oporto Wine Company was to increase the price of port wine in England, and at the same time so to deteriorate its quality that in course of time it became of less demand, and was largely supplanted by southern French and other wines. Since that period it has fluctuated, being sometimes more and sometimes less than this figure; in 1850 the exportation reached 37,487 pipes. Between 1880 and 1895 the exports to Great Britain ranged from 3,000,000 to 4,000,000 gallons (not all for consumption in that country), and the value from £900,000 to £1,340,000. The *natural* port wine, with less than 26 per cent. of proof spirit, is very wholesome and invigorating. The exports of port wine from Oporto in 1880 were 55,700 pipes, valued at £1,471,000, but in the years 1880–97 decreased considerably on the whole.

Poscidon. See NEPTUNE.

Posen (Polish *Poznan*), a province of Prussia, bounded N. by West Prussia, E. by Poland, S. by Silesia, and W. by Brandenburg. Area, 11,178 sq. m. The Warthe traverses it from east to west, and is navigable throughout the greater part of its course, as is also the smaller Netze. The Vistula touches Posen on the north-east. The province belongs to the great plain of north Germany; there are several lakes in the east. Like Pomerania, it is essentially an agricultural province, nearly 62 per cent. of the area being arable land, 13 per cent. meadows, and 20 under wood. More than 55 per cent. of the total is in the hands of large landed proprietors (see also MECKLENBURG). Grain, potatoes, and hops are the principal products. The industry is not much developed, being limited chiefly to machinery, cloth, bricks, sugar, and beer. Pop. (1891) 1,751,642, of whom over 880,000 are Poles, mostly in the rural districts, 725,000 Germans, principally in the towns, and 51,000 Jews. There is a Roman Catholic archbishop of Gnesen and Posen. The chief towns are Posen (the capital), Gnesen, Bromberg, Lissa, and Rawitsch. Posen formed an integral part of Poland till 1772, when, at the first partition, the districts north of the Netze were given to Prussia; to these were added in 1793 Great Poland, except Masovia, the whole being incorporated under the name of South Prussia. In 1807 Posen was included in the duchy of Warsaw; but by the Congress of Vienna it was re-assigned to Prussia under the title of the Grand-duchy of Posen. In 1848 the Poles gave the Prussian government considerable trouble. See History by Chr. Meyer (1881).

POSEN, the chief town of the province, and a fortress of the first rank (1827–53), is situated on the Warthe, 158 miles by rail E. of Berlin. One of the most ancient cities of Poland, it became the seat of a Christian bishop in 968, and it was the capital of the early Polish dukes. In the 16th century it was an important trading mart, but by the end of the same century had begun to decline. Recent improvements have rendered it one of the pleasantest towns in Prussia; it has regularly built streets and squares and handsome suburbs. The fortifications have been strengthened by detached forts built in 1876–84. The cathedral, a Gothic pile dating from 1775, has attached to it the 'Golden Chapel' of Count Raczynski, which is adorned with valuable treasures and works of art. The principal secular buildings are the town-house (1508), containing valuable archives; the Raczynski Palace, with a library; the Dzialynski Palace, with archives; and the archiepiscopal palace. There is a provincial museum of antiquities. The chief manufactures are artificial manures, agricultural implements, furniture, carriages, &c.; and there are likewise several breweries, distilleries, and flour-mills. Pop. (1875) 60,998; (1890) 69,627, about one-half being Poles, the other half Germans, though the Jews number nearly 7000. See Histories by Lukaszewicz (1881) and Öhlschläger (1866).

Posidonia. See PÆSTUM.

Posidonius, a Stoic philosopher, born at Apamea, in Syria, about 135 B.C., who studied at Athens, and settled at Rhodes, whence in 86 he was sent as envoy to Rome. Here he became intimate with Cicero, Pompey, and other conspicuous Romans. He died at the age of eighty-four, leaving works on philosophy, astronomy, and history, of which only fragments have been preserved.

Posilipo (from a villa here called *Pausilypon*, 'Sans-souci,' which at one time belonged to the Emperor Augustus), a mountain on the north-west of Naples, close by the city, from of old a noble site for the villas of wealthy citizens. It is remarkable for the tunnel known as the Grotto of Posilipo, through which the road from Naples to Pozzuoli (anc. *Puteoli*) passes. The grotto varies in height from 20 feet to 80 or more, is 20 to 30 feet wide, and 755 yards long. It is traditionally said to have been made in the reign of Augustus, but is probably earlier. Above the eastern archway of the grotto is the so-called

'Tomb of Virgil.' At the base of the hill anciently stood the poet's villa. During the middle ages the common people believed the grotto to be the work of the poet, whom they regarded as a great magician. Two other tunnels penetrate through the hill, one to the north of the grotto, 800 yards long, 39 feet high, and 33 feet broad, made for the tramway, and another constructed at the command of Agrippa in 37 B.C., but only discovered in 1812.

Positivism, the System of Thought and Life founded by Auguste Comte (1798–1857; q.v.), is defined by him as consisting essentially of a 'philosophy and a polity which can never be dissevered; the former being the basis, and the latter the end, of one comprehensive system, in which our intellectual faculties and our social sympathies are brought into close correlation with each other.' He chose the word *Positive* on the ground of its indicating the *reality* and *constructive tendency* which he claimed for the doctrine in its theoretical aspect, while he anticipated that in the future the term would acquire a wider meaning by suggesting also similar ideas in the sphere of feeling and action. The two primary characters of Positivism, the philosophy and the polity, were finally welded into a whole under the conception of a religion, which has for its creed the new synthesis established by the one, and for its practice the scheme of moral and social reorganisation proposed by the other. We may best consider Positivism under these three aspects.

Positive Philosophy.—Comte's primary aim was to put an end to the intellectual and social anarchy which had resulted from the destructive criticism and the revolutionary upheaval of the 18th century, by supplying an interpretation of phenomena which should organise our knowledge of the world, of man, of society, into a consistent whole. Such a universal synthesis must the new philosophy provide to form a sure basis for a new art of life.

Historical analysis revealed to Comte, as a law of mental growth, the progress of all human conceptions through three distinct phases. The primitive stage he called the *theological;* the transition stage, the *metaphysical;* and the final stage, the *positive.* The meanings which he attaches to these words are most concisely explained by Stuart Mill's translation of them into volitional, abstractional, experiential. The transition was effected by the gradual acceptance of the scientific method of induction from observation of phenomena as the only sound basis of explanation, all inquiry into causes other than phenomenal being finally given up as fruitless. Science, therefore, is the instrument capable of effecting the desired unity; and the problem of the positive philosophy is a threefold one: (1) to bring all knowledge within the sphere of scientific investigation; (2) to extend scientific methods through the whole territory of each division; (3) to co-ordinate the results obtained from the separate sciences, so as to approach an expression of all our knowledge in terms of a single doctrine. All three parts of this problem Comte considered to be in a large degree solved by his *Classification of the Sciences.*

He observed that the several classes of conceptions advanced from the theological to the positive stage with different degrees of facility, and on inquiring into the law of progression he found that the order of emancipation of the various sciences was determined by the degree of complexity and the consequent relations of dependence. A preliminary distinction was made between the abstract and the concrete sciences, the former treating separately of the general laws manifested by all the phenomena of any class, and the latter depending on these and treating of definite objects under the several aspects in which they may be viewed. The concrete sciences, Comte considered, did not yet admit of co-ordination, and he confined his classification to the abstract sciences, which he placed in the following series: (1) Mathematics; (2) Astronomy; (3) Physics; (4) Chemistry; (5) Biology; each of these drawing its data from the preceding science, and adding a new order of conceptions peculiar to itself. This series he found coincident with the sphere of knowledge then supposed to admit of scientific treatment. But there remained the phenomena of human character and society, forming a wide field of inquiry to which positive methods had never yet been applied. Certain tentative efforts had indeed been made to construct a so-called science of history—notably by Montesquieu and Condorcet—but no one before Comte had formulated the principles on which such a task might be accomplished. By his discovery of the methods proper to a rational study of social phenomena, and by his dicta—that owing to the complexity of the conditions involved, the laws of such phenomena cannot be determined *a priori*, but must be inductively observed, and afterwards verified and co-ordinated by deductive application of the general laws of life; that the statical condition of each historical period must be viewed in its totality, as determined by the interaction of the various classes of social factors; that intellectual evolution affords the true measure of social progress—by his enunciation of these and other doctrines Sociology was created and established in the hierarchy as the last and crowning science of the series.

The whole realm of fact was now included in the domain of positive inquiry, and Comte next addressed himself to the task of rationalising the separate departments of knowledge. In the earlier portion of this task his mathematical aptitude ensured him a large measure of success; while in biology he paved the way for further developments by his organisation of the materials then available. His main services, however, in scientific co-ordination were in the department of sociology. Besides the formal constitution which he gave to the new science, his chief substantive contribution was his enunciation of the fundamental law of intellectual development, already referred to as the cardinal doctrine of the positive philosophy. The progress of thought, moreover, from theological to positive conceptions was shown to be coincident with a progression in social action from an aggressive militarism, through a period of defensive attitude, to the final régime of industrialism. The two series of transitions are mutually dependent, our increasing knowledge of the conditions of our existence and our systematic efforts to modify them naturally reacting on each other.

The main problem of the positive philosophy, the unification of knowledge, was not yet ripe for its final solution in the days of Comte, but his classification of the sciences is regarded by his followers as affording an admirable framework for the theory of evolution advanced at a later date with the claim of supplying this want. Comte was fain to be content with the demonstration of a subjective unity in the subservience of all the sciences to the needs of man.

Positive Polity.—On the basis of the philosophy he had thus established Comte founded a scheme of individual and social conduct. The ethical portion he did not live to complete, but in his elaborate exposition of the art of social politics we have ample insight into his views on what he considered an integral part of his system. We have space here only for a bare outline.

The most complete life must be that which rests on the fullest knowledge. We naturally strive to improve those conditions of our existence which we can affect in the direction indicated by the clearer

light of a new synthesis. What, then, are the evils or imperfections of our lot which may be remedied by applying positive philosophy to life? Cosmical laws are wholly beyond our direct influence, and we can only to a limited extent affect the conditions of their action. But in the science of man we ourselves are the factors, and our efforts to modify our environment form the subjective aspect of what is, objectively considered, a law of social development.

Comte believed the first requisite of systematic action to be the recognition of a central intellectual and moral authority dissociated from practical politics, which he proposed to secure by organising a *Spiritual Power*, consisting of philosophers, supported by the state. This class, exerting a purely *moral* control, yet supreme in all affairs of private and social life in virtue of its natural prestige, would have only an indirect influence on political action. The temporal power should be in the hands of capitalists, the captains of industry—chosen by their own order and naming their successors—who would feel a moral responsibility to the spiritual power, especially when the authority of the thinkers should be strengthened by the support of women and of the working-classes, whose ready adherence to positive principles Comte firmly anticipated. Besides the corrective influence of each of these powers on the other, an efficient check on despotic control on the part of either is provided in the perfect freedom of opinion and expression allowed—a freedom the more valuable that it would rest on a system of scientific and moral education, which it would be one of the chief functions of the spiritual power to direct and enforce.

With the decline of militarism and the growth of industrialism Comte foresaw that political action would in the future be mainly directed on the organisation of labour for the benefit of society at large. No idleness would be permitted; all would be workers. The distinction between the capitalists and the workmen, the rich and the relatively poor, would remain; but the former would be taught to hold their wealth and power as in trust from society to be used for the benefit of all, while the latter would also come to regard themselves as performing public functions, serving society each in his place. These views are substantially similar to such more recent economic teaching as that of Carlyle and Ruskin in Great Britain.

In the sphere of morals the main office of the spiritual power would be to strengthen the social tendencies of man at the expense of the personal, a process made possible by the development of the affections originally called forth in family life. In the sphere of intellect it should regulate and concentrate the labours of its members, putting an end to the present 'dispersive speciality' of scientific aims, and determining the direction of all intellectual efforts by reference to social needs. In pursuance of the constructive principle of Positivism Comte applies these general doctrines to the immediate future, by propounding a scheme of concerted action for a great Western Republic, embracing the French, English, German, Italian, and Spanish nations—an organisation imperfectly effected by the influence of Feudalism and Christianity.

Positivist Religion.—Such are the creed and the practice of Positivism. But a religion is more than creed and practice; there must be a sentiment, an appeal to the heart, a satisfaction of the feelings. The conception of an object of love and reverence proposed by Comte to succeed the idea of a Deity (whose existence he considered it impossible either to affirm or deny) is that of *Humanity*, regarded as a collective unity, a *great being*, consisting of all the men and women past, present, and to come, whose lives have been or shall be devoted to the well-being and progress of the race. This being, partly ideal yet wholly real, capable of being definitely conceived, and not beyond the reach of our services, would gather round it all our affections for our fellow-men; gratitude and reverence for those whose struggles and achievements in the past have made us what we are; love and sympathy for all around us who are striving after better things; hope and effort for the more perfect life of those yet unborn. Comte looked on the religion of Humanity as fulfilling all the highest aims sought by the religions of the past, and especially as succeeding naturally to Christianity, the historical value of which he thoroughly appreciated as a transitional phase of religious development. The worship of Humanity was to consist in prayer, taking the form of high resolve strengthened by effort after ideal communion with the noble spirits among the dead; and in public commemorations, for the observance of which a calendar was suggested, associating each day of the year with some great name in the roll of mankind, and arranged so as to illustrate the course of human progress. The spiritual power would carry on the traditions of the priesthoods of former religions, preaching self-abnegation as the rule of life that brings the highest happiness, and offering no reward, save a place in the 'choir invisible' of the great and good, whose names are cherished in the hearts of those who follow them, and whose influence will live to the end of time.

Positivism is of too recent origin to be adequately treated except in an account of its genesis, and the above outline of the system has therefore been entirely confined to the works of its founder. In his lifetime Comte attached to himself a body of disciples more remarkable for intellectual eminence than for numbers. The most prominent of these was M. Littré (q.v.), who afterwards edited his master's works, and established a review with the title of *La Philosophie Positive*. His discipleship, however, did not extend to the later developments of the system. Near the end of his life Comte founded the Positivist Society, an organisation which still has its headquarters in Paris; but it has extended to most other countries, and the number of adherents increases slowly but steadily. The *Revue Occidentale*, their organ in the press, is published quarterly in Paris. Among the best known of the English Positivists are Dr Congreve, Mr Frederic Harrison, Dr Bridges, and Professor Beesly, who have translated Comte's chief works and have published many expository and illustrative papers and addresses. There are two centres of Positivist activity in London, each with connections in other large towns. One of these, which is presided over by Dr Congreve, has introduced more of a ritual into its services; while the best-known group, associated chiefly with the name of Mr Frederic Harrison, and having its headquarters at Newton Hall, Fetter Lane, devotes itself mainly to extending a knowledge of the system by public addresses and various forms of practical effort.

Among sympathetic critics of Positivism are many thinkers of eminence imbued with the positive spirit, and more or less indebted to the genius of Comte. Stuart Mill, in his work on *Auguste Comte and Positivism* (1865), though taking an independent standpoint, speaks in terms of high appreciation not only of the leading doctrines of the positive philosophy, but also of the conception of humanity as a *Grand Être*, which is the keystone of the new religion. Many of the details of ritual and worship, however, were repugnant to him, as they have proved to many; and, while exaggerating the importance of these, he makes an arbitrary separation between the earlier and the later portions of Comte's career. His book should be read along with Dr Bridges' reply, entitled *The Unity of Comte's Life and Doctrines* (1866). Mr Herbert Spencer has taken more pains to vindicate his independence of Comte than to acknowledge his obligation to him. His references to his great predecessor mostly concern their disagreements. In

two essays, one on *The Genesis of Science* and the other on *The Classification of the Sciences*, he opposes Comte's views on these subjects; and he has even thought it necessary to publish an article entitled *Reasons for dissenting from the Philosophy of M. Comte*. Mr Spencer's exposition of the theory of evolution is regarded by Positivists as a valuable contribution to that scientific philosophy the inauguration of which they claim for their master. G. H. Lewes, in the chapter on Comte in his *History of Philosophy*, calls him the greatest thinker of modern times, and declares himself an ardent adherent of the positive philosophy. For the religious aspects of Positivism, however, Lewes' feeling is one of partial sympathy only. In George Eliot's works the influence of Comte's doctrines is evident, and she has devoted one of her poems to the interpretation of the Positivist conception of immortality. In addition to the works of these writers, the following are the most important criticisms of Positivism, representing various degrees of sympathy and antagonism: John Morley, article 'Comte' in *Ency. Brit.*; Professor Edward Caird, *Social Philosophy and Religion of Comte*; Dr J. M'Cosh, *Christianity and Positivism*; Dr Martineau, in *Types of Ethical Theory*; Professor Huxley, 'Scientific Aspects of Positivism,' in *Lay Sermons*; and Mr A. J. Balfour, *Religion of Humanity*.

Among critics wholly antagonistic to Positivism are naturally to be found the theologians and so-called metaphysicians—i.e. all whose explanations of phenomena either assume the action of supernatural beings or are expressed in terms of abstractions such as *vital principle, inherent tendency, nature*. Such thinkers, Positivists contend, generally profess little knowledge of scientific fact; but with these may be included many scientific specialists whose contracted view of the phenomenal world unfits them for general conceptions, and leaves them open to theological and metaphysical influences beyond the immediate sphere of their own specialty. The opposition of these classes follows from the refusal of Positivism to recognise the claims of such modes of thought to other than an historical importance.

Posse Comitatus ('the *posse* of the county'—the infinitive 'to be able' being used in late Latin as a noun, and meaning power or force), the whole force of the county, consisting of knights and men above the age of fifteen, with constables, who attend the orders of the sheriff to assist in enforcing process or quelling riots. Justices of the peace can also, if apprehensive of an organised resistance, command the services of the posse comitatus, and it is the sheriff's duty to raise the necessary number of men. But practically, in modern times, constables and special constables are all the assistance given or required. See SHERIFF.

Possession is the relation which subsists between a person and a thing, when the person has control over the thing, and maintains his control with the intention of exercising rights over the thing. A man may be in possession of what is not his own; a thief enters into unlawful possession of another's goods; a farmer has lawful possession of his landlord's property. Again, a man may own a thing without possessing it, and the law prescribes the forms of action, &c. whereby an owner may recover possession of his property. In a reasonably well-governed community possession is evidence of right to possess; the person in possession is therefore protected against all the world, unless there is some other person who can show that he has a better title: this is what is meant by saying 'possession is nine points of the law.' We speak sometimes of an interest in possession, as distinguished from an interest in reversion or remainder: thus, the person who is entitled to receive the rent of land has an interest or estate in possession, though he does not possess the land. In common speech possession is frequently used as synonymous with property; but for legal purposes the two ideas must be carefully distinguished. See Hunter's *Roman Law*; and Pollock and Wright's *Essay on Possession in the Common Law* (1888). There may be joint-ownership in either personal or real property, one of the characteristics of this kind of ownership being 'benefit of survivorship'—i.e. if one of the joint-owners dies his interest accrues to the other, and does not go to the deceased co-owner's heirs and representatives. In partnership, when one partner dies his share belongs to his own personal representatives.

Possession. DEMONIAC. See DEMONOLOGY, EXORCISM.

Posset, a dietetic preparation, made by curdling milk with some acidulous liquor, such as wine, ale, or vinegar. White wine or sherry is usually preferred, but sometimes old ale is used. The milk is boiled, and whilst it is still on the fire the acidulous matter is added; if sherry, about a wineglassful and a half to the pint of new milk is the proportion, or twice the quantity if ale. A teaspoonful of vinegar or of lemon-juice is sometimes used instead; one or two tablespoonfuls of treacle may be added, to sweeten. Taken at bedtime, it is used for colds and coughs.

Post-captain. See CAPTAIN (NAVAL).

Postglacial and Recent System. The deposits belonging to this system contain the remains of plants and animals, few of which are not still existing species. The beds consist of more or less incoherent and unconsolidated materials, which have been formed under very diverse conditions. They are represented by the low-lying alluvial flats that occupy the sites of silted-up lakes, and the bottoms of valleys at moderate elevations above the streams and rivers. Most of the bogs of northern and central Europe belong to the same system, but some had commenced to form towards the close of the glacial period. Many bogs overlie the remains of old forests, and not infrequently trees, occupying the place of growth, occur in the peat at various levels. Two such 'buried forests' have been met with in the bogs over a wide region in north-western Europe. At many places on the coasts of the British Islands and the opposite shores of the Continent peat with buried trees passes out to sea, and has been dredged up from the sea-bottom at considerable distances from the land. The only other formations that need be mentioned are the raised Beaches (q.v.) which are met with at various heights above the present sea-level, and the local moraines and fluvio-glacial gravels of the higher valleys of the Scottish Highlands. Some of these moraines come down to the level of the 45 to 50 feet beach.

The flora and fauna of the period are essentially the same as at present. In the earlier stages of the period, however, the flora of north Germany, Denmark, southern Sweden, &c. was arctic-alpine, and that flora was accompanied by the northern mammals, including the reindeer, &c. Later in the period, as the climate became more genial, the northern flora and fauna disappeared from the low grounds of temperate Europe, and the present plants and animals took their place. Of the more notable mammals of the period in Britain were *Megaceros* (Irish deer), *Bos primigenius*, and *Bos longifrons*. The oldest traces of man met with at this stage belong to the Neolithic phase.

Several geographical and climatic changes appear to have supervened in postglacial and recent times. After the Scandinavian flora and fauna had been succeeded in our area by the present assemblage of plants and animals, the climate appears to have become even more genial than it is in our day. Great forests spread far north into regions where trees do not now grow, and reached elevations on the mountains which they cannot now attain. At the same time many southern types of molluscs

migrated into northern seas, some of which have since died out, or still survive in diminished numbers and dwarfed in size. To this genial stage belong the great oaks and other leafy trees in the lower buried forests of the bogs. Eventually the climate changed and became wet and cold. The British area, formerly continental, was insulated and of less extent than now—the sea overflowing the low ground of Scotland up to a height of 45 to 50 feet above its present level. Local glaciers then made their appearance in many mountain-glens, and even descended in some places to the sea. The 'carse-clays' (45–50 feet terrace) belong to this stage. The climate was not so favourable for the growth of great trees, which were now more restricted in their vertical and horizontal range. Over wide areas the forests decayed and became buried by mosses and their allies. The general occurrence throughout north-western Europe of a second well-marked 'buried forest' seems to indicate a return to more genial climatic conditions, giving rise to a second period of great forests, which gradually overspread much of the moory and waste lands. Coincident with this second forest-epoch there appears to have been a gain of land, at least in Scotland, but there is no evidence to show that Britain again became continental. The second forest-epoch was succeeded as the first had been by somewhat cold and wet conditions, under the influence of which the forests decayed, while swamps and morasses increased. At the same time the Scottish area became depressed for some 25 feet or thereabout below its present level. The last physical change of which there is clear evidence is the final retreat of the sea, while the general aspect of the bogs (in which the rate of decay exceeds that of growth) would seem to indicate that we are living under drier conditions than obtained when the second forest-epoch came to a close. See EUROPE, STONE AGE.

Post-horn. See HORN.

Posting, the forwarding of passengers from place to place by means of relays of horses. Posting was long in Britain, as it is yet in some parts of the Continent, a government monopoly. See POST-OFFICE.

Post-mortem Examination. Examination of the body after death is a duty which has frequently to be discharged by medical men in various circumstances, of which the most important are (1) cases of sudden or accidental death; (2) cases of lingering illness, in which the nature of the disease had not been determined during life; and (3) cases of suspected suicide or homicide. Such examinations cannot legally be undertaken until twenty-four hours have elapsed after death, and permission or warrant must be obtained for the performance of the examination. In ordinary cases where the examination is necessary or advisable for the purpose of throwing light upon the nature of the fatal illness, and where no judicial question is involved, the consent of the parents, relatives, or guardians must be procured. In medico-legal cases the order of the coroner (in England) or of the procurator-fiscal (in Scotland) is essential. In such cases the examination should always be performed by two medical men, one of whom, it is desirable, should be an expert. In all cases the position of the body and of the surrounding objects should be carefully noted, as they often throw light upon the cause of death. The external appearances of the body, such as the presence of rigidity and of putrefactive changes, should be observed, as affording a certain clue to the period at which death occurred. In medico-legal autopsies every organ in the body should be carefully examined, and its condition briefly but accurately noted. A careful microscopic examination should follow if there be the least doubt as to the nature of the diseased condition present. Finally, in cases of suspected poisoning portions of the organs must be subjected to chemical analysis. The study of the changes wrought in the various organs by disease has been one of the most potent factors in advancing scientific medicine.

Post-nuptial Contract. See HUSBAND AND WIFE, SETTLEMENT.

Post-obit (Lat. *post obitum*, 'after death') is a bond or security given by heirs and others entitled to reversionary interests, whereby, in consideration of a sum of money presently advanced, the debtor binds himself to pay a much larger sum after the death of some person, or of himself. Whenever, as is not unusual, the payment is uncertain, and depends on the obliger outliving somebody else, very high interest is required, or rather a very much larger sum is agreed to be repaid than what is advanced. These are generally usurious bargains; but the obligee or creditor can enforce payment of the full amount; though, if there is a gross case of inadequacy in the proportions amounting to fraud, a court of equity will interfere.

Post-office, (1) a government department whose chief business it is to convey letters from place to place; and (2) any office or agency appointed by that department for the reception, despatch, or delivery of letters. Although letter conveyance is the primary work of the post-office, many other branches of business have been assumed by it. The word *post* is derived from the Latin *positus*, meaning 'placed,' 'fixed,' and comes to have its particular application from the posts, or stages, at which on the roads of the Roman empire couriers were maintained for the purpose of conveying news and despatches. Herodotus mentions that a system of couriers existed in the Persian empire; and Xenophon states that post-stations or houses were established by King Cyrus. Marco Polo describes a similar system existing in China in the 13th century, the stations being only three miles apart, thus securing great rapidity of communication. Among the ancient Aztecs in Mexico a complete system of couriers was likewise maintained, the stations being about two leagues apart, and providing a rapid means of communication by foot-messengers. In all these cases the posts seem to have been set up for government service only.

The first letter-post in the modern acceptation of the word seems to have been established in the Hanse towns in the early part of the 13th century. A line of letter-posts followed, connecting Austria and Lombardy, in the reign of the Emperor Maximilian, which are said to have been organised by the princes of Thurn and Taxis; and the representatives of the same house established another line of posts from Vienna to Brussels, connecting the most distant parts of the dominions of Charles V. The family of Thurn and Taxis continued to enjoy certain privileges in connection with these posts down to 1867, when they were ceded by treaty to the Prussian state, and have since been assumed by the German empire.

In England in early times both public and private letters were sent by special messengers only; later on they were frequently conveyed by common carriers plying with their pack-horses. In the reign of Edward I. 'posts' were established where horses could be had for hire by messengers wearing the royal livery; and in the reign of Edward II. horses were kept by private persons for hire, so that private messengers might travel 'post.' In 1481, when Edward IV. was at war with Scotland, a system of relays of horses was

established in the north (probably from York to Edinburgh) in order to provide the king with the latest news in his camp. This arrangement, however, ceased on the restoration of peace. In 1548 the charge for post-horses impressed for government service was fixed by statute at a penny a mile. Camden mentions the office of 'Master of the Postes' as existing in 1581; but the duties of the 'Master' were probably confined to the supplying of post-horses. The foreign or alien merchants in London established a post-office of their own from London to the outports in the year 1514, appointing their own postmasters; but dissensions occurred among them, and the matter was referred to the government in 1568. At this time also the English merchants complained of unfair treatment by the foreign-post; and the consequence was that the government set up a post-office for letters to foreign countries for the benefit of the English merchants. The first inland post was established by Charles I., who in his proclamation of 1635 refers to the uncertainty of communication between England and Scotland. The proclamation thus proceeds: 'Wherefore, he now commands his Postmaster of England for foreign parts to settle a running post or two, to run night and day between Edinburgh and London, to go thither and come back again in six days, and to take with them all such letters as shall be directed to any post-town in or near that road.' At the same time by-posts were to be connected with the principal towns lying off the main line of posts. In 1637 a proclamation prohibited any messengers or foot-posts to carry letters other than the messengers of the king's postmaster-general, with certain specified exceptions. This inland post was placed under the charge of Thomas Witherings, who, with William Frizell, had been entrusted with the English post for foreign letters from the year 1632. In 1640, in consequence of irregularities, Witherings was superseded in his office, which was then entrusted to Philip Burlamachi. Eight main postal lines throughout England were at this period set up. The rates of postage for a single letter were as follows: not exceeding a distance of 80 miles, 2d.; 140 miles, 4d.; for any greater distance in England, 6d.; to Scotland, 8d. In 1649, in the time of the Commonwealth, the court of Common Council for London set up a post in rivalry with that of the parliament; but the Commons promptly put an end to the undertaking. Material changes were effected in the post-office by Cromwell and his parliament in 1657, and an ordinance bearing on the subject furnishes a motive for the establishment of posts—'that they will be the best means to discover and prevent many dangerous and wicked designs against the Commonwealth.' At the Restoration the settlement of the post-office made during the Commonwealth was confirmed, and its substance was re-enacted by statute 12 Carolus II. chap. 35, which act, being the first strictly legal authority for the establishment of the post-office, has always been looked upon as its charter. Although in 1635 something was done towards establishing posts between England and Scotland, little was attempted as regards internal communication in Scotland till 1695, when the Scotch parliament passed an act for the general establishment of a letter-post. In 1683 an upholsterer named Robert Murray set up a penny post for the conveyance of letters and small parcels about London, which business was subsequently assigned to Thomas Dockwra. This undertaking was, however, seized by the government as being an infringement of its privileges, and Dockwra was granted a pension of £200 a year by way of compensation. This system was the commencement of the London Postal District service, and Dockwra was afterwards appointed its controller. About the year 1700 robberies of the posts were so frequent in the neighbourhood of the Borders that acts were passed by the Scotch and English parliaments making robbery of the post punishable with death and confiscation. In 1708 a Mr Povey attempted to set up a halfpenny post in London; but this was suppressed as the result of a lawsuit at the instance of the government. By a statute passed in 1710 the post-office was remodelled, a general post-office for the three kingdoms and the colonies being established under 'Her Majesty's Postmaster-general.' This officer was empowered to keep one chief letter-office in London, one in Edinburgh, one in Dublin, one in New York, and one in the West Indies. The Irish parliament in 1784 passed an act, giving the Irish post-office a separate existence, and creating an independent postmaster-general; but the offices were again united under the British postmaster-general in 1831. In the year 1776 a penny post for Edinburgh and Leith was set up by Peter Williamson, and carried on until about 1792, when it was absorbed by the General Post-office. In 1720 Ralph Allen (1694–1764) obtained a lease for life of the cross-posts at a rent of £6000 a year; and so greatly did he improve the revenue from this source that he realised an annual profit of £12,000, which he lived to enjoy for forty-four years.

The institution of mail-coaches (see COACHING) marks a very important period in the history of the post-office. Their introduction is due to Mr John Palmer, manager of the theatre at Bath, who submitted his scheme to Mr Pitt in 1783. In order to carry out his plan Mr Palmer was appointed Controller to the General Post-office, with a salary of £1500 a year and 2½ per cent. on any excess of revenue over £240,000 a year. The running of mail-coaches commenced in 1784, the plan being carried out, like the later great scheme of Sir Rowland Hill, in the face of vehement opposition on the part of officers of the post-office. The new method of conveyance, however, proved most successful, both on account of greater safety to the mails, and acceleration of the correspondence. In 1792 Mr Palmer was suspended from his office, an allowance of £3000 a year being made to him in lieu thereof; but after a long struggle with the Treasury parliament in 1813 made him a grant of £50,000. The mail-coach era may be said to have covered a period of sixty years, during which time the great road engineers so improved the highways that the speed of the coaches was increased from about six to fully ten miles an hour. Mails were first sent by railway in 1830 over the line between Liverpool and Manchester.

In order of time the next great feature in the history of the post-office is the uniform penny postage scheme of Mr (afterwards Sir) Rowland Hill (q.v.). He suggested his plan of reform in 1837. It evoked strong opposition within the post-office and from a section of the public without: but it was eventually adopted by a majority of 100 in the House of Commons, and the scheme was launched on the 10th January 1840. Immediately prior to that date the inland postage rates were as follows for an ordinary single letter:

From any post-office to any place not exceeding 15 miles from such post-office	4d.
Above 15 miles and under 20 miles	5d.
" 20 " 30 "	6d.
" 30 " 50 "	7d.
" 50 " 80 "	8d.
" 80 " 120 "	9d.
" 120 " 170 "	10d.
" 170 " 230 "	11d.
" 230 " 300 "	12d.
For every additional 100 miles	1d.
and for every letter carried over the Borders an additional	½d.

The extra halfpenny was charged as an indemnity for toll dues from which, by the Act 53 of Geo. III., 1813, mail conveyances in Scotland having more than two wheels were not exempt. These were the initial rates payable for single letters—i.e. letters written upon single sheets. If a letter contained an enclosure the letter became a double letter, and double postage was claimed. For a letter weighing an ounce the charge was quadrupled, and each quarter of an ounce in addition added an additional rate to the charge. Under the uniform penny postage scheme the postage was levied according to weight, commencing with a penny for a letter not exceeding half an ounce, and a penny for every additional half ounce, irrespective of distance within the kingdom which the letter had to be conveyed. The uniformity of rate as regards distance has been maintained till the present day, though the Rowland Hill scale has been altered. Thus, in 1871 the initial half ounce letter ceased (as regards inland letters), and the scale became as follows: Not exceeding 1 oz., 1d.; not exceeding 2 oz., 1½d.; not exceeding 4 oz., 2d., and ½d. for every 2 oz. up to 12 oz.; 1d. being charged for each additional ounce. In 1885 this comparatively heavy charge over 12 oz. was removed. The privilege of Franking Letters (q.v.) enjoyed by members of parliament till 1840, which was a great loss to the revenue, ceased on the introduction of the uniform penny postage. Envelopes were introduced, bearing a revenue stamp or mark for postage, and known as the Mulready envelopes, from the name of the artist who prepared the design; but the public would not take to them, and their issue was discontinued. Postage-stamps were, however, introduced at this time, and have since continued to be used. The following figures show to what extent cheap postage has stimulated the correspondence of the country. In 1839 the number of letters passing through the post, including franked letters, was 82,500,000; in 1840 the number at once rose to 169,000,000; and in 1890 the number was no less than 1,650,200,000. In addition to this mass of written matter, besides 217,100,000 post-cards, the following articles passed through the post in 1890: Book-packets and circulars, 441,900,000; newspapers, 159,300,000. For some years after the introduction of Rowland Hill's scheme there was a deficit in the post-office revenue, but this was soon covered by the rapid growth of business, and for many years the post-office has paid in large yearly profits to the Treasury. In 1890 the gross revenue from all branches of post-office business was £12,211,614; the expenditure, £8,865,527; and the net revenue, £3,346,087. Halfpenny post-cards were introduced in October 1870, and the penny postage upon newspapers was reduced to ½d. In 1898 2,012,300,000 letters were posted; post-cards, 360,400,000; book packets and circulars, 727,300,000; newspapers, 150,900,000; parcels, 67,823,000. In 1898 penny postage was introduced for the British Empire, except Australasia and the Cape, and some minor possessions. Letters, post-cards, book packets, and newspapers may be redirected without additional postage if reposted within one day.

From 1891 the railway companies were empowered to convey single letters for the public, between their stations, on behalf of the post-office, provided the letters do not exceed 1 oz. in weight. Such letters must bear a postage-stamp of the value of 1d., which goes to the revenue, and a railway stamp of the value of 2d., which goes to the companies as payment for conveyance.

In March 1891 a system of express delivery for letters and parcels was established in London and certain of the more important towns in the kingdom; and shortly thereafter it was made general throughout the country. The delivery is effected by means of the messenger force employed in the telegraph service. When railway, omnibus, or tramcar conveyance only is used by the messenger, the fee, in addition to the ordinary postage, is twopence for the first mile, and threepence for each additional mile. Higher fees are charged for cab conveyance.

Postal Union.—Under the terms of a treaty concluded at Berne on the 9th October 1874, the object of which was to secure uniformity in the treatment of correspondence, and the simplification of accounts, as well as the reduction of rates within certain limits, and whose provisions were carried into operation generally on the 1st July 1875, the whole of Europe, the United States of America, Egypt, British India, and all the colonies of France were at the outset, or shortly thereafter, included in the Union, and many other countries and colonies have since joined it. The rates of postage to the several states concerned will be found set forth in the British *Post-office Guide*. The international accounts in respect of postages are based upon a month's return of correspondence taken every third year. The rates of postage *to* Great Britain are not always the same as those *from* Great Britain, each country having a certain limited discretion in fixing rates.

Registered Letters.—In 1779 the postmaster-general issued an order that postmasters should dissuade the public from sending letters by post containing cash in gold or silver, rings, or bracelets, &c.; but this order was rescinded in 1792. At the same time postmasters were again authorised to accept such letters; but before placing them in the mail-bags they were required to copy the addresses of the letters on the front of the letter bill and to tie the letters up with the bill. This mode of giving greater security to letters of value seems to have been the initial stage in the development of the registered letter system. The modern plan of registration is based on the principle that every registered letter must be signed for in passing from hand to hand; and, although the postmaster-general gives guarantee (under special conditions) to but a comparatively small amount, the system affords almost absolute security of transmission. The number of letters registered in the United Kingdom in 1890 was 11,357,935. The fee for inland registration, in addition to the ordinary postage, had for many years been fixed at twopence; but on the 1st June 1891 a combined system of registration and insurance was introduced for letters and parcels, with fees ranging from twopence to sixpence, and a maximum insurance of £25.

Money Orders.—In the year 1792, by permission of the postmaster-general, some half-dozen clerks who had charge of the 'country roads,' or despatching divisions, in the London General Post-office, set up a system of remittances for the public to and from the post-offices in England and the chief post-offices in Edinburgh and Dublin, the postmasters at these places acting as agents in the scheme. This was the origin of the money-order system, which for a long period was carried on by the clerks on their own account. It was not till the year 1838 that it became a recognised branch of the post-office establishment. In the earlier years the rates of commission were very high, but for many years the charges have been, especially for small amounts, on a very moderate scale. In the period from 1859 till the present time the money-order system has been extended to a great many of the colonies and to foreign countries, and every year further extensions are being made. Money may also be transmitted by telegraph between all telegraph and money-order offices, and also to Belgium, Germany, and Holland. The total business done in 1890 was:

Inland orders, 9,027,750, £23,333,417; colonial orders, 453,102, £1,631,616; foreign orders, 893,292, £2,200,872.

Postal Orders.—In pursuance of the recommendations of a committee appointed by the Treasury, of which the late Mr George Moore, the philanthropist, was chairman, the transmission of money by means of postal orders was put into operation on the 1st January 1881. This simple method of remitting small sums of money has grown rapidly in public favour, and each year adds largely to the amount of business done. In 1890 the total number of orders issued was 44,712,548, representing an aggregate value of £17,737,802, 4s.

Post-office Savings-banks.—By Act 24 Vict. chap. 19, a system of savings-banks in connection with the post-office was established in 1861, affording great facilities for thrift to the industrial classes and to young people. The rate of interest payable to depositors is 2½ per cent., calculated upon complete pounds remaining with the post-office complete months. No single depositor may deposit more than £30 in any one year. The number of offices opened for savings-bank business up to the 31st March 1862 was 2532, while on the 31st December 1889 the number open was 9353. In this latter year the deposits numbered 8,101,120, amounting to £19,814,308, and the withdrawals were 2,757,848, amounting to £16,814,268. On the 31st December 1889 a total amount, including interest, remained to the credit of depositors of £62,999,620. The interest credited to depositors for the year was no less than £1,443,186. The post-office savings-bank is largely used by friendly societies, provident institutions, and penny banks as a safe place of deposit for their funds. Since 1880 depositors have been enabled to invest their savings in government stocks with little or no trouble. On the 31st December 1889 the total amount of stock so held was £4,175,634, distributed over 46,993 persons. Under regulations of 1888 the minimum amount of stock purchasable was reduced from £10 to 1s. See SAVINGS-BANKS.

Government Insurances and Annuities.—An Act 27 and 28 Vict. chap. 43, 1864, empowered the postmaster-general to grant life-insurance policies and annuities within certain limited amounts; and the scheme was brought into operation on the 16th April 1865. These branches of business have not developed beyond very narrow limits, and, in so far as the scheme may have been devised to make life insurance and the buying annuities on the part of the less well-to-do more general, the attempt has hitherto proved a failure.

Post-office Telegraphs.—Prior to 1870 the business of conveying telegraphic messages for the public was in the hands of several rival telegraph companies and the railway companies; but by the Act 31 and 32 Vict. chap. 110, 1868, the postmaster-general was authorised to acquire, work, and maintain electric telegraphs; and by Act 32 and 33 Vict. chap. 73, he acquired (with certain exceptions) the exclusive privilege of sending telegraphic messages within the kingdom. The actual transfer of the working system took place on the 5th February 1870. The tariff was, like the inland postage, a uniform tariff within the United Kingdom, the minimum charge being 1s. for twenty words, with free addresses. In the first complete year of the new management (1870–71) the total number of telegrams of all classes transmitted was 9,850,177. On the 1st October 1885 the minimum charge for a telegram was reduced to 6d. for twelve words, addresses ceasing to be sent free. In the year 1889–90 the number of messages transmitted was 62,403,399. The total sum laid out as capital in connection with the purchase of the telegraphs was £10,880,571; and the annual interest on this sum, amounting to £299,216, is not borne on the post-office votes. In the year 1898 the number of telegrams was 68,810,786, and the revenue, £2,130,973. The number of offices for postal telegraph business in 1898 was 8175 (see TELEGRAPH). The post-office had also in 1899 53,000 miles of telephone trunk-wires, and connections with the National Telephone Company's exchanges (see TELEPHONE).

Parcel Post.—This is the most recent of the greater undertakings entered into by the post-office. By the Post-office (Parcels) Act, 1882 (45 and 46 Vict. chap. 74), the post-office was empowered to convey parcels by post on different conditions from ordinary postal packets; the remuneration to the railway companies for the conveyance of the parcels in bulk being fixed at eleven-twentieths of the gross inland postage received for the parcels, the post-office performing all duties of collection and delivery. This business was entered upon by the post-office on the 1st August 1883, the parcels conveyed being exclusively inland parcels. At the outset the maximum weight of a parcel was fixed at 7 lb. On the 1st May 1886 the maximum weight was raised to 11 lb., and an alteration made in the scale of postage, the charge for a parcel of 11 lb. being fixed at 1s. 6d. In the first year of the parcel post the number of parcels transmitted was upwards of 22,900,000. On the 1st July 1885 parcel business was extended to certain of the colonies and to foreign countries, and from year to year this connection with places abroad becomes more widely extended. In the year ended 31st March 1890 the total number of parcels of all kinds delivered in the United Kingdom was 42,852,570, the gross postage upon which was £952,113. This vast system of parcel carriage is said not to have damaged to any very considerable extent the parcels business of the railway companies, and consequently it must be held to be a new convenience created for the public, the value of which it is impossible to estimate.

Inland Revenue Licenses.—Through the medium of the post-office the inland revenue department finds a ready means of issuing a great variety of licenses throughout the country. In the year ended the 31st March 1890 the number of licenses so distributed was 1,518,136, representing a sum of £908,163.

Mail-packet Service.—Occasional reference is made in old writings, and in official records, to the employment of vessels called packets, for the conveyance of the mails, but there seems hardly any continuous account of the services performed by those vessels. In the time of Charles I. packets between Dublin and Chester, and between Milford Haven and Waterford, conveyed government despatches, and in 1639 one Nicholas Herbert agreed to have his barque in readiness at Whitehaven, 'with one sufficient master, and other meet and able sailors,' to carry letters for His Majesty or the council at Dublin for £10 per lunar month. It would seem that for some time anterior to 1788 the packets belonged either to the crown, to members of the post-office staff, or to their friends, for in that year a commission upon fees of public offices recommended that this system should be abandoned, and that contracts should be obtained by public advertisement. The recommendation was, however, only partially acted upon at that time, and no public contracts were entered into, apparently, until after 1837, at which period the packet service was placed under the management of the Admiralty. Another committee in 1848 strongly urged an extension of the contract system, and a similar recommendation was made by Lord Canning's Committee of Inquiry into packet-contracts in 1853. This committee also recommended that the stipulation as to the arming of the packets

should be omitted in future contracts, and the committee's views in this matter were then given effect to. The mail-packet contract business remained in the hands of the Admiralty till the 1st April 1860, when the whole management was taken over by the post-office. In order to establish rapidity and regularity of service, it has been necessary from time to time to grant vast subsidies to the mail-packet contractors, in those cases where the exigencies of trade had not secured these conditions; but the growth of commerce and greater competition have enabled the post-office in many cases to obtain easier terms. At the close of the 17th century a mail-packet was a vessel of some 85 tons, and in the last years of the 18th century a mail-packet on the Falmouth station, reckoned fit to proceed to any part of the world, was one of about 179 tons. The packets at this time sailing to and from the Continent were of about 70 tons burthen. About 1840 packets performing the American service were vessels of about 400 or 500 tons burthen. Steam-vessels were first employed in the packet service in 1821, since which time vast strides have been made both in the speed and carrying capacity of these ships. The British mail-packets are to be seen in almost every sea on the globe. For the Atlantic service steamers of from 7000 to 10,000 tons are employed, making the transit from shore to shore in six days. So late as 1829 the time allowed for a packet trip to and from America was 105 days. The contract services at home are very numerous, and those to foreign stations are almost co-extensive with the high seas. In the year 1889–90 the total payment made by the post-office for packet services was £665,375, full details of which will be found in the postmaster-general's annual report.

Rates and Regulations.—In the scope of an article like this it is impossible to review the past rates of postage and changes of regulations that have taken place from time to time. The conditions applicable to the business in relation to the public will be found fully set forth in the Post-office Guide, which may be consulted at any post-office, and to which the reader is referred.

Staff.—The highest authority in the post-office is the postmaster-general. This official is a member of the government, a privy-councillor, and sometimes a cabinet minister. All important measures of administration, appointments of officers, and dismissals are passed under the authority of the postmaster-general in the form of minutes. The chief permanent officials are: the secretary, a financial secretary, four other secretaries in London, a surveyor-general in Scotland, and a secretary in Ireland. The several secretaries under the first secretary take charge of separate branches of post-office business. Another important officer is the receiver and accountant general. This officer is responsible for the whole vast accounting work of the post-office, the collection of its revenue, and the distribution of its expenditure. He has no power, however, except by effecting economies of work or reforms of method, to reduce the latter or to increase the former. The bases of revenue and expenditure are fixed by higher authority. The total number of persons employed by the post-office (1890) is 113,550. Of these 61,054 are established officers, and 52,496 unestablished and persons not giving their whole time to post-office work. The total number of employees comprises 89,373 males and 24,177 females. The salary of the postmaster-general is £2500 per annum, and of the chief-secretary a maximum of £2000. On a change of government the postmaster-general demits his office.

Espionage of Letters.—The post-office statute of Queen Anne contains a prohibition, repeated in subsequent acts, against letters being opened or detained by persons in the service of the post-office, except under a warrant from one of the principal secretaries of state. During the 18th century such warrants were often granted upon very trivial pretexts. At Bishop Atterbury's trial in 1723 copies of his letters, intercepted in the post, were produced as evidence against him; and it would seem that about 1735 a system was kept up at immense expense for the examination of home and foreign correspondence. In 1782 the correspondence of Lord Temple, then lord-lieutenant of Ireland, was subjected to such treatment in the post. The 19th century brought a change for the better in this respect, and in 1806 Lord Spencer initiated the custom of recording the dates of all warrants granted, and the grounds upon which they were issued. Since 1822 the warrants have been preserved at the Home Office; and a House of Commons return in 1853 shows that, in the preceding ten years, only six letters were detained and opened—four in cases of felony. When Sir James Graham (q.v.) was Home Secretary in 1844 a warrant was issued for the arrest and opening of the letters of Mazzini, the matter contained in them being conveyed to the Austrian minister. This act involved the government of the day in serious public obloquy, and produced a widespread, though groundless, distrust in the security of the ordinary correspondence of the country. It may safely be held that this power of opening letters in the post has been very rarely exercised in recent years.

Dead-letter, or Returned-letter Office.—A department of the post-office appointed to deal with letters, books, newspapers, &c. which cannot be delivered to the persons to whom they are directed. When a letter or other postal packet is refused at the address which it bears it is kept by the postmaster, if an inland letter, &c., one day, and if a colonial or foreign letter, &c., three days, before being sent to the returned-letter office. Inland letters are here opened, and those which contain the writers' addresses are at once returned to them; while those which furnish no indication of the addresses of the senders, and contain nothing of value, are at once destroyed. Letters which bear the senders' addresses on the outside, in the form of medallion or otherwise, are, however, usually returned without being opened. Foreign and colonial letters, after being retained from one week to one month, are returned unopened to the country of origin for disposal. A register is kept of letters found to contain value. In the year 1889–90 the following numbers of articles were received in the various offices constituting this department: letters, 6,311,102; post-cards, 841,076; book-packets (including circular-letters passing at book-post rates), 6,661,201; newspapers, 551,022; patterns or samples, 27,486; parcels, 107,863. Of the letters 119,386 were re-issued to corrected addresses, and 5,539,551 returned to the senders, while 214,839 were returned unopened to foreign countries. Of the total parcels received 81,277 were either re-issued to corrected addresses or returned to the senders. The returned-letter department has not only principal offices in London, Edinburgh, and Dublin, but branch offices in the other more important towns.

Offences against the Post-office.—In view of the vastly important services rendered to the public by the post-office, involving the imposition of great responsibility upon its officers, and of the necessity which obviously exists for the protection of the revenue (the conveyance of letters being a state monopoly), the legislature have thought fit to pass special enactments for the regulation of the one and the safeguarding of the

other. In addition, enactments have been passed from time to time bearing upon the other branches of post-office business. The following are some of the offences recognised in the enactments: Every person employed by or under the post-office who steals, secretes, or destroys a post-letter is guilty of felony, and if it contain a chattel or money the punishment is increased. Strangers also who steal letters or other postal packets out of the custody of the post-office or its officers are likewise guilty of felony, and similarly punishable; and a person who fraudulently retains or wilfully keeps or detains a letter or other postal packet delivered to him by mistake, or which having been lost in course of conveyance he may have found, is punishable by fine and imprisonment. The moment a letter or other postal packet is put into the post-office, or is delivered to a person authorised to receive such missives for the post, the protection of the statutes commences, and it ceases on the letter or packet being delivered at the place of its address. If a postman delay the delivery wilfully, or if an officer of the post-office disclose or intercept or wilfully delay a telegraphic message, he commits a misdemeanour. Receivers of post-letters or their contents stolen or taken from the post-office are guilty of felony. By the 1 Vict. chap. 36 sect. 2, any person sending or conveying otherwise than by post letters or packets, not exempted from the exclusive privilege of the postmaster-general, or performing otherwise than by the post any services incidental to conveying letters or packets from place to place, is liable to a penalty of £5 for every such letter or packet. This exclusive privilege or monopoly does not extend to newspapers. There are, however, exceptions to the general rule as regards letters or packets. Thus, a letter may be conveyed by a private friend and not by the post-office. Letters sent by messengers on purpose, on the private affairs of the sender or receiver, commissions and legal writs, letters of merchants sent by their own vessels or along with goods to which they relate, are likewise excepted. But no person is permitted even to collect these excepted letters for the purpose of sending them in the manner described, for this is infringing the exclusive privilege of the post-office. Moreover, certain persons are expressly prohibited from carrying letters even gratuitously—viz. common carriers, unless the letters relate to goods in their carts or wagons; owners, masters or commanders of ships, except letters of the owners of the ships or such as relate to goods on board; and passengers or other persons on board ships.

By statute the transmission of telegrams within the United Kingdom is secured to the postmaster-general as a monopoly, and telegrams enjoy many of the protective privileges applicable to post-letters. The postmaster-general has power to arrest in the post any missive bearing thereon any words, marks, or designs of an indecent, obscene, or grossly offensive character. Under the Post-office (Money Orders) Acts, 1848 to 1883, an officer of the post-office who with a fraudulent intent issues a money order or postal order, or re-issues a postal order previously paid, is liable to penal servitude not exceeding seven years; and any person who forges an order, or utters a forged order, is liable to penal servitude for a longer term. An officer of the post-office who fraudulently embezzles or misappropriates moneys or securities entrusted to or received by him by virtue of his employment is liable to penal servitude not exceeding fourteen years.

By 43 and 44 Vict. chap. 33, sect. 3, any person who, with intent to defraud, obliterates, adds to, or alters any such lines or words on a postal order as would, in the case of a cheque, be a crossing of that cheque, or knowingly offers, utters, or disposes of any order, with such fraudulent obliteration, addition, or alteration, is guilty of a felony, and is liable to the like punishment as if the order were a cheque. By the Act 45 and 46 Vict. chap. 74, relating to the parcel post, that act is to be deemed to be a post-office act within the meaning of the Post-office (Offences) Act, 1837 (1 Vict. chap. 36), and subject to its provisions. The Post-office Acts apply to *parcels* in like manner as they apply to other postal packets. Act 47 and 48 Vict. chap. 76—the Post-office (Protection) Act, 1884—deals with a variety of offences under the following heads: prohibition of placing injurious substances in or against post-office letter-boxes; prohibition of sending by post explosive, dangerous, or deleterious substances, or indecent prints, words, &c.; prohibition of affixing placards, notices, &c. on a post-office, letter-box, or other post-office property; prohibition of imitation of post-office stamps, envelopes, cards, forms, and marks; prohibition of fictitious stamps; prohibition of false notice implying that any place is a post-office, postal telegraph office, or post-office letter-box; obstruction of officers of the post-office or of business in a post-office; retaining of clothing by officers of the post-office on ceasing to be officers; forgery and improper disclosure of telegrams. Contraventions of these prohibitions entail penalties generally ranging from twelve months' imprisonment with hard labour, or a fine of £200, to fines not exceeding forty shillings.

Foreign Post-office Systems.—The advantages of the post are now enjoyed, in a greater or less degree, by all civilised countries; and the several systems bear in their main features a general resemblance to the British system, upon which, in many cases, they have been modelled. At the same time details of marked difference may be observed, each country having adapted its system to its own particular wants. Thus, in certain countries subscriptions to the newspapers and accounts for merchandise are collected by the post-office; the parcel post conveys larger and heavier articles than are conveyed in Great Britain; a system of sending through the post letters of declared value is in force in some; and a different means is employed for transferring mails to and from mail trains while running. Besides this, the classification of postal matter in regard to rates of postage is not uniform. The amount of matter conveyed through the post between Great Britain and certain foreign countries is enormous—e.g. the average number of sacks of mails despatched weekly in 1890 from Britain to the United States was 1200, and to the Australian colonies 410.

United States.—The beginnings of a postal service in the United States date from 1639, when a house in Boston was employed for the receipt and delivery of letters for or from beyond the seas. In 1672 the government of New York colony established 'a post to goe monthly from New York to Boston;' in 1702 it was changed to a fortnightly one. A general post-office was established and erected in Virginia in 1692, and in Philadelphia in 1693. A deputy postmaster-general for America was appointed in 1692: and by act of parliament in 1710 (see p. 347) he was directed to keep his principal office in New York, 'and other chief offices in some convenient place or places in other of Her Majesty's provinces or colonies in America;' a monopoly was established which included also the transport of travellers, and a tariff was fixed. The system, however, proved a failure, until 1753, when Benjamin Franklin became postmaster-general: when he was removed from office in 1774 the net revenue exceeded £3000.

In 1789, when the post-office was transferred to the new federal government, the number of offices

in the thirteen states was only about seventy-five. A conspectus of the remarkable progress in the ensuing century is supplied in the table below. Outstanding events in the history of the American postal service have been the negotiation of a postal treaty with England (1846); the introduction of postage-stamps (1847), of stamped envelopes (1852), of the system of registering letters (1855); the establishment of the free-delivery system, and of the travelling post-office system (1863); the introduction of the money-order system (1864), of postal cards (1873), and, between the last two dates, of stamped newspaper-wrappers, and of envelopes bearing requests for the return of the enclosed letter to the writer in case of non-delivery; the formation of the Universal Postal Union (1873); the issue of 'postal notes' payable to bearer (1883); and the establishment of a special delivery system (1885), under which letters bearing an extra ten-cent stamp are delivered by special messengers immediately on arrival. The telegraph is not in the hands of the post-office, and among other features not yet adopted by the United States service are post-office savings-banks and the parcel post. The postmaster-general is a member of the cabinet. Under him about 100,000 persons are employed, of whom some 60,000 are postmasters. Most of these, except letter-carriers and clerks, are liable to be removed on the accession to federal office of a new political party. The following table shows the increase, during the first century of the department's history, in offices, length of mail routes in miles, revenue, &c.

Years.	Offices.	Miles.	Revenue.	Expenditure.
1790.....	75	1875	$37,935	$32,140
1800.....	903	20,817	280,804	213,994
1810.....	2,300	36,406	552,366	495,969
1820	4,500	72,492	1,111,927	1,160,926
1830.....	8,450	115,176	1,850,583	1,932,708
1840.....13,468		155,739	4,543,522	4,718,236
1850.....18,417		178,672	5,552,971	5,212,953
1860.....28,498		240,954	8,518,067	19,170,610
1870.. 28,492		231,232	19,772,221	23,998,837
1880.....42,989		343,888	33,315,479	36,542,804
1890.....62,401		..	60,858,783	65,645,083

As will be seen, the United States post-office department, unlike that in Great Britain, is carried on at a loss; this is due to the large amount of postal matter of certain classes carried at less than the cost of distribution, and to some kinds of correspondence carried free. In 1898 there were 12,225,706,220 pieces of mail handled, 15,416,292 registered packages, 1,661,416 through registered ponches, &c. In 1890 there were conveyed by post:

Letters, post-cards, &c.	2,289,950,015
Newspapers, &c.	778,428,515
Other articles	519,247,199
Articles sent free of postage	376,509,165
Articles of all kinds for foreign countries	41,273,312
Grand total	4,005,408,206

The number of post-offices in the United States is larger than in any other country; but as regards the number of persons employed the United States takes third rank. It provides a post-office for every 1003 persons, while in Great Britain the proportion is one to every 2105 persons.

See the articles STAMPS, TELEGRAPH. The following works may also be consulted: Postmaster-general's Annual Reports, issued yearly since 1855; *Her Majesty's Mails*, by Lewins; *Life of Sir Rowland Hill; The History of Penny Postage*, by Sir R. Hill and G. B. Hill (1880); *Fifty Years of Pub ic Work*, by Sir Henry Cole (1884); *The History of the Post-office to 1836*, by H. Joyce (1893); *Forty Years at the Post-office*, by F. E. Baines (1895); *The Royal Mail* (1885), and *The Post in Grant and Farm* (1895), by the present writer.

Potassium (sym. K, equiv. 39) is one of the alkaline metals. The letter K is selected as its symbol, as being the first letter of *Kali*, the Arabic word for potash, the letter P being already taken as the symbol for phosphorus. The following are the chief characters of this metal. It is of a bluish-white colour, and presents a strong metallic lustre. It melts at 146·5° (62·5° C.), and at a red heat is converted into vapour. Its affinity for oxygen is so great that on exposure to moist air it immediately becomes covered with a film of oxide, and hence it must be kept below the surface of naphtha. When heated it burns with a violet flame. Its intense affinity for oxygen is well shown by throwing it into water, on which, from its low specific gravity, ·865, it floats. The metal abstracts oxygen from the water, and forms oxide of potassium (potash); while the liberated hydrogen carries off a small portion of the volatilised potassium, and, taking fire from the heat evolved by the energetic chemical action, burns with a brilliant violet flame. The experiment is a very beautiful one, the burning metal swimming about rapidly on the water, and finally disappearing with an explosion of steam, when the globule of melted potash becomes sufficiently cool to come in contact with the water.

Potassium does not occur in the native state, and can only be obtained by the reduction of its oxide, potash. In 1807 Davy prepared it by decomposing its hydrated oxide (potash) by means of a voltaic current, but this process is not applicable on the large scale. It is now usually manufactured by distilling a mixture of carbonate of potash and charcoal in an iron retort.

If proper proportions are taken, the mixture is wholly converted into carbonic oxide and potassium, as is shown in the equation:

Carbonate of Potash. Carbonic Oxide.

$$K_2CO_3 + 2C = K_2 + 3CO.$$

Potassium forms two compounds with oxygen, viz. a protoxide, K_2O, which constitutes potash, and is strongly basic, and a peroxide, K_2O_4. Of these the former is the only important one.

Potash can be procured in the anhydrous form by heating thin slices of the metal in air perfectly free from moisture or carbonic acid. It is white, very deliquescent, and caustic. When moistened with water it becomes incandescent, and the water cannot be expelled by any degree of heat. A far more important substance is the *Hydrate of Potash* or *Caustic Potash* ($KOH = K_2OH_2O$). This is commonly prepared by dissolving carbonate of potash in ten times its weight of water, and gradually adding to the boiling solution a quantity of slaked lime, equal in weight to half the carbonate of potash used. The resulting compounds are carbonate of lime, which falls as a precipitate, and hydrate of potash, which remains in solution; the changes being expressed by the equation:

Carbonate of Potash. Slaked Lime. Carbonate of Lime. Hydrated Potash.

$$K_2CO_3 + CaOH_2O = CaCO_3 + 2KOH.$$

The clear supernatant fluid is removed by decantation, or by means of a siphon, into a clean silver or iron basin, and is rapidly evaporated till it flows tranquilly like oil; it is then either cast into cylinders in metallic moulds, or is poured upon a cold slab, and solidifies on cooling. As so obtained it is very impure, but by solution in alcohol and evaporation a very pure article is produced.

Hydrated potash, on solidifying after fusion, occurs as a hard, grayish-white, opaque body, with a crystalline fracture, which may be readily again fused into a colourless oily fluid, but which only

volatilises at a very high temperature. It is soluble in about half its weight either of water or of alcohol, and rapidly absorbs both carbonic acid and moisture from the atmosphere. It acts as a powerful caustic, and quickly destroys both animal and vegetable tissues, and hence its solutions can only be filtered through asbestos or pounded glass or sand. Its affinities are so powerful that few vessels are capable of resisting its influence. Its solution must be preserved in glass bottles into the composition of which no oxide of lead enters, as it has the property of dissolving this oxide out of the glass. Vessels containing silica (porcelain, earthenware, &c.) are decomposed, and platinum itself is oxidised when heated in contact with it.

The *salts* which potash forms with acids are for the most part readily soluble in water, and colourless, unless (as, for example, in permanganate of potash) the acid is coloured. Most of them are crystallisable, and they all communicate a violet tint, characteristic of potash, to the flame of spirit of wine and to that of the blowpipe. Many of them occur in animals and vegetables, and the ashes of plants contain them in large quantity.

Carbonate of Potash, K_2CO_3, is obtained by burning plants in dry pits, dissolving the ashes in water, evaporating till the sulphates, chlorides, &c. separate in crystals, and then boiling the mother liquid to dryness in iron pots. The quantity of pure carbonate of potash contained in it is liable to great variation, and for pharmaceutical purposes it must be dissolved in water and crystallised, the crystals containing about 20 per cent. of water. Carbonate of potash is extremely deliquescent, and is soluble in less than its own weight of water, but is insoluble in alcohol. It has an acrid, alkaline taste, and its reaction upon test-paper is strongly alkaline. It is a compound of great importance, both as a chemical reagent and as entering largely into the preparation of most of the other compounds of potash, and into the manufacture of soap and glass. The commercial carbonate is often called *Pearl Ashes*. *Bicarbonate of Potash*, $KHCO_3$, is obtained in white rhombic prisms, by passing a current of carbonic acid gas through a strong solution of carbonate of potash. These crystals are permanent in the air, but are decomposed by heat; water and carbonic acid being evolved, and the simple carbonate left. This salt is much less soluble than the carbonate, requiring four parts of cold water for its solution, which is nearly neutral to test-paper, and has a much milder taste than the preceding salt. It is employed as an antacid in medicine. The *Sulphate*, K_2SO_4, and *Bisulphate*, $KHSO_4$, may be prepared by treating potash with sulphuric acid. *Nitrate of Potash* has been already described under the head NITRE. *Chlorate of Potash*, $KClO_3$, occurs in white rhomboidal tablets of a pearly lustre. It has a cooling taste like that of nitre. It fuses at a gentle heat without decomposition, but on increasing the heat it gradually gives off all its oxygen, and is converted into chloride of potassium, according to the equation:

Chlorate of Potash.		Chloride of Potassium.		Oxygen.
$2KClO_3$	=	$2KCl$	+	$3O_2$.

It is not very soluble, as it requires for solution 16 parts of cold and 1·7 parts of boiling water. It even surpasses nitrate of potash as an oxidising agent; and if combustible substances, such as carbon, sulphur, or phosphorus, be heated or forcibly rubbed with it, a detonation or explosion occurs. This salt is employed in the manufacture of Matches (q.v.), in certain operations in calico-printing, and for filling the friction-tubes employed for firing cannon: the best mixture for these tubes consisting of 2 parts of this salt, 2 of sulphide of antimony, and 1 of powdered glass. A mixture known as *White Gunpowder*, consisting of chlorate of potash, dried ferrocyanide of potassium, and sugar, has been employed for blasting purposes, but its preparation is accompanied by so much danger that it is seldom used. This salt does not occur as a natural product, but may be obtained along with chloride of potassium by passing a current of chlorine gas through a hot solution of caustic potash. The two salts are easily separated by crystallisation, as the chlorate is comparatively insoluble, and the chloride extremely soluble. *Hypochlorite of Potash* can only be obtained in solution. Under the title of *Eau de Javelle*, it is sold as a bleaching agent. It is obtained by passing chlorine gas through a cold dilute solution of carbonate of potash, when chloride of potassium and hypochlorite of potash are formed, from which the chloride may be removed by crystallisation. The *Phosphates of Potash*, formed by the different varieties of phosphoric acid, are sufficiently noticed in the articles PHOSPHORUS and MANURE. The *Silicates of Potash* are important compounds in connection with the manufacture of glass; they also enter into the composition of Fuchs's *Soluble Glass* (see GLASS), or *Water-glass*, and have been employed as a coating by which the decay of magnesian and other limestones may be prevented. The *Chromate* and *Bichromate of Potash* are noticed in the articles CHROMIUM and CALICO-PRINTING. The haloid salts of potassium may be passed over very briefly. The *Chloride of Potassium*, KCl, is obtained in large quantity in the preparation of chlorate of potash, or may be procured by burning potassium in chlorine gas, when the result of the brilliant combustion which takes place is this salt. In its general characters it closely resembles common salt, NaCl, except that the former communicates a violet and the latter a yellow tint to the flame of alcohol. It is a constituent of sea-water, of salt marshes, and of many animal and vegetable fluids and tissues. The *Bromide* and *Iodide of Potassium* are noticed in the articles BROMINE and IODINE. *Fluoride of Potassium*, KFl, possesses the property of corroding glass. There are several sulphides, the most important being the *Liver of Sulphur*, prepared by fusing together carbonate of potash and sulphur. Besides its use in skin diseases, it is much employed by florists to prevent mildew on roses. The *Yellow* and the *Red Prussiate* (or the *Ferrocyanide* and *Ferricyanide*) *of Potash* are noticed in the article FERRIDCYANOGEN. The *Cyanide of Potassium*, KCy, may be procured by heating potassium in cyanogen gas, when brilliant combustion occurs, and the resulting product is this salt. It may, however, be more cheaply and easily prepared by fusing together 8 parts of ferrocyanide and 3 of carbonate of potassium. This salt forms colourless deliquescent crystals very soluble in water. It exhales an odour of hydrocyanic acid, and is nearly as poisonous as that acid. Its great deoxidising power at a high temperature renders it a valuable agent in many of the finer operations of metallurgy.

The following are the ordinary tests for the potassium compounds: (1) Solution of tartaric acid added in excess to a moderately strong solution of a potassium salt gives after some time a white crystalline precipitate of cream of tartar (see TARTARIC ACID). The result is hastened by stirring or shaking. (2) Solution of bichloride of platinum gives a crystalline yellow precipitate, which is a double salt of bichloride of platinum and chloride of potassium. If not previously acid, the mixture to be tested should be acidulated with hydrochloric acid. (3) The violet tint occurring in the presence of potassium in the outer flame of the blowpipe.

or in the flame of spirit, has been already noticed. (4) The spectrum of a flame containing potassium exhibits a characteristic bright line at the extreme limit of the red, and another one at the opposite violet limit of the Spectrum (q.v.).

In medicine the following compounds are used: *Caustic Potash*, or *Hydrate of Potash*, KOH, which occurs in hard white pencils. From its power of dissolving the animal tissues, it is sometimes used as a caustic, although its great deliquescence renders it somewhat difficult to localise its action to the desired spot. In bites of venomous serpents, mad dogs, &c. it may be applied with advantage, and it is useful in destroying warts and fungoid growths of various kinds. *Solution of Potash*, commonly known as *Liquor potassæ*, is obtained by the process already given for the preparation of hydrate of potash. Liquor potassæ, in combination with a tonic infusion, is of service in cases of dyspepsia which are accompanied with excessive acidity of the stomach, such, for example, as often occur in habitual spirit-drinkers. It is also frequently given with the view of rendering the urine alkaline, or of diminishing its acidity in cases in which that secretion is too acid. The usual dose is ten drops, gradually increased to as much as a fluid drachm. *Acetate of Potash*, $KC_2H_3O_2$, is obtained by the action of acetic acid on carbonate of potash, and occurs in white foliaceous satiny masses. In its passage through the system it is converted into carbonate, and thus renders the urine alkaline. In small doses, as from a scruple to a drachm, it acts as a diuretic, and is of service in some forms of dropsy. Combined with other potass-salts, it is much given in acute rheumatism. The two carbonates and the sulphurated potash have been already referred to.

The *Chlorate of Potash* has come much into use as a popular remedy for sore throats. For this purpose it is usually employed in the form of compressed pellets, which are allowed to dissolve slowly in the mouth.

Potato (*Solanum tuberosum*; see SOLANUM), one of the most important of cultivated plants, and in universal cultivation in the temperate parts of the globe. It is a perennial, having herbaceous stems, 1 to 3 feet high, without thorns or prickles; pinnate leaves with two or more pair of leaflets and an odd one, the leaflets entire at the margin; flowers about an inch or an inch and a half in breadth, the wheel-shaped corolla being white or purple, and more or less veined, followed by globular, purplish fruit, of the size of large gooseberries; the roots producing tubers. The herbage has a slightly narcotic smell, although cattle do not refuse to eat a little of it, and the tender tops are used in some countries like spinach. The tubers are, however, the only valuable part of the plant.

It was long customary to speak of the potato as a native of mountainous districts of tropical and subtropical America; but it has never been clearly determined where it is really indigenous, and where it has spread after being introduced by man. Humboldt doubted if it had ever been found truly wild; but subsequent travellers, of high scientific reputation, express themselves thoroughly satisfied on this point. It has been rendered certain that long before the Spaniards reached the New World the potato was cultivated by the Incas and other Andean nations. It seems to have been first brought to Europe by the Spaniards, from the neighbourhood of Quito, in the beginning of the 16th century, and to have spread from Spain into the Netherlands, Burgundy, and Italy, but only to be cultivated in a few gardens as a curiosity, and not for general use as an article of food. It is said to have been brought to England from Virginia by Sir John Hawkins in 1563; and, again, in 1586 by Sir Francis Drake, to whom indeed a statue, as the introducer of the potato, was erected at Offenburg, in Baden, in 1853. Anyhow, it cannot have attracted much notice; and though Raleigh is believed to have planted potatoes both at his Devonshire birthplace Hayes, and on his Munster estates, it was a long time before they began to be extensively cultivated. It long received throughout almost all European countries the same name with the Batatas or Sweet Potato (q.v.), which is the plant or tuber meant by English writers down to the middle of the 17th century in their use of the name potato. Gerard, in his *Herball*, published in 1597, gives a figure of our potato under the name of *Batata Virginiana;* but so little were its merits appreciated that it is not even mentioned in the *Complete Gardener* of Loudon and Wise, published more than a century later, in 1719; whilst another writer of the same time says it is inferior to skirret and radish! It began, however, to be imagined that it might be used with advantage for feeding 'swine or other cattle,' and by-and-by that it might be useful for poor people, and for the prevention of famine on failures of the grain-crops. The Royal Society took up this idea, and in 1663 adopted measures for extending the cultivation of the potato, in order to the prevention of famines. To this the example of Ireland in some measure led, the potato having already come into cultivation there to an extent far greater than in any other European country, and with evident advantage to the people. From Ireland the cultivation of the potato was introduced into Lancashire about the end of the 17th century, soon became general there, and thence spread over England; so that before the middle of the 18th century it had become important as a field-crop, which it became in the south of Scotland some twenty or thirty years later, about the same time in Saxony and some other parts of Germany, but not until the later part of the century in some other parts of Germany and in France. In France the potato was long supposed to cause leprosy and fevers, and the extension of its culture was mainly due to the exertions of Parmentier (1778). In Prussia Frederick the Great took an interest in it, and promoted it by compulsory regulations.

The potato is of great importance as affording food both for human beings and for cattle; and next to the principal cereals is the most valuable of all plants for human food. It is also used for various purposes in the arts. No food-plant is more widely diffused; it is cultivated in subtropical countries, and struggles for existence in gardens even within the Arctic Circle, yielding small and watery tubers, although the effects of late spring frosts, or early autumnal frosts, upon its foliage often prove that it is a plant properly belonging to a climate milder than that of most parts of Britain. No more important event of its kind has ever taken place than the general introduction of potato culture into the husbandry of Britain and other European countries. It has exercised a beneficial influence on the general welfare of the people, and has increased the national wealth, notwithstanding the occasional occurrence of famine and distress (notably in the years 1846 and 1847) in Ireland and elsewhere from the failure of the crop. The results—due mainly to excessive and imprudent cultivation of the potato—confirmed two great laws, that plants long very extensively or almost exclusively cultivated in any district, however successfully they may be cultivated for a time, are sure to fail at last; and that the exclusive, or almost exclusive, dependence of a people on one source or means of support is unfavourable to their welfare in respect to all their interests.

Humboldt calculates that the same extent of ground which would produce thirty pounds of wheat would produce one thousand pounds of potatoes. But potatoes are not nearly so nutritious as wheat, and the constant employment of them as the chief article of food is not favourable to the development of the physical powers, and is consequently in its protracted influence unfavourable to mental energy. All this is too well illustrated in Ireland and the Highlands of Scotland, in a race capable of the highest development. It is calculated that 100 parts of good wheat-flour, or 107 parts of the grain, contain as much actual nutriment as 613 parts of potatoes. The inferiority of the potato in nutritious power is very much owing to the comparatively small quantity of nitrogenous substances which it contains, in consequence of which it is most advantageously used along with some very nitrogenous article of food, in Britain generally with animal food, in some parts of Europe with curds or with cheese. The potato tuber, in a fresh state, contains about 71 to 80 per cent. of water; 15 to 20 of starch, 3 to 7 of fibre or woody matter, 3 to 4 of gum, dextrine, and sugar, and 2 of albumen, gluten, and casein. There are considerable differences, however, in different varieties, in different stages of maturity, and in different soils and seasons.

Potatoes are used, both raw and boiled, for the feeding of cattle. For human food they are variously prepared by roasting or boiling, but now chiefly by boiling, a process by which they are freed from all that is narcotic and noxious in their juice. The water in which potatoes have been boiled is not wholesome.

The herbage or haulm of the potato has been used for making paper, but the results were not encouraging. Potato pulp produces a kind of celluloid or vegetable ivory, and from potato-leaves passable or even excellent cigarettes may be manufactured. The berries yield by distillation a tolerable spirit.

The varieties of the potato in cultivation are extremely numerous—500 were exhibited at the Westminster Tercentenary Exhibition (1886). Any enumeration or classification of them is impossible. New ones are continually appearing, and old ones passing away. Those most advantageously cultivated in particular soils and climates are often found to degenerate when removed to a small distance. Potatoes differ considerably in the character of their herbage—which is sometimes erect, sometimes straggling—and in the size and colour of their flowers, but are more generally distinguished by the size, form, and colour of their tubers, which are round, long, or kidney-shaped, white, red, dark purple, variegated, &c.

New varieties of potato are produced from seed; but potatoes are ordinarily propagated by planting the tubers, or cuttings of the tubers, each containing an *eye* or bud. Much has been written by gardeners and agriculturists on the comparative advantages of planting whole tubers or cuttings; but the latter method generally prevails.

Potatoes are planted in drills, made either by the spade or plough, or in *lazy beds*, which are always made by the spade, and are beds in which the sets of potatoes are covered over with earth dug out of the alleys. The alleys serve, although imperfectly, for drains in undrained land. The cultivation of potatoes as a field-crop seems to have been first attempted in lazy beds. They are still common in many parts of Ireland, but are now scarcely ever seen in England or Scotland. They are very suitable for strong, heavy, and somewhat moist land, and are profitably used in reducing some kinds of soil to cultivation, but are generally unsuitable for field-culture, owing to the expense of labour required. In strong, heavy land potatoes are cultivated in raised drills; in lighter and drier soils the raising of the drills is unnecessary. Manure is invariably given, consisting generally of farmyard dung and artificial manures. Common dressings consist of from fifteen to twenty-five tons of dung per acre, with from five to ten cwt. of artificial manure, such as guano, dissolved bones, superphosphate, a little potash, and perhaps nitrate of soda or salts of ammonia instead of guano. The cultivation of potatoes, after they are planted, whether in the field or garden, consists chiefly in keeping the ground clear of weeds, and in earthing up the plants, to promote the formation of tubers. Potatoes are taken up by the fork, by turning over the drills with the plough, or by an implement specially designed for the purpose, known as a potato-raiser. Where the crop is grown extensively this implement is now almost universally used, and performs its work expeditiously and thoroughly. Garden potatoes are generally used long before they are really ripe, forming a favourite dish in a very unripe state, when they are far from being a safe article of food, and contribute not a little to the prevalence of cholera and kindred diseases in summer. In recent years the growing of early potatoes for use in the large towns has been prosecuted to a large extent and with much success on the coast of Ayrshire and other similar parts favoured with a genial climate. To facilitate this the seed is forced in small boxes in which it is placed over winter, and from which it is taken in spring when the shoots are 2 to 4 inches long and planted in well-manured drills. Potatoes from seed thus prepared may be dug about three weeks earlier than if the seed had not been sprouted. The main field-crop is allowed to ripen thoroughly, and is capable of being stored for winter and spring use. The planting of potatoes in the open air cannot be successfully practised in most parts of Britain before February or March, and in many seasons the later-planted are found as early as the earlier-planted, and more productive. The storing of potatoes is variously accomplished in dry lofts or sheds, in airy cellars or barns, and in *pits*, which are sometimes holes excavated to a small depth in the earth, with the potatoes piled up above the surface of the ground, in a conical, or in a roof-like form, sometimes mere heaps of one or other of these forms upon the surface of the ground, and covered with straw and earth to keep out light and frost. Potato-pits should always be well ventilated by means of pipes or otherwise, as without ventilation the potatoes are apt to heat and sprout. Potatoes taken from the ground before they are quite ripe are extremely apt to heat and sprout.

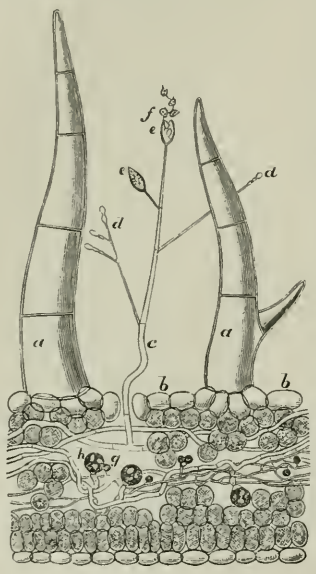
The potato crop is now an important one in almost all the rotations practised in Britain, although its cultivation is in most districts not quite so extensive as before its failure from the *potato disease* in 1845 and subsequent years, and farmers are more careful not to depend too much upon it. It very commonly succeeds a grain-crop, but sometimes is advantageously planted on land newly broken up from grass.

But, besides its value as a culinary vegetable, the potato is important in other respects. Its starch is very easily separated, and is in large proportions; hence it is cheaper than any other kind. It is manufactured on a very large scale. It is chiefly used in textile manufactories under the name of *farina*, which is converted into dextrine or British gum (see STARCH). In Holland and in Russia, where there is much difficulty in keeping potatoes through the winter, and there is consequently a necessity for using the crop quickly, large quantities of starch are made, and this is converted into sugar or syrup (see SUGAR). The refuse of the starch-manufactories is all utilised; it is pressed out from the water,

and used either for pig-feeding or for manure. In the north of Europe much spirit for drinking is made from potatoes; it is called Potato-brandy.

The potato is subject to several diseases, the chief of which is that serious fungous affection now commonly known as the *potato disease*. This disease was first observed in Germany; the earliest known outbreak of a grave character occurred at Liége in 1842. It broke out in Canada in 1844, and at once proved very destructive. In the following year it made its appearance in the British Isles, having been first observed in the Isle of Wight. Its ravages in Ireland in 1846 and 1847 brought a terrible famine upon the small farmers of that country, and at frequent intervals since it has caused great loss in the potato crop.

It has been proved beyond doubt that a particular fungus always accompanies this peculiar and destructive disease. The point is still doubted by some, but it is now very generally believed that this fungus is the main cause of the disease. This mysterious fungus, *Phytophthora infestans*, runs through a strange life-cycle every year, and is by no means easily kept at bay. It is believed that, except in temperatures below 40° and above 77° F., it is always present, ready to pounce upon a weak potato-plant, and liable to develop into an epidemic should the climatic conditions be favourable to fungus-life. These conditions are damp, dull, calm weather, and a moist or wet soil, enveloped in mists morning and evening. The fact that the fungus is unable to bear a temperature above 77° or below 40° is of practical importance. The tomato is also subject to the attacks of the Phytophthora, but the ravages of the fungus may be stopped by raising the temperature of the tomato-house to over 77° F. On the potato crop the fungus generally makes its appearance about the third week in July, almost invariably beginning its attack in the leaves of the potato-plant. There it is first seen in a delicate white bloom, accompanied by dark blotches, caused by the spawn of the fungus having pierced the leaf and set up putrefaction. With favourable climatic conditions it will now develop with great rapidity —a single germ multiplying ten thousand times in a few days in a temperature from 60° to 68° F. The fungus ramifies throughout the leaves, blasting them as it proceeds, and causing an offensive odour which is now unfortunately familiar to the farmer. The spores of the fungus are so light and fine that they float through moist air, and are carried about and spread from one patch of potatoes to another by insects and birds. From the leaves the germs spread to the leaf-stalks, the stems, and the tubers. The spawn readily pierces the skin of the tuber, consuming or rotting the cells, and corroding the starch, and ultimately reducing the potato to a black mass of rottenness. In this last stage of its yearly course of destruction the fungus provides means of continuing its curious life. It produces some kind of 'resting-spores,' which, possessed of amazing vitality, lie dormant during winter and spring, and carry on the disease to the crop of the succeeding year, which in its turn passes the fungus through another round of its mysterious life, to be handed on again from crop to crop as before. There is still uncertainty as to the precise character of these spores; but, be what they may, their tenacity of life is great.



Section of potato leaf, lower surface uppermost, showing *a,a*, hairs of the plant; *b,b*, epidermal cells; *c*, hydra, or thread of the fungus *Phytophthora infestans; d,d*, conidia or bud spores; *e,e*, zoospores; *f*, zoospore bursting to liberate the zoogonidia; *g*, antheridia or male portion, and *h*, oogonia or female portion, of a fungus in the central tissue of the leaf, but whether portions of the Phytophthora, as once asserted, or of another fungus, Pythinur, is doubtful (*Gardener's Chronicle*, 1891).

Of the many remedial measures that have been tried, the following have been found most useful in preventing or mitigating the onslaught of the fungus: (1) Earthing up the drills with a deep covering of earth, with the view of preventing the fungus from passing down the stem, or through the soil to the tubers; (2) cutting off the diseased potato-tops before the fungus reaches the tubers; (3) removing and burning all dead and decaying potato stems, leaves, and tubers, especially after a crop which has been attacked by the disease; (4) planting varieties which have been known to be exceptionally successful in resisting the disease; (5) growing the potato crop under such general cultural, sanitary, and manurial conditions as will ensure to the fullest extent possible the healthy and vigorous development of the crop; (6) careful selecting and storing of potatoes to be used as seed; and (7) dressing the potato-tops, both before and after the appearance of the disease, with sulphate of copper. No certain prevention or absolute remedy has as yet been discovered, but all these measures have been carried out with advantage. The discovery of the copper remedy is likely to be of great importance to potato growers. This is the mixture—about 3 to 6 parts of sulphate of copper and quicklime to 100 parts of water—which proved so effectual in combating the allied parasite fungus, *Peronospora infestans*, that attacks the vines, and there is good reason to believe that it will be almost equally successful in averting the potato disease. It is well known that a vigorous variety of potatoes grown under conditions favourable to its healthy development is most successful in resisting the fungus. It is with the potato as with a human being—deprive it of wholesome food and healthy sanitary surroundings, and disease will speedily ensue. The prevalence of this particular disease in recent years is a sure indication of a deterioration in the constitutional vigour of the cultivated potato. The other diseases from which the potato crop is liable to suffer are *Curl*, *Scab*, *Dry Rot*, *Wet Rot*, and a fungus known as *Peziza postuma*. *Curl* is a disease affecting the foliage and general health of the potato-plant, and does not seem to be necessarily connected with the presence of any vegetable parasite or insect enemy.—*Scab* is a disease of the tubers, which become covered with brown, oblong, and finally confluent and cup-shaped spots, whilst under the surface is a powdering of minute olive-yellow grains, a fungus called *Tubercinia scabies*, of the division Hyphomycetes.—*Dry Rot* is also ascribed to the growth of a fungus of the same order, *Fusisporium solani*, and attacks the tubers either when stored for winter or after being planted. It was first observed in Germany in 1830, and caused great loss in that country throughout many years. The tissues of the potato-tuber become hardened and completely filled with the mycelium

of the fungus, which at last bursts forth in little cushion-shaped tufts loaded with fructification.—*Wet Rot* differs from dry rot in the tubers becoming soft and rotten instead of hard and dry, and is always characterised by the presence of a fungus referred by Fries to his genus Periola, but which Berkeley regards as another form or stage of the same fungus which causes or is inseparably connected with dry rot. Both dry rot and wet rot have often been observed along with the *potato disease*, which, however, is always characterised by the presence of another peculiar fungus.—*Peziza postuma* has occasioned heavy losses, chiefly in Ireland, by destroying the leaves before the crop has matured. See books on potato-culture by Pink (1879), Cox (1880), Fremlin (1883), and Ward (1891), and on the potato-blight by Bravender (1880).

Potato, Sweet. See Sweet Potato.

Potato-beetle. See Colorado Beetle.

Potato-fly (*Anthomyia tuberosa*), a dipterous insect of the same genus with the Radish-fly, Cabbage-fly, Turnip-fly, &c. In its perfect state it is very like the House-fly. The maggots are often abundant in bad potatoes in autumn, and are different from the maggots of the House-fly, being horny, spiny, bristly, and tawny; the long tail ending in six long bristles. The pupa is very like the larva.

Potato-fly (*Anthomyia tuberosa*):
1, Larva, or maggot, natural size;
2, larva magnified; 3, Potato-fly.

The Potato-frog Fly (*Euteryx solani*, Curtis) and the caterpillar of the Death's-head Moth (*Acherontia atropos*, Linn.) feed on the leaves and stems of potatoes, but rarely do serious damage.

Potchefstroom, a town in the south of the Transvaal, South Africa, 105 miles SW. of Pretoria. Pop. 2000.

Potemkin, Gregory Alexandrovitch, the most celebrated of the Empress Catharine II.'s favourites, was born near Smolensk on 16th September 1739, the descendant of a noble but impoverished Polish family. Having entered the Russian army, he managed (1762) to attract the notice of the czarina by his handsome face and athletic figure; he was attached to her household, and in 1774 was preferred as her recognised favourite. From 1776, when the Emperor Joseph of Austria made him a prince of the Holy Roman Empire, till the year of his death he was the director of the Russian policy in Europe. It was at his instigation that the khan of the Crimea put himself (1783) under Russian protection. Four years later Catharine paid a visit to his government in the south, and the 'hoax' which he then played off on his sovereign is described by De Ségur (*Mémoires*). He caused an immense number of wooden painted houses to be constructed, and grouped into towns and villages along the route the czarina was to take, and hired people to act the part of villagers, merchants, tradesmen, and agriculturists, engaged in their various pursuits. The czarina's vanity was hugely gratified at the seeming improvements of the country under her rule, and she covered Potemkin with titles and honours. Almost immediately after this a war broke out with the Turks, and Potemkin was placed at the head of the army, with Suwaroff serving under him. Otchakoff was taken after a terrible siege, and Suwaroff won the great fights of Bender and Ismail—of all of which Potemkin reaped the credit when he entered St Petersburg in triumph in 1791. That same year he was seized with sudden illness whilst travelling between Jassy and Otchakoff, and died October 15, and was buried at Kherson. He was a man of considerable ability in court intrigue and statesmanship; his skill as a general has been both affirmed and denied. Personally he was licentious, coarse in his habits, and utterly tyrannical and unscrupulous; in spite of his lavish extravagance he heaped up an immense fortune.

See *Memoirs* (Lond. 1812), and the Life in German by his secretary Saint-Jean (new ed. Karlsruhe, 1888).

Potential, in dynamical science, is a quantity of peculiar importance. Its value, as a mathematical function in the theory of attraction, was recognised by Laplace in the *Mécanique Céleste*. The name was, however, given by George Green (1793–1841) in 1828, when its broad dynamical significance was for the first time explicitly stated and powerfully developed. The theory of the potential, in fact, is co-extensive with the dynamics of what are known as *Conservative* systems. When such a system is made to pass from one configuration to another, the work done against the forces of the system depends only upon the initial and final configurations, and in no way upon the particular series of changes by which the passage is made. For instance, the work done against gravity in lifting a given mass to a height of 500 feet is exactly the same whether the mass is lifted vertically up, by a balloon, say, or more laboriously taken up the gentle slope of a hill. The earth and the mass form, so far as gravitation is concerned, a conservative system. Practically, however, in dragging a mass up a slope a certain amount of work, greater or smaller according to circumstances, must be done against friction, and this will depend upon the character of the course taken. We know that the work so done is lost and cannot be recovered in dynamic form (see Energy). These forces are in short dissipative, and so far as their action is concerned the system is not conservative, and the theory of the potential does not apply. A little consideration will show that when the forces are functions of distances only the system will be conservative. Such forces then have a potential; and, although this does not exhaust all types of force-systems which have a potential, it includes all that are certainly known to occur in nature around us. The force of gravitation and the force between electrified or magnetised bodies evidently belong to the category just described. In all such cases the potential at any point in the field of force is a definite function of the position, a mathematical expression having for any particular case a definite value, such that the difference of the potentials of two points measures the work done in carrying unit quantity (of matter, electricity, magnetism, &c.) from the one point to the other (see Electricity for some further properties of the potential). If we take the two points very close to each other, we see at once that the small difference of the potentials must equal the product of the average force into the corresponding small distance. Thus, in the notation used in the article Calculus (q.v.), we have $\Delta V = S \Delta s$, where V is the potential, S the force, and Δs the small distance. Hence $S = dV/ds$ or the force in any direction is numerically equal to the rate of change of the potential per unit-length in that direction. When the potential is known a simple

differentiation in any chosen direction gives the force in that direction. It is obvious that other directed quantities besides forces may be expressible as the differential coefficients of a single non-directed or scalar quantity. Thus, in the mathematical theory of Hydrodynamics (q.v.) a very important distinction is made between motions which have a velocity-potential and motions which have not. In the former the velocity can be represented as a space differentiation of a scalar quantity; in the latter it cannot. See VORTEX for an account of fluid motion, which has no velocity-potential.

Potentilla, a genus of plants of the natural order Rosaceæ, sub-order Potentilleæ, differing from Fragaria (Strawberry) in the fruit having a dry instead of a succulent receptacle. The species are very numerous, natives chiefly of northern temperate regions, and some of them of the coldest north; most of them perennial herbaceous plants, with yellow, white, red, or purple flowers, and pinnate, digitate, or ternate leaves. They are often called Cinquefoil (Fr., 'five-leaved'); and some of the species are favourite garden flowers. A few are natives of Britain; one of the rarest of which is a shrubby species (*P. fruticosa*), forming a large bush, with pinnate leaves, and a profusion of yellow flowers, often planted in shrubberies. *P. reptans*, a common British species, with creeping stems, digitate leaves, and yellow flowers, once had a high reputation as a remedy for diarrhœa, from the astringent property of its root, of which most of the species partake with it. But *P. anserina*, a very common British species, popularly known as Silverweed, having creeping stems, yellow flowers, and pinnate leaves, which are beautifully silky and silvery beneath, has an edible root, with a taste somewhat like that of the parsnip. Swine grub it up with avidity, and it was once much esteemed as an article of food in some parts of Scotland, particularly in the Hebrides, where it abounds and has been a resource in times of famine. —The name potentilla is said to be derived from the Latin *potens*, 'powerful,' and to allude to medicinal virtues now known to merit little regard. Tormentil (q.v.) is sometimes referred to this genus.

Potenza (anc. *Potentia*), a town of South Italy, ensconced in a valley of the Apennines, 103 miles E. by S. of Naples. It is surrounded by a wall, has a fine cathedral, and disused fortifications. Potenza was shaken by earthquakes in 1273, 1694, 1812, and 1857. Pop. 17,978.—The *province* of Potenza, called Basilicata until 1871, has an area of 3998 sq. m. and (1889) a pop. of 556,309.

Pot-herbs are not, as might be supposed from the name, the vegetables chiefly used for culinary purposes, as supplying articles of food, but rather those which are of secondary importance, and valuable chiefly for flavouring, as parsley, fennel, &c.

Pot-holes. See GIANTS' KETTLES.

Poti, a seaport of Russian Caucasus, stands at the mouth of the river Rion, on the eastern shore of the Black Sea, 200 miles by rail W. of Tiflis. Here maize (£242,000), manganese (£85,000), &c. are shipped to the annual value of £366,000. The imports do not exceed £2000. Poti was seized by Russia in 1828. Pop. 3112.

Potidæa, a Corinthian colony founded on the westernmost isthmus of the Chalcidice peninsula in ancient Macedonia. By its revolt from the Athenian League (432 B.C.) it brought on the Peloponnesian war; it was besieged and taken by the Athenians (429 B.C.). The Athenian colony which was then settled there was destroyed by Philip of Macedon (356 B.C.). Cassander built up a new town, and called it Cassandria; this flourished greatly until it was captured and sacked by the Huns.

Pot-metal. Tap and pot metals are alloys of copper and lead. The proportions of the two metals vary from equal parts of each to 1 of copper and 10 of lead.

Poto'mac, a river of the United States, formed by two branches which rise in the Alleghany Mountains in West Virginia, and unite 15 miles SE. of Cumberland, Maryland, from which point the river flows in a generally south-easterly course 400 miles, and falls into Chesapeake Bay, after forming an estuary nearly 100 miles long, and from 2½ to 7 miles wide. The largest ships can ascend to Washington, and the tide reaches Georgetown. A few miles above Washington the river forms a cataract 35 feet high; and between there and Westport it falls more than 1000 feet. The scenery in this portion of its course is wild and beautiful, especially where it breaks through the Blue Ridge at Harper's Ferry. Its principal affluents are the Shenandoah, Cacapon, and Monacacy. The Potomac forms the greater part of the boundary between Virginia and Maryland.

Potoroo, or KANGAROO RAT (*Hypsiprymnus*), a genus of marsupials, related to kangaroos. None of the species are larger than rabbits. They feed on roots, for which they dig with their fore-feet. Two other genera, Bettongia and Æpiprymnus, are nearly related.

Potosí, capital of a department of the same name, and one of the most famous mining-towns of South America, stands in a dreary and barren district, nearly 50 miles SW. of Chuquisaca. It is built on the side of the Cerro de Potosí (15,381 feet), at an elevation of 13,000 feet above the sea, and is thus one of the loftiest inhabited places on the globe. The town has a circumference of some 4 miles; but fully one-half is composed of tottering and ruined buildings, uninhabited and desolate, and the whole place, with its squalor, dilapidation, and dirt, presents a sinister aspect. The public buildings include a handsome cathedral and a mint which employs 200 hands; and the reservoirs are also worthy of mention. The streets are steep and narrow, and there are no wagons or carriages, but only llamas and mules. The climate is very trying: all the four seasons may be experienced in one day, but usually it is bitterly cold, owing to the elevation and to the mountains all round, from which the snow scarcely ever melts. Yet is Potosí one of the principal commercial towns of Bolivia. English and French manufactures are imported; and, as the country in the vicinity produces little or nothing, all supplies have to be brought from a distance. The industry of the place is limited to silver-mining. The Cerro is still rich in this ore, although the production, owing to the exhaustion of the mines near the summit, and the frequent inrush of water in those worked at a lower level, has greatly fallen off. Potosí was founded in 1545, and in 1611 had 160,000 inhabitants. Its population does not now exceed 12,000.—The *department*, a plateau country, rich in minerals and cattle, has an area of 54,300 sq. m. and a pop. (1892) of 360,400. It is second in pop. of the Bolivian departments.

Pot-pourri (Fr.), the name of a mixture of sweet-scented materials, chiefly flowers, dried, and usually placed in a vase with a perforated lid, in order that their perfume may be diffused through rooms in which it is placed. The principal ingredients are rose-petals, lavender flowers and stalks, violets, jessamine-flowers, woodruff-leaves, cloves, orris-root, pimento, musk, sandalwood-raspings, cedar-shavings, &c. But it also, and originally, signifies a dish of different sorts of viands, and

corresponds in this sense to the *Hotch-potch* (q.v.) of Scotland and the *Olla Podrida* (q.v.) of Spain. In Music the name is used for a selection of popular pieces strung together without much arrangement—a kind of medley.

Potsdam, chief town of the Prussian province of Brandenburg, and second residence town of the royal family of Prussia, is situated on an island beside the lake-like river Havel, 18 miles by rail SW. of Berlin. It is a handsome city, with broad streets, public gardens, adorned with statues of Prussian soldiers, and fine squares. The royal palace (1667–1701), in the park of which are statues of Frederick-William I., Alexander I. of Russia, and Generals Blücher, Gneisenau, Kleist, and Tauenzien; the town-house, a copy of that at Amsterdam; and the military orphanage are the finest of the public buildings. The garrison church, with a steeple 290 feet high, contains the tombs of Frederick-William I. and Frederick II.; and the Friedenskirche the tombs of Frederick-William IV. and the Emperor Frederick III. The Brandenburg Gate is a copy of Trajan's Arch at Rome. In the immediate neighbourhood of the town are more than half-a-dozen royal palaces, as Sans-Souci (1745–47), the favourite residence of Frederick the Great, surrounded by a splendid park and gardens, containing Rauch's monument to Queen Louisa and other structures; the palace of Friedrichskron, formerly the New Palace (1763–70), with nearly 200 rooms, many of which contain costly works of art; Charlottenhof, built by Frederick-William IV. in 1826; the Marble Palace, the summer residence of the Emperor William II.; and Babelsberg, the private property of the same prince. Potsdam has an observatory, and a cadet and other military schools. Its manufactories produce sugar, chemicals, harness, silk, waxcloth, beer, &c. Flower-gardening, especially of violets, is a busy industry. Alexander von Humboldt was a native. Pop., including the garrison (1890), 53,727. Potsdam owes its creation as a town to the Great Elector, Frederick-William, and to Frederick II. Prior to that period it was a fishing-village, built on the site of an ancient Slav settlement. See German works by Kopisch (1854), A. R. (1883), and Sello (1888).

Potsdam Beds, a name given in North America to the uppermost division of the Cambrian or Primordial strata.

Potstone, *Lapis Ollaris* of the ancient Romans, a massive variety of talc-schist, composed of a finely-felted aggregate of talc, mica, and chlorite. It is generally of a grayish-green colour, sometimes dark green. It occurs massive, or in granular concretions. It is soft and easily cut when newly dug up, greasy to the touch, and infusible even before the blowpipe. It becomes hard after exposure to the air. It is made into pots and other household utensils, which communicate no bad taste to anything contained in them, and when greasy are cleaned by the fire. It was well known to the ancients; and Pliny describes the manner of making vessels of it. It was anciently procured in abundance in the isle of Siphnos (Siphanto), one of the Cyclades, and in Upper Egypt. Large quarries of it were wrought on the Lake of Como, from about the beginning of the Christian era to 25th August 1618, when they fell in, causing the destruction of the neighbouring town of Pleurs, in which it was wrought into culinary vessels, slabs for ovens, &c. It is quarried in the Valais, Moravia, Norway, Sweden, Greenland, near Hudson Bay, &c.

Pott, August Friedrich, a great philologist, was born at Nettelrede in Hanover, 14th November 1802. He studied philology at Göttingen, habilitated at Berlin in 1830, in 1833 became extraordinary, in 1839 ordinary professor of the Science of Language in the university of Halle. Next to W. Humboldt, Bopp, and Grimm, the name of Pott stands prominent in the new science of comparative philology. The foundation of Pott's reputation was securely laid by his *Etymologische Forschungen auf dem Gebiet der Indogermanischen Sprachen* (2 vols. 1833–36; 2d ed. 6 vols. 1859–76), a work second in importance only to Bopp's *Comparative Grammar*. His well-known article 'Indogermanischer Sprachstamm,' in Ersch and Gruber's *Encyklopädie*, is a masterpiece of condensation, and for once of order. For his besetting fault was a lack of order and perspicuity, which made Ascoli compare his books to the plain of Shinar after the confusion of Babel had taken place. But no student ever brought to his studies a loftier spirit of devotion, or collected more massive materials for the foundation of a new science. So thorough was his treatment that all the progress of learning since has not stripped the value from his books on the Gypsies, on Personal Names, on Numerals, his essays on Mythology, African Languages, or General Grammar. He died at Halle, 5th July 1887, working to the last.

His most important books, besides those already named and countless articles and papers in the learned journals, are *De Borussico-Lithuanicæ tam in Slavicis quam in Letticis Linguis Principatu* (1837–41); *Die Zigeuner in Europa und Asien* (2 vols. 1844–45); *Die Quinare und Vigesimale Zählmethode bei Völkern aller Weltteile* (1847); *Die Personennamen* (1853); *Die Ungleichheit der menschlichen Rassen, hauptsächlich vom Sprachwissenschaftlichen Standpunkt* (1856); *Doppelung als eins der wichtigsten Bildungsmittel der Sprache* (1862); *Anti-Kaulen, oder mythische Vorstellungen vom Ursprung der Völker und Sprachen* (1863); and *Die Sprachverschiedenheit in Europa, an den Zahlwörtern nachgewiesen* (1868).

Pottawattamies, a tribe of American Indians, belonging to the Algonquin stock. The early French settlers established a mission amongst them at Green Bay, and to this day many of them are Roman Catholics. They sided with the English both during the Revolution and in the war of 1812, and afterwards settled in Kansas, where one band of over 400 now live in houses and cultivate the ground. Another band, nearly 500 strong, is on a reservation in the same state, under the care of the Society of Friends.

Potter, John, D.D., an English scholar and divine, the son of a linen-draper of Wakefield, in Yorkshire, was born in 1674, studied with great diligence and success at Oxford, where he took his degree of M.A. in 1694, and in the same year received holy orders. He was appointed chaplain to Queen Anne in 1706, professor of Divinity at Oxford in 1708, Bishop of Oxford in 1715, and finally in 1737 attained the highest dignity in the English Church—the archbishopric of Canterbury. He died 21st October 1747, and was buried at Croydon. Potter's principal work is his *Archæologia Græca* ('Antiquities of Greece,' 2 vols. 1698), not superseded until the appearance of Dr W. Smith's *Dictionary of Greek and Roman Antiquities;* besides which, however, we may mention his edition of *Lycophron* (1697) and of *Clemens Alexandrinus* (1715).

Potter, Paul, the greatest animal-painter of the Dutch school, was born at Enkhuizen in 1625, and was the pupil of his father, Pieter Potter, a landscape-painter, with whom in 1631 he came to Amsterdam. He was also an excellent etcher, and so precocious that his best etched pieces, 'The Herdsman' and 'The Shepherd,' were finished in 1643 and 1644 respectively. He established himself at the Hague in 1649, where next year he married the daughter of an architect, but in 1653 he returned to Amsterdam. He died there in January 1654 at the untimely age of twenty-nine. His

best pictures are pastoral scenes with animal figures, the life-size 'Young Bull' (1647, at the Hague) being especially celebrated. His 'Dairy Farm,' measuring only 19½ by 48½ inches, was sold in London on 27th June 1890 from the Stover collection for £6090, or £13 per square inch. The Rijks Museum at Amsterdam possesses the 'Bear-hunt' and seven other pictures from his easel. Very many of his productions are preserved in England.

See *P. Potter, sa Vie et ses Œuvres*, by Van Westrheene (the Hague, 1867), and Cundall, *Landscape Painters of Holland* ('Great Artists' series, 1891).

Potteries, The, a district in North Staffordshire, 9 miles long by 3 broad, the centre of the earthenware manufacture in England, includes Hanley, Burslem, Stoke-upon-Trent, Newcastle-under-Lyme, Tunstall, and other towns.

Pottery. This term, derived through the French *poterie* from the Latin *potum*, 'a drinking vessel,' is applied to all objects of baked clay. Pottery may be said to be almost contemporaneous and co-extensive with mankind; it is found with the remains of our remotest ancestors, and it is fashioned amongst the rudest of present day tribes. The art in its rudimentary condition—merely moulding wet clay into the desired form, and submitting it to the hardening heat of the sun or of fire—is so simple as to be within the capacity of the least tutored savage. The universality of the primitive art, and the many different lines along which it progressed, preclude the possibility of tracing its history in chronological sequence, and only a few of its more important developments can be noticed in the historical section.

Pottery as known at the present day is distinguished into many classes according to the nature and purity of the clay employed, the heat to which it has been exposed in firing, the glazes or enamels with which it has been covered, and the coloured or other ornamental treatment of its surface. Briefly, as regards material and baking it may be divided into (1) earthenware, which, exposed to a comparatively low heat, remains earthy in texture and can be scratched with a steel point; (2) stoneware, fired at a high heat, hard, dense, compact, and not scratched by the knife; and (3) porcelain, fired at the highest temperature, semi-fused and vitreous in structure, and, when sufficiently thin, translucent. Earthenware again may be subdivided according to the manner in which its surface is treated, being either (1) plain, as in an ordinary flowerpot; (2) lustred, as in the black surfaced pottery of ancient Greece; (3) glazed or coated with a transparent glass or varnish; and (4) enamelled or coated with an opaque white or coloured glass, which completely conceals the body over which it is spread.

Manufacture.—The dough-like condition into which clay can be worked with water, and the hardness and indestructibility it acquires by burning, are the qualities upon which the potter's art essentially depends. Clay is one of the most abundant of substances, but it is of many qualities and degrees of purity. The commonest brick clays are so coarse in texture and so impregnated with iron and other foreign ingredients that they can be used only for bricks, tiles, and the very coarsest kinds of pottery. The purest potters' clay, known as china-clay or Kaolin (q.v.), is formed by the decomposition of granitic rocks. It consists essentially of the hydrated silicate of alumina with small proportions or traces of one or more of lime, potash, soda, and magnesia. The finest china-clay of Great Britain is found in Cornwall, where it was discovered at Carclaze, 2 miles NE. of St Austell, between 1755 and 1758 by William Cookworthy. Cookworthy's discovery was of the utmost importance for the home manufacture of porcelain and fine pottery; and the development of the industry which took place under Josiah Wedgwood and others was due in no small measure to the fine material which thus became available to them. Commoner potters' clay or pipeclay is obtained principally from Poole in Dorsetshire. The materials used for the paste or body of typical varieties of porcelain and pottery are as follows: (1) *Porcelain.*—At Sèvres, kaolin, 48 parts; sand (pure white), 48 parts; chalk, 4 parts. At Dresden, kaolin, 62 parts; felspar, 26 parts; broken biscuit-porcelain, 2 parts. At Berlin, kaolin, 76 parts; felspar, 24 parts. In England three mixtures are used: for common china, ground flints, 75 parts; calcined bones, 180 parts; china-clay, 40 parts; clay, 70 parts. For fine china, ground flints, 66 parts; calcined bones, 100 parts; china-clay, 96 parts; Cornish granite, 80 parts. Fine, for modelling figures, &c., Lynn sand, 150 parts; calcined bones, 300 parts; china-clay, 100 parts; potash, 107 parts. The glazes require to be varied for nearly all, so that their fusibility may be greater or less, according to the more or less fusible character of the biscuit ingredients. (2) *Stoneware*, such as is used for jars, bottles, drain-pipes, &c., is made of several kinds of plastic clay, mixed with felspar and sand, and occasionally a little lime, but the materials vary much in different localities. (3) *Earthenware*, called also *Faience* or *Delft*, is made of various kinds of clay, varying in colour from yellow to white, according to the quality required; and more or less of powdered calcined flints are mixed with it, to give it body and hardness. Sometimes, as in porous vessels, only clay is used.

The use of calcined flint was first adopted by a Burslem potter named John Astbury, who in 1720 noticed the fine white character of a powder applied to the eyes of his horse for the cure of some ailment. He learned that the powder was made from calcined flint, and thereon he conceived the idea of using it in his pottery; and did so with great success. The ingredients, such as the clay and calcined flints, are prepared by separate means, the former in the pug-mill, which is represented in fig. 1. This is an upright, iron-bound, wooden cylinder, with an axis, A, turned by machinery; projecting from A are seven arms, *b*, each of which has three knives fixed in it, with the points outward, and so arranged that they spread over the largest amount of space in the interior; and altogether they are placed in a spiral manner, so that when in motion the clay, which is thrown in lumps into the hopper-shaped upper part of the vat, is worked down, and is so cut and kneaded by the knives that it is forced out at an opening at C in the state of soft pap. This is aided by the knives on the lower part of the lowest arm being connected together by a plate, D, which prevents all settlement at the bottom. This pap-like clay passes into a large wooden tank, in which it is agitated with water until quite incorporated, so as to resemble milk in colour and consistency. In another mill (fig. 2), of

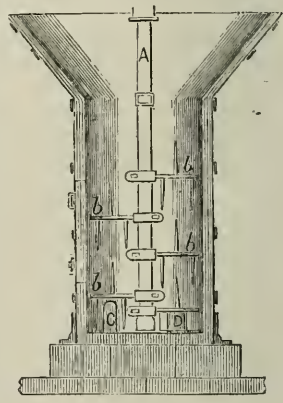


Fig. 1.

a different construction, the Cornish granite and calcined flints are reduced to a somewhat similar state. This mill is very strongly constructed, and consists of a tub-like vat, A, in the centre of which turns an axle, B, moved by machinery; in the bottom of the vat is a thick stone-bed, C, consisting of either chert or horn stone. From the upper part of the axis three strong arms, D, D, D, project like the spokes of a wheel; and strongly attached to these are stout beams, *a*, pointing downward, and nearly touching the stone-bed, C. As the axis, with its arms and beams, turns round, the beams push some large masses of the Cornish granite or of chert stone round with them, and these triturate the calcined flints and other hard materials, and

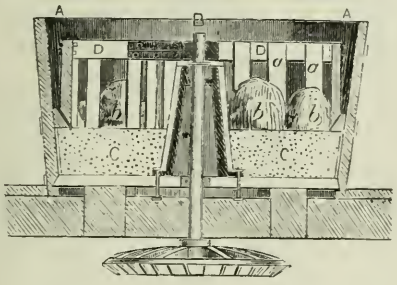

Fig. 2.

stir up the water with which the vat is kept constantly supplied, whilst it overflows in a milky state, charged with the finely-divided materials, into a cistern, where it is kept stirred until it is sufficiently supplied with the solid materials, and the thickened milky liquid is then drawn off, in proper proportions, into a vat to which the prepared clay is also passed. The mixture of the two is then allowed to subside until the water is nearly clear, when it is drawn off; and the sediment is deprived of its surplus moisture, either by evaporation, or, in the best works, by a pneumatic exhausting apparatus, which does it very quickly. The composition is then a fine plastic material of the consistency of tough dough, and is ready for the potter's use. In preparing the finer materials for porcelain many other operations are required, all, however, having the same object—viz. the extremely minute division of the substances used.

The prepared clay is taken to the *throwing-machine*, or *potter's wheel*, which is represented in fig. 3. This consists of a fixed table, A, through

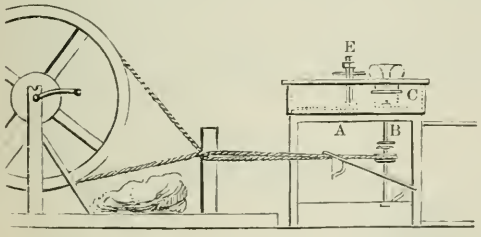

Fig. 3.

which passes the axle, B, and rises a little above its surface, and having on its upper end a disc, C, which revolves with it. The axle is put into rapid motion by turning the fly-wheel, D, either by hand or machinery; and this causes a rapid revolution of the disc, C, upon which is placed the soft mass of clay to be moulded. At E is seen an upright, with a small sliding-bar regulated by a screw; this is the guide for the potter to regulate the height of the vessel he is making. When the lump of clay is revolving, the potter, with his hands or with proper tools, fashions it into any rounded form he desires, gradually working from the base upwards till the vessel in his hands attains the external shape, height, and thickness of wall required. It is then put aside for some time to dry, and when in a state of greatest doughy tenacity it is fixed on a turning-lathe, and by means of sharp steel tools its surface is accurately turned and smoothed. But some articles are formed in moulds, the moulds being made of plaster

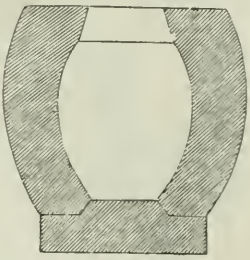

Fig. 4.

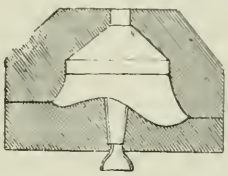

Fig. 5.

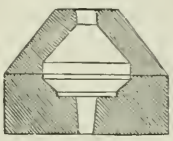

Fig. 6.

of Paris. This answers well for fine porcelain intended to be very thin, because the plaster-mould absorbs much of the moisture in the paste, and thus partially dries it, so that it admits of handling, which in a softer state would be very difficult. The paste is used so liquid that it can be poured into the moulds. It is usual, in casting, to have a mould for each part, as seen in figs. 4, 5, 6, which represent the body, neck and lip, and foot of the cream-ewer, fig. 7. The handle is also separately moulded, and attached with the aid of a fluid clay paste, called a slip. For nearly flat articles, such as dinner-plates, a plan is adopted which combines both processes: a mould, usually of plaster, fig. 8, *a*, is placed on the disc of the throwing-wheel, *b*, and a thin

Fig. 7.

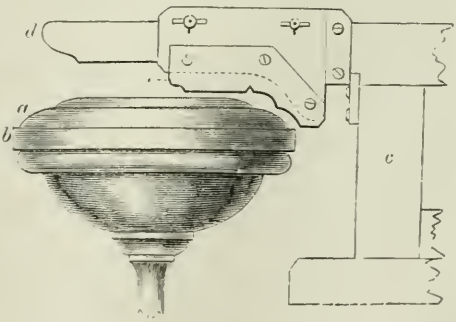

Fig. 8.

layer of the paste is pressed on to it, so as completely to take its form; then to the guide-post, *c*, is attached an arm, *d*, with a small brass plate,

e, on its lower side. This plate is cut to the outline of half the plate, or dish; as it revolves, this pares down and shapes the clay to its own outline, and to the thickness to which it is set, there being an arrangement on the arm of the guide-post by which this can be effected. Sometimes, as in the case of deep vessels, moulds are used for the exterior, and the interior is formed by the hand. This process (fig. 9) ensures certainty of size and shape, which is important in making large numbers of similar articles, as tea-cups, &c. The mould is lined with a thin cake of clay, and when placed on the revolving disc it is fashioned inside by hand, and finished off with a wet sponge. Sometimes metal or horn tools are used for producing mouldings and other raised ornaments, or for grooves, when the turning or throwing wheel is used.

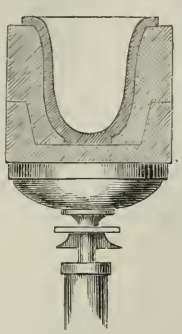

Fig. 9.

Being formed, the articles, of whatever kind, are now taken to the drying-stove, where they are placed on shelves, and remain there some time, exposed to a heat of about 85° F. When quite dry, they are next taken to a workshop near the kiln, and they are here carefully packed in coarse earthenware vessels, called *seggars* (fig. 10), which are so made that they can be piled upon one

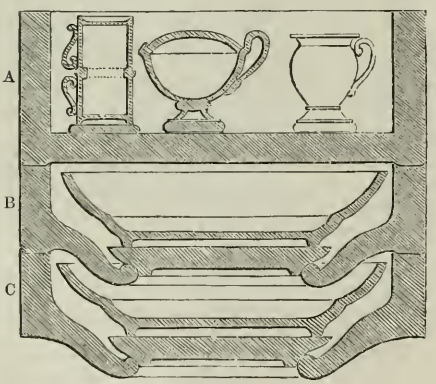

Fig. 10.

another to a great height in the kiln, as seen in fig. 11, in which some of the seggars are shown in section, for the purpose of making the arrangement intelligible. As the seggars are generally made large enough to hold a number of articles, which would, when highly heated, adhere if they touched, a number of curiously shaped pieces of burned clay are used for placing between them, so as to make them rest on points; these are called *watches*, *cockspurs*, *triangles*, *stilts*, &c. (fig. 12). In the seggar filled with plates (fig. 13) the plates are seen each resting on *cockspurs*, which prevent them touching. Another object is gained by this in burning flat articles such as plates; these, if placed one upon another, would not be fired equally, but when they are held apart the heat affects all parts alike. The seggars are so piled in the kiln that the centre is hollow, and there are free spaces between them through which the fire can ascend; props, *a*, *a*, *a*, fig. 11, being so placed as to keep them from immediate contact with the sides all round. Thus each seggar forms a small oven, in which one or more pieces of pottery or porcelain are baked, and the seggars prevent any unequal heating of the pieces, and also protect them from smoke. A kiln has generally eight furnaces, and it is usual to raise six piles of seggars between every two furnaces, or rather between their flues, which rise to a considerable height in the kilns. Each pile of seggars is technically called a *bung*, so that there are generally forty-eight or fifty bungs to the charge of a kiln. When all this is arranged the furnaces are lighted, and great care is taken to

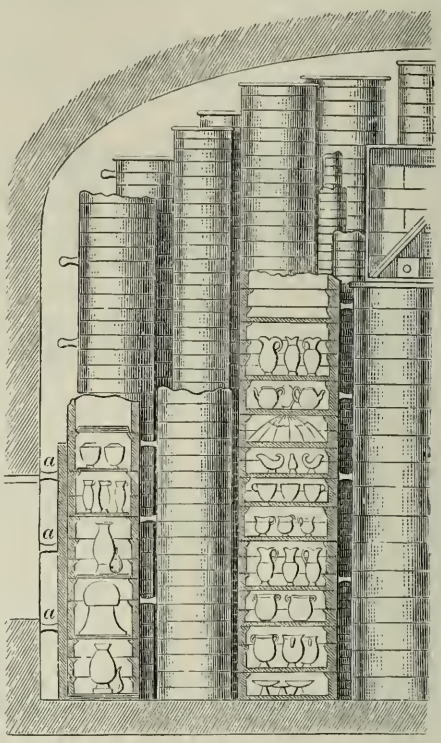

Fig. 11.

use the best coal, as it enables the manufacturer to make a more certain calculation as to its effects, and is less liable to smoke and sulphurous vapours, which might injuriously affect the contents of the kiln. The baking or firing usually lasts from forty to forty-two hours. The fire is then allowed to go out, and the kiln to cool very gradually, after which it is opened, and the seggars removed, to be unpacked in a separate workshop.

The articles are now in the state called biscuit-ware, and are ready for any pattern they may be intended to bear, and the glaze. Here, however, it may be stated that it is possible to glaze refractory pottery, such as stoneware in the biscuit oven, and

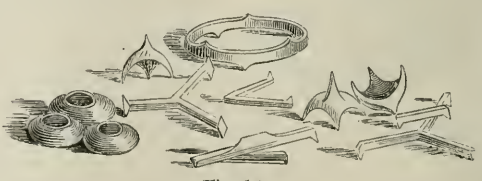

Fig. 12.

thus avoid the necessity for two firings to the ware. The glazing is in this case effected by throwing common salt into the oven when at its highest temperature. The salt is volatilised and the sodium separates from the chlorine, and, combining with the silica it finds in the heated ware, forms a

true soda glass with it, which makes a uniform transparent glazed layer over all the pottery surfaces which it reaches. In this way all glazed sanitary wares and ordinary stoneware jars and bottles are made at one firing. Common pottery is often figured by printing the design in enamel colours on transfer-paper, and, whilst the printing is still wet, applying it to the biscuit-ware; the ware absorbs the enamel ink, and the paper is removed by water, leaving the pattern on the ware. It is next fired in seggars, or a muffle, to fix the colour, and is then dipped into composition called *glaze*, of which three kinds are used in the Staffordshire potteries. The first, for common pipeclay ware, is composed of Cornish granite, 16 parts; flint, 36 parts; white-lead, 53 parts; and cullet, or broken flint-glass, 4 parts. These materials are triturated with water, with the same care and by similar means to those employed in forming paste, and are reduced with water to the same milk-like liquidity. Each workman has a tub of the glaze before him; and as the articles of biscuit-ware, either with or without decorations, are brought to him, he dips them in the glaze, so as to ensure a uniform coating over them; and by nice management he prevents any large drops or accumulations on one part more than another. The porous biscuit-ware rapidly absorbs the moisture, and dries up the thin film on the surface of the articles, which are again placed in seggars, and carried to the glaze-kiln, where they undergo another firing, which melts the glaze, and converts it into a transparent glass all over the surface, and renders any pattern previously printed upon it very plain. The temperature in the glaze or enamel kiln is only increased very gradually, and is kept up for about fourteen hours, after which it is allowed to cool slowly, and the articles are taken out completed. So far, this description has applied to the manufacture of pottery and porcelain on a large scale, for general purposes; but when it is applied to more costly and artistic works very special arrangements are required; and in the case of remarkably fine pieces, instead of the huge kilns, which hold frequently many thousand pieces, muffle furnaces (fig. 14) are used for each separate article for the biscuit, the glaze, and the coloured and gilded decorations, which, in porcelain, are applied on the glaze, and not on the biscuit.

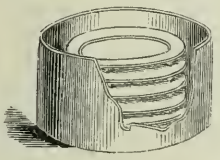

Fig. 13.

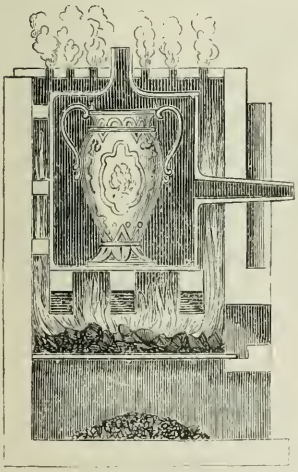

Fig. 14.

In the decoration of painted pottery and porcelain the colours employed are coloured glasses ground to impalpable powders, and mixed with borax or some other fluxing material. For use they are generally made liquid with oil of spike, and they are laid on with hair-pencils, in the same way as oil-colours. The whole process is exactly the same as in painting or staining glass; the glaze on the biscuit-porcelain being true glass, and the enamel colours being exactly the same as those used by the glass decorator. The colours may be made by mixing the materials of which glass is made with the colouring material and the flux, or simply with the already coloured glass and the flux. When the former plan is employed the principal colouring materials made use of are oxide of chromium for green; oxide of iron for red, brown, violet, gray, and yellow; oxide of uranium for orange, yellow, black; oxide of manganese for violet, brown, black, and purple; oxide of cobalt for blue, gray, and black; oxide of antimony for yellow; oxide of titanium for yellow; oxide of copper for green; suboxide of copper for red; sesquioxide of iridium for fine black; protochromate of iron for brown; chromate of lead for yellow; chromate of barytes for yellow; chloride of silver for deepening reds and purples; purple of Cassius for ruby and purple. Several of these colours are much increased in brilliancy by the addition of oxide of zinc, which of itself gives no colour; and the transparent ones are rendered opaque by the addition of oxide of tin.

Other fluxes besides borax are used—as sand, felspar, boracic acid, minium or litharge, salt, saltpetre, potash, and soda. For the gilding of pottery gold-leaf is rubbed down with oil of turpentine; or metallic gold is produced by precipitating the metal from its solution. The finely-divided gold so obtained is washed and dried, and then worked up with one-sixteenth of its weight of oxide of bismuth and oil of turpentine, painted on, fired, and afterwards burnished.

History.—The most ancient pottery of which we have any trace consists of the rude clay urns, vases, and other vessels found in the tombs of the prehistoric races. These remains exhibit the art of the potter in its most elementary condition, yet they are not devoid of elegance of form, and the decorative instinct of primitive man found appropriate expression on them in bands of incised lines forming lozenges, zigzags, and other geometrical forms, and in impressed wavy cord marks, &c. See Lake-dwellings, Stone Age, Troy.

Egyptian.—If we except the races of the far East, it is to the Egyptians among historical nations to whom precedence must be assigned in the art of the potter. We know that at a very remote period people made bricks of sun-dried clay cemented with straw, which were sufficient for the purposes of construction in a country where there is scarcely any rainfall. Vases of baked earthenware were also in use at the earliest period of Egyptian civilisation, and glazed tiles are preserved which belong to the epoch of Rameses III., not long after the exodus of the Israelites from Egypt. That the Egyptians attained considerable skill as potters is attested by the lustrous red ware they made for holding perfumes, wine, honey, and other delicacies; but their most remarkable pottery was their so-called porcelain made of a fine sand or frit covered with a thick siliceous glaze, blue, green, white, purple, or yellow in colour. The blue colour—which is that principally employed—was produced by an oxide of copper which yielded tints of unrivalled beauty and delicacy. This famous porcelain was made as early as the 18th dynasty (about 1600 B.C.), and continued to be produced till the period of the Greek and Roman rule. It was fashioned into vases, sepulchral figures of deities, scarabæi, beasts, &c.; and it must have attained a great reputation, for remains of it are found in most of the ancient countries which had commerce with Egypt. The unglazed Egyptian bottle (fig. 15) illustrates the fact, also attested by

early Greek vases, that the vase as well as the statuary figure had its origin in the human form. On these early vases the head, hands, and other members are figured, and the body of the vase is only an exaggerated human trunk.

Fig. 15.—Unglazed Egyptian Bottle in the British Museum.

Assyrian.—In the contemporary empires of Assyria and Babylon pottery was also in use at an early period. Sun-dried and kiln-dried bricks were made about 2000 B.C., and like Egyptian bricks these were stamped with the names and titles of the reigning monarchs, and the locality for which they were destined. Glazed bricks of various colours, occasionally enriched with figures of men and animals, were introduced into constructions, and Semiramis is said to have adorned with them the walls of Babylon. In these bricks we have the earliest example of the employment of materials for colouring like those now in use. The glaze, however, is siliceous. Glazed polychromatic bricks were also used in the construction of the walls of the palace of King Darius, the contemporary of the prophet Daniel, at Susa (scriptural Shushan). These bricks were moulded so as to build together into regular geometrical patterns, colossal figures of men, &c. in high relief. The objects most remarkable for size are the large coffins found at Warka, supposed by some to be the 'Ur of the Chaldees.' The Assyrians and Babylonians used terra-cotta for historical and legal purposes, making cylinders, hexagonal prisms, tiles and tablets of it, on which were impressed extensive writings in the cuneiform character. Some of the most remarkable of these tablets contain an account of the campaign of Sennacherib against Judæa and the tributes of Hezekiah; others give a record of the flood, the creation, &c. See BABYLONIA.

Phœnician.—Contemporaneously the Hebrews and Phœnicians practised the art, but of purely Hebrew work few traces remain. Phœnician pottery, however, has been abundantly excavated in Cyprus, and may be taken as a type of the works of both peoples. It is principally of a cream colour and of a brick red body, ornamented in horizontal bands, with lines in umber and red, concentric circles, and other geometrical forms being the most common decoration. They also moulded rude figures of deities and of domestic animals, the latter having apparently been used as toys by children.

Greek.—The most remarkable pottery of antiquity was the Greek, which seems in its earliest development to have had a certain affinity with Phœnician products. The Greeks claimed the invention of the potter's wheel, and the principal cities contested the honour of the art, which is mentioned in Homer and attributed to Corœbus of Athens, Hyperbius of Corinth, or Talos the nephew of Dædalus. The Greek vases which remain to this day, principally recovered from tombs in Greece and in the lands to which its commerce extended, show that within a few centuries the art rose from the rude condition like that shown in prehistoric pottery till it reached a perfection and variety of form and a grace and dignity of decoration not since attained by the efforts of any people. It was the triumph of pure art, for the material of which the body of Greek vases is fabricated is of the commonest type, and the colours the artists had at their disposal were few and simple. The archaic pottery of the Greeks down to about the 7th century B.C. was like the rude earthenware of prehistoric times. Their first improvement consisted in the application of a brown glaze to the surface of the ware, which enabled them to give force to the incised ornament, scratched through the glaze into the differently coloured body. Next the potters discovered black pigment which they could apply over the brown glaze, and thus increase their decorative resources by painting geometrical patterns in black. By degrees the purely geometrical forms of ornament were abandoned, and figures of animals, rising ultimately to the human figure, were painted in black silhouette on the vases, some of the details being touched with white and purple. In the case of the human figure faces and limbs began to be expressed in white and colour on the black figures painted on a red ground. Concurrently, the rough clay body of the vases began to be wholly or partially covered with an engobe or slip of clay of much finer quality and colour, the engobe being applied by dipping the moulded article into a vessel containing the slip. With these developments in material and decorative variety the forms of the vases and the skill of the artist draughtsman show steady and continuous development. Just as the best period in Greek art approached the favourite method of vase decoration underwent a total change. The decorative figures, deities and men, were traced on their red and white clay surfaces; but, instead of the figures being filled up in black, the surrounding space—the body of the vase itself—was blackened, giving a black varnished background with figures the colour of the underlying body. The details of these figures are indicated with fine lines. Sometimes the faces and limbs are filled up in white, and the draperies may be parti-coloured. At this stage Greek pottery reached its greatest loveliness of form and perfection of ornamentation, the drawing being supremely refined, delicate, and spirited. Among the most interesting of the Greek vases which remain to us are certain of the Panathenaic

Fig. 16.—Greek Krater, Amphora and Kylix of later style.

amphoræ—prizes won at the public games in Athens—on one side of which was painted an archaic figure of Athena, and on the other any appropriate design with the inscription: ΤΩΝ ΑΘΕΝΕΘΕΝ ΑΘΛΩΝ. In most cases also they contain the name of the archon or chief-magistrate of the city for the year, in this way enabling us to find the precise date of the manufacture. Of these vases ten are in the British Museum, six of which bear the name of the archon, and the Louvre possesses three, which, from the archonic names they bear, can be referred to 323, 321, 313 B.C.

respectively. At this period the decadence of Greek art had already set in. The drawing degenerated speedily, figures were multiplied and crowded in confusion, ornament became florid and superabundant, and the proportions of the vases became exaggerated and bad. Subjects themselves were no longer lofty and heroic, but connected with incidents of everyday life, with burlesque drama, and with jugglery.

In the history of Greek art no subject has excited more widespread interest within recent years than the terra-cotta figurines or statuette figures and groups found principally in tombs and about temples of the later period. From 1873 downward a great number of such figures were excavated from tombs at Tanagra in Bœotia; subsequently a very important find was made at Myrina on the coast of Asia Minor, opposite the island of Mitylene, and at Tarentum, Corinth, the Crimea, Cyprus, the Cyrenaica on the African coast, and in other localities quantities of such figurines have been obtained. The Tanagrine figurines were found in tombs which contained no painted vases; but some glass vessels, lamps, and inferior black pottery were associated with them, indicating that the statuettes belong probably to near the Christian era. The terra-cotta of the Asian coast comes down to a period as late as the time of Septimius Severus. The objects from the Tanagra tombs consist principally of single figures and groups of draped females and young girls; subjects drawn from the everyday life of the people, treated with true Attic grace and simplicity, and with marvellous sculpturesque feeling. In the Myrina series, which obviously have a different inspiration, deities and heroes of mythology form the most important element—Aphrodite and Bacchus, Silenus, satyrs, and mænads frequently recurring. The figurines are mostly polychromatic, sober, earthy colours, not fired in, having been used to tint them; but in some the colours are true enamel pigments. Miniature reproductions of known statuary figures and groups also occur among these exquisite works in terra-cotta.

Etruscan.—From the fact that much Greek pottery has been found in Etruscan tombs, this ware came to be popularly known as Etruscan pottery. True Etruscan pottery, however, was rarely painted. The most characteristic ware of that people, with a body black throughout, had on its surface moulded ornaments, the shape and ornamentation showing that it was modelled on oriental metal-work. This black Etruscan ware, which was in use from 500 to 320 B.C., was the source from which subsequently arose the Aretine and so-called Samian ware of Rome.

Roman.—The only important development made in pottery under Roman rule was this Aretine or

Fig. 17.—Samian Bowl.

Samian ware. It is evidently imitated in its decoration from works in metal, in all probability from the chased cups of silver and gold which began to come into use in Italy, and was a continuation of the later moulded wares of Greece and Italy. The Samian ware of the Romans, so called from having originated in the island of Samos, was of a bright red colour throughout, but covered with a lustrous siliceous glaze. The red colour nearly resembles in appearance and texture a coarse sealing-wax; the paste is often remarkably fine. The vases, generally of small dimension, were turned on the lathe; the ornaments were moulded separately, and attached to the vase; patterns were produced by the repetition of the same mould, or by placing the bas-reliefs from various moulds on the vases. This kind of pottery was first made by the Romans at Arezzo, but subsequently, or nearly simultaneously, was produced at Capua and Cumæ in the 1st century. It afterwards extended over all the Roman world, and was made in Gaul and Germany. While under the republic it was at first extremely fine, the manufacture deteriorated under the last of the twelve Cæsars, and the ware is no longer found under the Antonines. The names of several hundred potters are found stamped upon existing specimens of this ware, some of them evidently of Gaulish origin. It was extensively imported into Britain and other remote provinces of the empire. In Britain the Roman conquerors established the manufacture of pottery in many localities, making use of the native clays. The ware was generally of inferior quality, but that of some places is sufficiently distinctive; and the discovery of kilns and fragments enables us to associate certain localities with distinct classes of pottery. Thus, a black ware was made at Castor in Northamptonshire, which was ornamented with reliefs laid on by depositing a fluid clay on the wet body, and moulding it with a tool. Characteristic ware was also made under Roman influence at Upchurch in Kent, and near Crockhill in the New Forest, Hampshire.

Rhodian and Hispano-Moresque.—The knowledge of glazes originally acquired by the Egyptians and Assyrians was continued and transmitted to the Persians, Arabs, and Moors; and through oriental influence it came to be a European possession in mediæval times. Under the Knights of St John of Jerusalem, Persian potters were set to work in the island of Rhodes about the beginning of the 14th century. For about 100 years thereafter a large amount of a brilliant enamelled pottery was made, and sent out through the Mediterranean basin from that island. The pottery was distinctly Persian in form, colour, and ornamentation, and under the name of Rhodian ware existing specimens of it are greatly treasured. About the same time there was planted, under Moorish influence, on the Spanish peninsula and in the Balearic Isles the manufacture of the famous Hispano-Moresque enamelled faience, which is specially remarkable for the brilliant metallic lustre of its glaze. The industry continued to flourish till the final expulsion of the Moors from Spain early in the 17th century, after which it rapidly fell away. From the island of Minorca especially a vast trade in this ware was carried on; and the name 'Majolica,' given by the Italians to their own more famous enamelled pottery, is an indication of the predominant importance of the ware sent out from Majorca in the middle ages.

Fig. 18.
Hispano-Moresque Vase.

Italy.—There can be no doubt that the production of brilliant enamelled pottery simultaneously in the East and the West—in Persia, Damascus, and Rhodes on the one side, and in the Spanish peninsula on the other, exercised a powerful influence on the origin and progress of the same art in Italy. But there, under the contemporaneous renaissance of art generally, the decoration of the pottery assumed a distinctively European character, and it attained a much greater freedom, wealth, and variety of decorative resource than was reached by any of its predecessors. The use of the fine white enamel glaze yielded by tin is in Italy first associated with the name of Luca della Robbia (1400–81), the great sculptor, who employed it in coating his terra-cotta relief figures and groups, works which are now among the most prized treasures of art. From his time onwards the application of this tin enamel to earthenware became common in Italy, and it is to such pottery that the name Majolica properly belongs. One of the most famous of the many artists who produced this ware was Giorgio Andreoli, commonly known

Fig. 19.—Deep Dish, by Giorgio.

as Maestro Giorgio, who worked at Gubbio during the first half of the 16th century. His pieces, Gubbio ware, are distinguished by a remarkable iridescence, flashing ruby, golden, and opaline tints of marvellous brilliancy with every variation of light. Among the most famous centres of Majolica production in Italy besides Gubbio were Pesaro, Urbino, Castel Durante, Diruta, Faenza, Forli, and Venice. The artistic value of the products declined with the waning of art in Italy in the 17th century.

France.—From Italy the art of making enamelled faience passed with Catharine de' Medici into France, and the manufacture was established on Italian models in Nevers about 1590, and there it flourished till the end of the 17th century. But previous to that time the celebrated Bernard Palissy in 1555, after unheard-of exertions, had independently discovered an enamel glaze, which he applied to his characteristic rustic dishes, embellished with exquisitely moulded figures, in high relief, of fishes, reptiles, fruits, and other figures. But while Palissy was pursuing his investigations there was being produced in France a limited number of specimens of a ware which has become much more famous than the works of any other pottery, ancient or modern. During the last fifty years only attention has been prominently drawn to a few examples of pottery, very distinctive in form, exceedingly rich in decorative treatment, and highly original in the method by which it had been elaborated. At first it was known as Henri Deux ware, from many of the pieces containing the cypher and emblems of Henry II. and

Fig. 20.—Palissy Dish, La belle Jardinière.

of Diana of Poitiers. Subsequently, owing to the acceptance of a false theory of its origin, it was designated Oirin ware; but, after much investigation and many suggestions, it has been discovered that the pieces were made at St Porchaire (Deux-Sèvres) between 1525 and 1555. Henri Deux ware consists entirely of decorative pieces treated in an architectural manner, the body of the ware being a creamy pipeclay, with inlaid ornamentation in colour, and beautifully modelled masks, trusses, &c., and a transparent glaze. Only sixty-five pieces are known, and when any now change hands it is at an enormous price. In the Hamilton

Fig. 21.—Vase of Henry II. Ware.

sale (1882) a small cup 4 inches high brought £1218, and a salt-cellar 4 inches high was sold for £840. At the Fountaine sale (1884) a candlestick 12¾ inches high was disposed of for no less than £3675.

Holland and Germany.—The celebrated enamelled faience of Holland owes its origin to the attempts of the Dutch to imitate the oriental porcelain with which they were made familiar by their eastern trade and connections. The manufacture dates only from the 17th century, and from the fact that it was principally centred at Delft fine pottery came to be known generally in Britain as Delft

ware or 'Delft.' To imitate the fine lustrous white of the ordinary porcelain body tin-enamel glaze was employed by the Dutch potters, and their coloured decorations were in blue, and at first entirely oriental in character. Stoneware Bellarmines or Greybeards (q.v.), and the tall beer-jugs of the Germans, usually decorated with moulded ornaments, medallions and inscriptions, &c., although generally spoken of as Grès de Flandres, are really almost exclusively of German origin, and may be traced, according to their colour and quality, to the neighbourhood of Cologne, Coblenz, and to Kreussen in Bavaria, &c. Stoneware vessels of the same nature were also made in England early in the 18th century.

England.—Till the close of the 17th century the ware made in England was of a coarse, common description, and those who could afford the luxury obtained their pottery from the Dutch and other superior makers. The first step towards improvement was effected by John Dwight, M.A., who in 1671 obtained a patent for 'making stoneware, vulgarly called Cologne ware,' and by him the Fulham manufacture of stoneware was originated. A still more marked influence was produced on English pottery about the same time by the two brothers Elers, from Nuremberg, who settled at Burslem, and there produced a ware which they called red Japanese. To these potters we also owe the origin of the process of salt-glazing of stoneware. Finding their secrets were discovered by Astbury, they removed to Lambeth, where they established themselves in 1710. From this time onwards improvements were introduced in the Staffordshire potteries; but the great strides which for a time put English pottery in the foremost rank of the productions of the world were due to the great potter Josiah Wedgwood (1730–95, q.v.). In every department, in body or paste, in methods of decoration, and in the employment of artists of the highest ability, Wedgwood, with untiring application and with unstinted expenditure, aimed after perfection; and his efforts alone raised the manufacture of pottery in England to the position of an industry of national importance. Away from Staffordshire potteries of some importance existed at Lambeth, Bristol, Liverpool, Leeds, Lowestoft, and Swansea; but by degrees the manufacture drew more and more towards Staffordshire, where, in the towns collectively known as 'The Potteries,' embracing Stoke-on-Trent, Etruria, Hanley, Burslem, and some others, it now principally centres. Josiah Spode (1754–1827) made a famous kind of opaque porcelain or 'ironstone china.' English stoneware and pottery owe much to Sir Henry Doulton (q.v.) and his works at Lambeth, in the Potteries, and near Glasgow.

Fig. 22.—Early Staffordshire Tyg or four-handled drinking cup.

Peruvian.—In the New World the art of the potter showed an interesting development among the ancient Mexicans and Peruvians before the American continent became known to Europeans. No knowledge of glazes existed among these peoples, but, in the case of the Peruvians especially, a high degree of skill in working clay was developed; and they modelled and modified animal forms with great knowledge and spirit. Their most characteristic pottery was black, but they also made vessels of a fine, warm, yellowish body, formed on the potter's wheel, and having painted decorations analogous in style to those on archaic Greek vases.

PORCELAIN.—The substances with which we have dealt in this brief historical summary up to this point comprise only pottery, as contradistinguished from porcelain. The term porcelain is of Italian origin, derived from *porcellana*, the cowrie shell, owing to the similarity of the white glazed surface of the ware to the substance of that shell. Of porcelain there are two varieties, one being soft or artificial porcelain, the *pâte tendre* of the French, which may be looked on as a chemical compound, and which is wholly fusible at high temperature. The second variety, hard or kaolinic porcelain (the French *pâte dure*), is the true oriental porcelain, composed of two natural mineral substances alone, Kaolin (q.v.), an infusible white clay, and pe-tun-tse, a mixture of felspar and quartz, fusible in its nature, the presence of which gives its semi-fused translucent appearance to the ware.

China.—It is to the Chinese that the world owes the manufacture of porcelain; and in strict chronological sequence, in antiquity of the industry, in skill and resource in working raw materials, and in richness and variety of the finished products the Chinese ought to have the first place. When the Greeks were making their terra-cotta vases the Chinese were manufacturing porcelain; they had mastered the secrets of that most difficult of all ceramic tasks 2000 years before it was accomplished by Europeans. According to their own records, pottery was made in the Chinese empire in the reign of their mythical Emperor Hwang-ti about 2690 B.C. Without assuming the historical accuracy of such a precise date, there is no doubt that true porcelain was made in China under the Han dynasty between 206 and 87 B.C. From that time onward the art developed and improved, and, subject to fluctuations caused by revolutionary troubles, the porcelain manufacture continued to flourish in China till recent times. The most famous centre of the industry was formerly King-te-chin in the province of Kiang-si, where it is known porcelain was made about 580 A.D. In this town alone there were early in the 18th century no fewer than 3000 porcelain furnaces; but the place was ruined by the Tai-ping insurrection. Chinese porcelain exhibits endless variety in form and painted decoration. The mythical dragon, the kylin or mythical lion, the spotted deer, domestic fowls and other birds are favourite subjects on Chinese ware. Of all Chinese porcelain that now most sought after is the old blue ware such as was at first copied and imitated by the Delft manufacturers. Crackle ware, in which the glaze shows signs of separation from the body, is a peculiarity of oriental manufacture. The Chinese appear to possess the secret of causing the cracks in the glaze to be large or minute at will. Ruby glazed ware (the *Sang de bœuf* of the French) and rich chromatic splashed glazes are also highly treasured in Chinese porcelain. The soft sea-green glazed ware known as Celadon glaze

Fig. 23.—Chinese Porcelain Vase.

is assumed to be the earliest form of Chinese porcelain, and genuine ancient pieces are highly valued.

Japan.—A knowledge of Chinese porcelain passed into Japan as early, it is said, as 27 B.C.; and it is known that a corporation of porcelain-makers was established in that country in 720 A.D. In the 13th century a Japanese potter went to China to improve himself in the art of porcelain-making, and after his return he carried on the manufacture in his native country with great success. It is, however, more in the manufacture of pottery than of porcelain that the Japanese exhibit pre-eminent skill. Their most famous manufacture consists of Satsuma ware, so called from having been established in the neighbourhood of Kyōto by the formerly powerful princes of Satsuma. It is of a pale yellowish colour, covered with minute crackles in the glaze, and very richly painted and lavishly gilt. The so-called Satsuma now manufactured is yellower in colour than genuine old pieces, and it is principally made at Awata near Kyōto. The Japanese potters generally display a remarkable power in moulding pottery and finishing its surface so as to imitate other substances, such as woods of various kinds, basket-work, &c. Among their most remarkable products as examples of delicate moulding is Banko ware, which consists of small teapots and other vessels of a brownish and grayish unglazed earthenware, extremely light and thin in body, and very much appreciated among the native population for tea-making. The Japanese excel in the manufacture of egg-shell porcelain, so called on account of the extreme thinness of the body. Among their other porcelain manufactures Kaga ware is the most outstanding, being characterised by painted ornaments in a rich ruby colour, which is generally lavishly gilt. The chrysanthemum is a favourite and frequent flower in their vases, the crane and other birds figure most effectively, and figures of warriors and ladies are frequently employed in the resourceful and varied ornamentation of Japanese ware. The principal centres of the pottery industry in Japan are in the province of Hizen, where at Arita is produced Imari ware; the province of Owari, whence comes Seto ware; Kaga, for ware of that name; and Mino and Kyōto.

Persia.—Chinese porcelain was known in Persia as early as the 12th century, a circumstance not to be wondered at, seeing that country was then and for centuries before the principal highway of commerce between the far East and Europe. Many evidences exist of the acquaintance of the Persians with the ceramic products of China; and at an early date pottery and a species of soft porcelain were made in Persia which both in form and decoration were modelled on Chinese originals. But Persia also had a manufacture of pottery and of enamelled tiles of an original and distinctive character, in which on a fine white enamelled glaze brilliant metallic lustres were employed in a most effective and original manner.

Porcelain in Europe.—In the 13th century the early European traveller, Marco Polo, visited the porcelain-factories of China. In 1487 Lorenzo de' Medici received from the sultan of Egypt a present of Chinese porcelain, and that is the first record we possess of the appearance of the ware in Europe. The Portuguese were the first to import porcelain direct from the East; and subsequently large quantities were brought by the Dutch and by the East India Companies of other nations. No sooner did the ware become known in Europe than strenuous efforts were put forth in many quarters to imitate it. A certain amount of porcelain is alleged to have been made in Venice about 1470; but the earliest European porcelain of which any examples exist is that which was made by Francis de' Medici II., Grand-duke of Tuscany, about 1580. The quantity made appears to have been small, and the attempts at the manufacture ceased with the death of the grand-duke in 1587. Nearly a century later the art was revived at Rouen and at Paris, but it was not till 1693 that a permanent and well-established industry was founded in France at St Cloud. Thereafter it was taken up in other French towns. At Vincennes it was begun in 1745; in 1753 Louis XV. became a partner in that concern. In 1756 the works were transferred to Sèvres, and in 1760 that establishment became entirely national property; and so it has continued amid all fluctuations of government to the present day. Hard porcelain was first made at Sèvres in 1764; but the fame of that establishment rests on its soft porcelain, in which body, glaze, and enamel colours blend together into a singularly smooth and lustrous whole.

But in Europe it was in Germany that the secret of making hard or kaolinic porcelain was first discovered. After years of labour and innumerable trials, which resulted only in the production of a kind of opaque glass or stoneware, Böttger (q.v.), an alchemist who had entered the service of Frederic Augustus II. of Saxony, succeeded in 1709 in making a white hard porcelain at Meissen, near Dresden. The china-clay and china-stone he employed had previously been discovered by Schnorr at Aue. Extraordinary precautions were taken to prevent the process of the manufacture from being revealed; but, notwithstanding the oaths imposed on the workmen and the other means employed for their supervision, the secret was betrayed by one Stölzel, who fled to Vienna, and there the imperial factory which continues to this day was established in 1718. Subsequently factories under national protection were established at Höchst in 1740, at St Petersburg in 1744, at Berlin in 1750, and at Ludwigsburg in 1758. Works at which soft porcelain was principally made were established at Doccia near Florence in 1735, at Capo di Monte near Naples in 1736, and at Buen Retiro in Spain in 1759; and the products of all these manufactories have attained considerable reputation.

Fig. 24.
Dresden Candelabrum.

In Great Britain manufacturers have at all times devoted themselves principally to the making of a variety of soft porcelain. The works at Chelsea, Bow, and Derby were established about 1745, and in 1751 the manufacture began at Worcester, where it still continues. Hard porcelain-making was begun by Cookworthy at Plymouth in 1768, after he had discovered china-clay in Cornwall. But his works continued only for about three years. Cookworthy's patent rights were then transferred to Richard Champion, who continued the manufacture at Bristol till 1781. In Staffordshire porcelain was first made at Longton Hall near Newcastle in 1752, but it was not till about the close of the 18th century that Staffordshire porcelain became artistically and technically fine in the hands of Thomas Minton, who founded the famous works of Minton & Company, and of Josiah Spode, whose undertaking continues under the firm of Copeland & Company.

In the later part of the 18th century valuable porcelain was also made at Lowestoft, Coalport, Nantgarw, Swansea, and some other centres. The manufacture of Parian or statuary porcelain, which is an unglazed modification of English soft porcelain, was introduced by Copeland and Minton about 1848.

It is a common practice to place on pottery and porcelain distinctive marks, either painted on or stamped into the bottom of the article. These indicate either the manufactory in which the pieces were made, or the workman, and sometimes the decorator, employed on them; and in the case of Chinese and Japanese ware the marks give the dynasty or date of execution. It is only in the case of Sèvres porcelain that the habit of marking a date by letters of the alphabet was practised. In Chinese porcelain date-marks are found indicating that the piece was made as far back as the 10th century; but there is reason to believe that many of these early marks are forged, and at most are only copies of more ancient examples which have now ceased to exist. On some pieces of early majolica the date, place, and name of the artist are given. The great European manufactories have generally marks which indicate the place of making only; but there are other means of arriving approximately at the date. The illustrations (fig. 25) show the marks employed at various important English works; but many of the manufacturers imprinted or impressed their names in full. In connection with these marks and names it should be borne in mind that it is easier to forge marks and names than it is to produce works equal to the originals

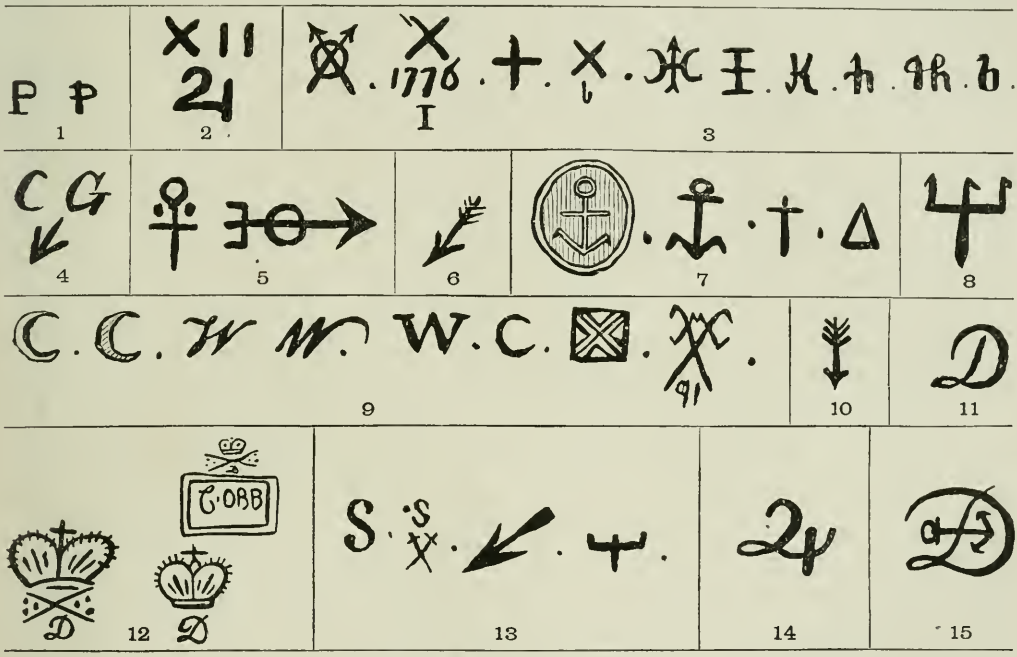

Fig. 25.—Marks on English Ware:

(1) Pennington, Liverpool, 1760–80; (2) Plymouth, about 1760; (3) Richard Champion, Bristol, 1772–90; (4) Charles Green, Leeds, 1790; (5) Bow, 1730–90; (6) Absolon, Yarmouth, about 1790; (7) Chelsea, 1730–84; (8) Swansea, Wales, 1790; (9) Worcester, 1760–80; (10) Yarmouth, about 1790; (11) Derby, 1751–69; (12) Crown, Derby, 1780–1830; (13) Shropshire, 1772–90; (14) Cookworthy, Plymouth, 1760; (15) Derby-Chelsea, 1770.

imitated, the excellence and value of which causes such forgeries to be put in circulation. There is a vast quantity of forged porcelain in existence, and, specially, imitations of the fine old soft porcelain of Sèvres and of other famous *fabriques* are very abundant.

The literature of pottery and porcelain is exceedingly voluminous. Among standard works of general interest may be mentioned Brongniart, *Traité des Arts Céramiques* (3d ed. 1877); Marryat, *History of Pottery and Porcelain* (2d ed. 1864); Jacquemart, *Histoire de la Céramique* (1873; Eng. trans. by Mrs Palliser, Lond. 1873); Garnier, *Histoire de la Céramique* (Tours, 1882); Davillier, *Les Origines de la Porcelaine en Europe* (1883); South Kensington Museum *Art Handbooks;* Birch, *Ancient Pottery* (new ed. 1873); Rayet and Collignon, *Histoire de la Céramique Grecque* (1888); Jewitt, *Ceramic Art of Great Britain* (new ed. 1883); Solon, *The Art of the Old English Potter* (2d ed. 1885); Meteyard, *Wedgwood and his Works* (1873); Audsley and Bowes, *Keramic Art of Japan* (1881); Garnier, *La Porcelaine Tendre de Sèvres* (1889 *et seq.;* English trans. nearly simultaneously); Bowes, *Japanese Pottery* (1890); Darcel and Delange, *Recueil de Faïences Italiennes* (1867). For marks and monograms: Chaffers, *Marks and Monograms on Pottery and Porcelain* (7th ed. 1886), his smaller *Collector's Handbook* (new ed. 1890); Palliser, *The China Collector's Pocket Companion* (1874); Graesse, *Guide de l'Amateur de Porcelaine et des Poterics* (4th ed. Dresden, 1873).

Potton, a market-town of Bedfordshire, 11 miles E. of Bedford. Pop. 2006.

Pottstown, a borough of Pennsylvania, on the Schuylkill River, at the mouth of Manatawny Creek (both crossed by bridges), 40 miles by rail NW. of Philadelphia. It contains iron-foundries, blast-furnaces, rolling-mills, nail-factories, car-works, &c. Pop. (1880) 5305; (1890) 13,285.

Pottsville, capital of Schuylkill county, Pennsylvania, is built on the side of steep hills, on the Schuylkill River, at the entrance of Norwegian Creek, 93 miles by rail NW. of Philadelphia. It is in the midst of a rich anthracite coal and iron region, and has several iron-furnaces, foundries, rolling-mills, machine-shops, sawmills, &c. Pop. (1880) 13,253; (1890) 14,117.

Pot-wallopers (from *pot*, and *wallop*, 'to boil or bubble'), the popular designation of a class

of electors forming the constituency of various English boroughs (e.g. Taunton, Preston) before the Reform Act of 1832, and defined in Sir James Stephen's *Commentaries* as 'such as cook their own diet in a fireplace of their own.' At Taunton in the 18th century 'several inmates or lodgers would, some little time before the election, bring out their pots, and make fires in the street, and boil their victuals in the sight of their neighbours, that their votes be not called in question' (Defoe's *Tour through Great Britain*, 4th ed. 1748).

Pouched Mouse (*Dipodomys*), a genus of small, lean, long-tailed, agile rodents, with cheek-pouches. The best-known species is *D. philippii*, from the waste regions of California, where it seems to find a sparse diet of seeds and roots, and in the dry season no drink but dew.

Pouched Rat (*Pseudostoma* or *Geomys*), a genus of plump, short-tailed, hamster-like rodents, with cheek-pouches which open externally and are used as receptacles for food. One of the best-known species is *P.* or *G. bursarius*, sometimes called 'Gopher.' Like the other species it is a native of North America, and inhabits the territory east of the Rocky Mountains and west of the Mississippi. It is a burrower like the mole, active in the warm weather, hybernating in the cold, sluggish above ground, but very active in its subterranean progress. The cheek-pouches are very large, and are crammed with roots, seeds, &c., but not with earth as the Indians used to maintain. Being voracious gnawers, the pouched rats do much damage to the roots of trees and crops.

Poughkeepsie, capital of Dutchess county, New York, on the east bank of the Hudson River, 73 miles by rail N. of New York City, is finely situated on a tableland, about 200 feet above the river. The Hudson is here crossed by a steam-ferry, and spanned by an important railroad bridge of masonry, steel, and iron (finished in 1888); the structure rests on six piers—four in the channel—and is 3094 feet in length from anchorage to anchorage, or, including the approaching viaducts, nearly 7100 feet. Over three spans are cantilevers, with arms of 160 feet. The city is well built, with fine public and private edifices; Main Street runs back 2 miles from the river. Poughkeepsie is the largest town between New York and Albany; its manufactures include machinery, iron-ware, silk, boots and shoes, clothing, &c., and it has a rolling-mill, a blast-furnace, and several breweries. Two miles to the north is the Hudson River State Hospital for the Insane, which cost $750,000, and the city contains a number of charitable institutions. But Poughkeepsie has most reason to be proud of its educational facilities. Vassar College (q.v.) is just beyond the eastern city limit, and the town possesses also a collegiate institute, a business college, and several high-class seminaries and academies, besides the public schools. Poughkeepsie was settled by the Dutch about 1680; in 1778 it was the state capital, and in 1788 the New York Convention met here to ratify the constitution of the United States. Pop. (1870) 20,080; (1890) 22,206.

Poulpe. See Octopus.

Poultice, an application to diseased or painful parts, for the purpose of promoting suppuration, relieving pain, and stimulating or soothing the skin, according to circumstances. A poultice may be composed of any moist pulpy substance of sufficient consistence to retain the water without dripping or soaking through the flannel or linen covering in which it is generally applied. The making of a poultice well is a matter of some nicety, and unless the proper consistence is given to the mass the application is apt to do more harm than good. The linseed-meal poultice is the most easily made, and most satisfactory of all soothing applications. The meal is stirred gradually into a sufficient quantity of boiling water, placed in the bottom of a small basin or teacup, until a perfectly smooth pulp is formed of the proper consistence, and in quantity sufficient to cover completely, to the thickness of three-quarters of an inch, the whole pained part. The pulp is then spread on flannel, or poured into a flannel bag, and applied as soon as the heat will permit it to be borne. If it is to be applied to a wound, threatening abscess, &c., where a softening effect on the superficial tissues is desired, some oil should be smeared over the surface, and the poultice put directly in contact with the skin. If applied for pain, or some deeper inflammation where heat is chiefly needed, the oil is unnecessary, and the poultice should be enveloped in cotton-wool or in several layers of flannel. It can then be borne hotter, and will retain its heat longer. The bread and milk, or even bread and water or bran poultice, is also very good; as is also the oatmeal-porridge poultice, to which a little butter may be added with advantage. A spoonful or two of yeast may be added, if there are foul discharges, or charcoal may be used alone, or sprinkled on the surface of the poultice before it is applied, or it may be made with a non-irritating antiseptic lotion instead of plain water (e.g. corrosive sublimate, 1 to 2000). Carrot poultices are in great favour with the people in some parts of the country. Hemlock poultices, made of the fresh leaves, or of the dried leaves, with the aid of some powder of the leaves, form a valuable sedative application in painful diseases; and poppy-heads, or even opium, are sometimes infused in the water of which a poultice is made, for the same purpose. A stimulating poultice may be made by sprinkling oil of turpentine, or chloroform, or mustard in moderate quantity on the surface of any ordinary poultice. When considerable irritation of the skin in a short time is desirable, a mustard poultice is used. For the danger of poulticing the eye, see Eye, Vol. IV. p. 513.

Poultry (Fr. *poule*, 'a hen;' Lat. *pullus*, 'a chicken;' Eng. *pullet*) is the term by which are known the birds brought by man into domestication, and usually embraces the ordinary fowl, ducks, geese, turkeys, and guinea-fowl. From the time when man began to abandon his nomadic manner of life and settle down into settled habitations, poultry in one form or another have been brought into subjection, taking the place of the wild birds which, when he wandered, he was able to snare or kill, but which fled from him when he chose one abode. Only in Asia is the ordinary fowl found in a wild state, chiefly in India. Here is yet to be found the *Gallus ferrugineus*, or *G. bankiva*, which, from its resemblance in every way to the modern fowl and the freedom with which the two breed together, is accepted as the progenitor of nearly all our domesticated varieties. At one time it was thought to be the parent of all, and this was the view of Darwin; but later researches have led to a modification of this opinion; there is no wild breed of fowl to which the Brahma and Cochin type of fowl can be traced. The Jungle-fowl of India, or *G. bankiva*, has plumage and colour not very dissimilar to the game fowl, and this type prevails largely in the great dependency. From the time of the ancients poultry have been bred and kept. Many records found in the writings of early days refer to the fighting qualities of the cock, and in some countries he was bred largely, if not chiefly, for this propensity. Theognis, Aristophanes, Aristotle, Diodorus, Æschylus, Plutarch, Plato, and Pliny all make reference in their writings to the fowl, which seems to have gradually spread over

Europe, being, it is supposed, brought into Britain by the Romans, since whose time it has been an important member of our domesticated animals. The fighting qualities of game fowls have always been specially studied, and Cock-fighting (q.v.) was once a recognised sport in the United Kingdom, followed by all classes of society.

Poultry are valued for two purposes: (1) for their flesh, and (2) for the eggs produced by them. In those varieties which are specially bred for the table the flesh is abundant, fine in texture, excellent in flavour, and easily digested. It enters very largely into the food-supply of the country in an ever-increasing ratio, and is strongly recommended to invalids or persons of weak digestion. Eggs (q.v.) are consumed to an even greater extent, and more generally than can ever be the case with poultry; for they are within the reach of all persons, and are used for every form of cooking, as also largely for manufacturing purposes. The great and ever-increasing demand in Britain for this class of food is seen in the vast imports, which have grown so enormously. In 1864 the value of eggs imported from the continent of Europe was £835,028; in 1870, £1,102,080; 1875, £2,559,860; 1880, £2,235,451; 1890, £3,428,802; and 1897, £4,356,807, besides poultry to the value of about half a million. And in the same period it is estimated that the eggs and poultry received into Great Britain from Ireland, which has always been a large poultry and egg producing country, amounted to one and three-quarter million pounds sterling, so that Britain's poultry and egg consumption, if we take the value of home production as equal to that of Ireland, is nearly seven and a half million pounds annually. A calculation was made in 1890, for the French minister of Agriculture, that the income derived from the sale of eggs and poultry in that country is £13,496,000—viz. £6,140,000 for poultry, and £7,356,000 for eggs. The number of fowls is computed at 45,000,000, representing a value of £4,500,000. It has been said that the daily consumption of eggs in the United States is 44,000,000, which would represent an annual value of more than $200,000,000.

Although the breeds of poultry are not so numerous as are those of pigeons, the development of breeds since the era of poultry-shows has been very great, and we have now some forty distinct varieties, several of which are again subdivided by different colours. There are about twenty varieties of ducks, seven of geese, and six of Turkeys (q.v.) domesticated. Ducks are most prolific layers, and there is always a good demand for their eggs, especially by cooks and confectioners. The breeds of ducks valued for table purposes and for breeding are almost all good layers—the Aylesbury, Pekin, and Cayuga breeds being famous; the eggs of the Rouen breed are rather smaller than those of Aylesburys. Fowls may be divided into four classes—viz. table breeds; laying or non-sitting breeds; general purpose breeds; and fancy or ornamental breeds.

Table Poultry.—Characterised by rapid growth, fine quality of flesh, and great breast development. *Dorkings.*—Old English breed, square bodied, white legs and feet, and five toes; four colours. *French.*—Seven varieties, all marked by large size, rich flesh, chiefly dark-legged. *Game.*—Have great breast muscles and fine flesh; not so large as the breeds already named; nearly half a score colours of game fowl may be found. *Indian Game.*—A very large breed, bred chiefly in Cornwall; beautiful in flesh quality, but darker than dorkings or French, and heavier in bone; can be fed up to a great size. In addition to these may be named Aseels and Malays, which are good as table fowls.

Laying or Non-sitting Poultry.—In these the laying powers have been greatly developed (some varieties producing upwards of 200 eggs per annum), and the maternal instinct has been suspended by disuse. They are chiefly of the Mediterranean family, but not exclusively so. These Mediterranean varieties have large single combs, a lightish body, and include Anconas (speckled), Andalusian (blue), Leghorns or Italians (of which are ten colours), Minorcas (black), and Spanish (black with long white faces). *Hamburghs.*—Under this term are two families, the Yorkshire and Lancashire Pheasant Fowls (spangled and black), as also the Redcaps, and the Dutch (pencilled), all very beautiful, and the most prolific layers we have. *Houdans.*—Another French breed, with a crest, pale legs, and five toes. *Polish or Polled.*—Have a very large crest, are good layers, but are delicate; of these there are six colours. *Scotch Greys.*—A cuckoo-plumaged fowl, with pale legs, good flesh, and suitable for cold climates.

General Purpose Poultry.—Breeds which are not specially good in any one quality, but well balanced and good all round; chiefly of the Chinese type—i.e. heavy in leg and bone, large in size, and with high tails. *Brahmas*—A Chinese fowl modified in Europe and America; two colours. *Cochins.*—The breed which made such a furore in the 'Fifties;' very handsome, but poor as a layer and moderate in flesh; five colours. *Langshans.*—Like the Cochin, of Chinese origin; an excellent layer of eggs with buff-tinted shells, and a capital table fowl; one variety, black in plumage. *Plymouth Rocks.*—A variety of American making, cuckoo in plumage, and excellent in economic qualities. *Wyandottes.*—Also of American origin; equal as a layer and for the table; four colours. All these make excellent mothers, as do most of those in the table-poultry section, and are very hardy.

Fancy or Ornamental Poultry.—These include the breeds which are either bred alone for their beauty or peculiarity of plumage, or by reason of diminutive size are of no service for economic purposes. They embrace the Game Bantams (six varieties), Bantams (thirteen varieties, but constantly being added to, many from China and Japan), Japanese Long-tailed, Silkies, Sultans, Frizzled, Naked Necks, Rumpless, &c.

That poultry can be made profitable is undoubted, but hitherto all attempts to establish poultry-farms as such have ended in failure. Considerable profit is often made by those who breed and exhibit pure-bred poultry, whilst the advantage of having fresh eggs and home-fed poultry is sufficient inducement to many who have the opportunities of keeping a few fowls, apart from the pleasure derived from them. Poultry can be kept under many conditions, and have been found to thrive in the most unlikely places, but all their wants must be artificially supplied. To maintain them in health they should have a house dry above and below, with 16 square feet of floor space for every half-dozen fowls of the medium-sized varieties, an outside shelter in which is placed a dust bath, this being the way in which their skin and feathers are cleansed, and an open run without. If they can be given full liberty it is all the better, for which reason movable houses placed out in fields or parks are the best; but often it is impossible to do this, and then not less than 6 square feet of ground should be allowed to each fowl if the run is laid in gravel or sand, or 100 square feet per bird if in grass, or it will all be eaten off and the ground left bare. Absolute cleanliness is essential for them in houses, nests, and runs, and the ground should be changed every two or three years, or it is liable to become foul from the richness of their manure. Fowls naturally eat grain, slugs, worms, &c., and, if the latter are not obtainable in the ground by them, some substitute must

be provided. For laying birds it is found that soft food is very beneficial, and it should be given in the morning, with hard corn in the later part of the day. Sitting hens should be provided for apart from other stock, as they require to be in a quiet place. The time of incubation is twenty-one days. When the brood has made its appearance the hen and chickens should be placed out in a coop, and the latter fed every two hours for the first fortnight, every three hours for the next two weeks, and after that four times a day until they reach maturity. Artificial incubation and brooding are very largely adopted by poultry-breeders, and have been brought to a remarkable state of perfection, the machines now sold working with great regularity and precision (see INCUBATION). The advantage of incubators is that they can be used at any period of the year, and are not dependent upon the weather, as is the case with hens. The Hearson and Westmeria incubators are the best, and the Westmeria brooder has proved remarkably successful for all kinds of poultry. This plan of working is largely employed in France and America. Poultry are polygamous, and from four to ten hens should be placed with each cock bird, according to breed and the season of the year.

Poultry-farming.—Many attempts have been made to establish poultry-farms, but they have always ended in failure, and it has come to be regarded as an axiom that poultry will not pay. The reasons for this failure have been twofold: first, that the amount of space necessary to keep the fowls in health when in large numbers, and the consequent increase in labour, were too heavy charges against the enterprise; and second, the placing of a large number of birds together, under conditions which were unhealthy, induced disease, and so ruined the scheme. The great mistake has been made in attempting poultry-farming as a separate industry, rather than as part of a larger enterprise. Where it can be grafted upon other work, an addition to the business of farming or fruit-growing, it can be, and has been, made successful in several notable instances. In these there is no separate charge for land; the labour is not on account of it alone; a large portion of the food needed by the fowls is obtained by themselves from the ground, and such as is given is at the first cost; the produce can generally be sold with what other is going to market, and especially if dairying or fruit-growing be also entered into, those who purchase milk or butter or fruit being generally willing to buy the eggs and chickens; and, finally, the land is enriched by the manure of the fowls, whilst its employment for other purposes will prevent its becoming foul, the great danger when only poultry are kept on the land, for disease is speedily induced by foul ground. The force of events during recent years has compelled many British farmers to take up what were at one time regarded as minor pursuits, and branches of farming which in themselves are not sufficient to give a living—for which reason they were neglected for larger things—have received attention. Or, as it has been expressed, 'commercial poultry will only pay as an accessory to something else, whether it be a farm or a household—to eat scraps which would otherwise be wasted . . . and to give to the land, in the shape of manure, properties which cannot otherwise be obtained except by a heavy outlay.' When we look to France, where poultry are bred to such an enormous extent, we find that poultry-farms as such have no existence, but that fowls are kept by every farmer and cottager. The same remarks apply to Italy, Denmark, and Ireland, from all of which countries England receives large supplies of eggs and poultry. In the wine districts of France fowls are permitted to wander amongst the vines all the year round, except just when the fruit is forming, and they do a most serviceable work in cleaning and manuring the ground. The poultry houses are placed in the vineyards, and in many cases are made sufficiently narrow to pass between the rows of plants.

In France, in the Surrey and Sussex districts of England, and also at Aylesbury, where so many ducks are fattened every year, systems of fattening are extensively carried on, but as a rule, in France especially, those who rear the birds do not fatten. Fattening is a business by itself, birds being purchased from the breeders when about eight weeks old. They are put into pens and fattened for a period varying from three to ten weeks, either by hand or with machines. Some of the latter are very elaborate, but as a rule they are simple. The head of the fowl is held in the left hand, and a brass nozzle, attached to a piece of india-rubber tubing, and connected with a cylinder, is inserted into the mouth of the bird. In this cylinder is a supply of liquid food, made of buckwheat or some other meal, milk, and a little fat, and it is so arranged that when a pedal is pressed by the foot a portion of the food, varying according to the stage of fattening—for it is increased in quantity each day until the process is completed—is injected through the tube and nozzle into the bird's crop. By this means the fattening is carefully and skilfully conducted, and there can be no doubt of the result, as every one who has tasted a well-fattened French fowl will be able to testify. In the La Bresse, Le Mans, and La Sarthe districts of France the number of fowls fattened every year is enormous, and the best specimens realise very high prices. The flesh is beautifully tender and white, and much more abundant than would be possible on an unfattened fowl. In Surrey and Sussex the method adopted is somewhat different, in that the birds are either fed by hand or with heavy crank cramming-machines, powerful enough to force semi-liquid food into the crop of the fowl. Here the process does not last more than three weeks. When the birds are killed they are immediately plucked, and placed, before they become quite cold, on shaping boards, so made as to give them the best appearance. In Ireland there is very little fattening carried on, and consequently the poultry from that country are poor and sell at about the lowest price on the English market.

Where poultry are kept in large numbers the best method of housing is by means of movable or portable dwellings, for these can be transferred about from place to place, giving the fowls fresh ground and distributing their manure, which is very valuable indeed, over the land. Under no circumstances should more than fifty be kept in one flock; and it will be found in practice that they will not wander far from their home, or mix with each other, even if the houses be placed in adjoining fields. The ordinary methods of management are applicable here. There can be no question that the increase in the size of farms, which has taken place within the last half of the 19th century, has done much to discourage poultry-keeping, and the opposite tendency ought to have a reactive effect (see PEASANT PROPRIETORS). Much might be done in the way of encouraging poultry-keeping by cottagers, who could maintain them with the minimum of cost and the maximum of results. A very important factor in successful poultry-keeping is the selection of right breeds, and it is essential that the produce should be marketed as speedily as possible. An egg two days old is worth twice as much as when two weeks laid, a fact which should always be borne in mind, but is too often forgotten. In the great cities and densely populated districts there is a constant demand for fresh eggs, and at

high prices. To secure the best returns all eggs and poultry should be sent to market clean, well packed, and in the best possible condition. The supply of the commoner varieties of poultry produce is very large, and the prices obtained are consequently small, but there is no limit to the demand for high-class qualities at remunerative figures.

See L. Wright, *The Illustrated Book of Poultry* (new ed. 1885); Tegetmeier, *Poultry Book* (new ed. 1872), and *Poultry for the Table and Market* (1892); *Poultry* (Dean and Son); S. Beale, *Profitable Poultry-keeping* (1883); I. K. Felch, *Poultry Culture* (Chicago, 1886); *Poultry-keeping for Farmers and Cottagers*, by the present writer (1893); also the articles Duck, Goose, Guinea Fowl, Turkey, Egg, Food, Incubation, &c.

Pounce, powdered rosin, or some gum-resin such as mastic, sandarach, or copal, and also the powder of cuttle-fish bones, formerly used for sprinkling over freshly-written writing to prevent blotting; fine sand was often substituted for pounce.

Pound (Sax. *pund*, Ger. *pfund*, Lat. *pondus*, 'weight'), long the unit of weight in the western and central states of Europe, differing, however, in value in all of them. The symbol 'lb.' for it is equally general, and is derived from the Latin word *libra*. The old English pound, which is said to have been the standard of weight from the time of William the Conqueror till that of Henry VII., was derived from the weight of 7680 grains of wheat, all taken from the middle of the ear, and well dried. For the difference between the present avoirdupois and troy pound, see Avoirdupois, Weights and Measures. In the British Pharmacopœia of 1864 the troy ounce was given up, and the pound avoirdupois and the ounce avoirdupois were adopted. See also Livre, Mark.

The pound weight of silver, a common money standard among the ancient Romans, was introduced by them into the countries they conquered, and thus the term 'pound' became a designation of a certain amount of coined money. Thus, nowadays, the English pound is considered as something (a coin or otherwise) equivalent to 20 shillings, but originally it denoted the pound of silver which was coined into 20 shillings. From Edward II.'s time the coins were more and more diminished in size, that monarch coining 25 shillings from a pound of silver; while from the same weight of bullion his various successors coined 30, 45, 48, 96, 144, 288, in the time of Elizabeth 60, and under George I. 66 shillings to the pound of silver, and this rate still continues, the term 'pound' being severed from its original meaning, and signifying 20 shillings of the present coinage. The sovereign of gold was first struck under Henry VII.; its value rose to as much as 30 shillings; under Charles II. it was fixed at 21 shillings, and the sovereign was superseded by the Guinea (q.v.) till 1817 (see Money, Mint). The pound Scots, originally of the same value as the English one, sank in value after 1355 till in 1600 it was but one-twelfth of the value of the English pound, and was accordingly worth 1s. 8d.; it was divided into twenty shillings, each worth an English penny. The Treaty of Union provided that the money thereafter used should be of the same standard and fineness throughout the United Kingdom.

Pound, in English law, means an enclosure, of which there was generally one in every parish or manor, in which stray cattle were put and detained until the damage done by them was paid for. Whenever a stranger's or neighbour's cattle trespass on another's lands the latter can seize them, and take them to the pound, or impound them, as it is called, *damage feasant*, and can keep them there till the expenses are repaid. There was a distinction between pound overt, or common pound, and pound covert, or close pound; in the former case the owner of the beasts could go and feed and water his cattle while impounded, and it was his duty to do so; but not in the latter case. Now it is compulsory for the impounder in all cases to supply the cattle with food, otherwise he incurs a penalty; and if impounded cattle are not sufficiently fed a stranger who feeds them may not only trespass on lands to do so, but can recover the costs from the owner of the beasts. Goods distrained, if liable to be stolen or damaged, should be deposited in pound covert. At Madresfield, near Malvern, a public pound was repaired so recently as 1888; but practically they are quite obsolete, since the law now permits a person distraining for rent to secure the distress on the premises (see Distress). In the United States estrays are generally liable to be sold for the benefit of the poor of the place where they are found, or for some other public use.

Poundal, a name sometimes used for the absolute foot pound second unit of force, which will produce in one pound a velocity of one foot per second, after acting for one second.

Poushkin. See Pushkin.

Poussin, Nicolas, a painter of great celebrity, was born at Les Andelys in Normandy in June 1594, went at the age of eighteen to Paris, and studied under Ferdinand Elle, the Fleming, Lallemand, and others, but chiefly improved himself by drawing from casts, and drawings and prints after Raphael and Giulio Romano, in the collection of M. Courtois, who accorded him access to them. After a long and hard struggle he attained the object of his desire—the means of visiting Rome. He was thirty years of age when he arrived there, and a considerable period elapsed after that before he obtained much employment. At length, however, he received several important commissions from the Cardinal Barberini, which he executed so successfully that he afterwards rapidly acquired fame and fortune. After an absence of sixteen years he returned to Paris with M. de Chanteloup, and was introduced by Cardinal Richelieu to Louis XIII., who appointed him his painter in ordinary, with apartments in the Tuileries and a small salary. But in 1643, annoyed by intrigues against him, he returned to Rome; and there, after producing a large quantity of admirable work, he died on 19th November 1665. His style is a combination of classical ideals and Renaissance tendencies; his colours have changed so as to interfere with the harmony of his pictures, whose noble designs may be admirably studied in the numerous engravings of them. The finest collection of his works is in the Louvre; but some of the best are in the National Gallery, at Dulwich, and in English private collections.—His nephew, Gaspar Dughet (1613–1675), assumed his uncle's name, and as Gaspar Poussin became famous as a landscapist, his renderings of the Roman Campagna being especially noted. He worked also in tempera and fresco. The National Gallery possesses his 'Sacrifice of Abraham.'

See works on Nicolas Poussin by St Germain, Bouchitté (1858), and Poillon (2d ed. 1875), with an article by Lady Dilke (E. F. S. Pattison) in *L'Art* (1882).

Pout. See Bib. The name Horned Pout and Bullpout are given in America to the siluroid *Amiurus*, also called Catfish (q.v.).

Poverty Bay. See Gisborne.

Powan, another name for the Gwyniad (q.v.). See Coregonus.

Powell, Baden, physicist and theologian, was born in London in 1796, was educated at Oriel College, Oxford, in 1821 became vicar of Plumstead, and in 1824 was made F.R.S. From 1827 till his death, 11th June 1860, he was Savilian professor of Geometry at Oxford. He published a history of natural philosophy (1834), treatises on the calculus (1830), optics (1833), and the undulatory theory of light (1841); but he is best known by his contribution to the *Essays and Reviews* (q.v.), and by other theological works, then regarded as dangerously 'liberal'—such as *Essays on the Plurality of Worlds* (1856), *Christianity without Judaism* (1857), *Natural and Divine Truth* (1857), and *The Order of Nature* (1859).—His son, Robert Stephenson Smyth Baden-Powell, was born 22d February 1857, and went to the Charterhouse. He joined the 13th Hussars in 1876, and served in India, Afghanistan, South Africa, Ashanti, and Matabeleland, and was promoted in 1897 to the command of the 5th Dragoon Guards. In the Transvaal war he held the town of Mafeking successfully against the Boers from 12th October 1899 to 18th May 1900; and in quite an exceptional degree was himself the guiding and inspiriting main-spring of the defence. Besides being ranked amongst national and popular heroes, he was created a major-general, and became chief of the Transvaal police. His forte is scouting, on which he has published several brilliant pamphlets, as well as on his campaigns, cavalry instruction, and pig-sticking.

Powell, John Wesley, geologist, was born at Mount Morris, New York, 24th March 1834, and became major in the civil war. He was afterwards professor of Geology in Illinois; in 1868 explored the cañon of the Colorado; in 1879 he was made director of the new Bureau of Ethnology; and in 1881 he was appointed also director of the United States Geological Survey. His works include *Exploration of the Colorado River* (1875), *The Arid Region of the United States* (1879), and *Contributions to North American Ethnology.*

Powell, Mary. See Milton.

Power is a legal term, to some extent identical in meaning with such terms as liberty, faculty, &c. A public officer is empowered to do certain acts which are not permitted to private persons. An individual, not under disability, has power to bind himself by contract, and to dispose of his property: if he chooses to settle his property he may effect the purposes of the settlement by conferring powers on himself and others; he may, for example, reserve to himself a power of revocation; he may give power to a person who takes a life interest to charge the inheritance with portions for daughters, &c. Powers of appointment are commonly used in English settlements to enable parents to appoint or distribute settled property among their children. Such powers must be exercised in good faith, and with the forms prescribed by the settler who confers them. A power of attorney is a deed whereby one person appoints another to do some act on his behalf or to represent him generally. A, for example, may make B his attorney, to manage his estate and receive the rents during A's absence abroad. Forms of such powers are given in Davidson, Prideaux, and other books of precedents; the difficult legal questions which arise in regard to powers over settled property are discussed in the treatises of Sugden and Farwell.

Power. For the Mechanical Powers, see Mechanics; and for various motive powers, see Air-engine, Gas-engine, Steam, Pneumatic Despatch, Fuel; see also Horse-power, Transmission of Power. For the 'Great Powers' of the world, see Balance of Power.

Powers, Hiram, American sculptor, was born a farmer's son at Woodstock, Vermont, July 29, 1805. While still a boy he went to Cincinnati, Ohio, where he became an apprentice to a clockmaker, and about the same time formed the acquaintance of a German sculptor, who taught him to model in clay. Subsequently he was employed for seven years making wax figures and fitting them with machinery for the Cincinnati museum. In 1835 he went to Washington, where he executed the busts of several distinguished persons. Two years later he was enabled to proceed to Italy to study his art, and he resided in Florence till his death on 27th June 1873. There he produced his statue of 'Eve,' which excited the admiration of Thorwaldsen, and in 1843 the still more popular 'Greek Slave,' of which six copies in marble, with cast copies innumerable, were produced. Of his 'Fisher Boy' (1846) three copies were ordered. Among his other works the chief were 'Proserpine,' 'Il Penseroso,' 'California,' 'America,' and busts of Washington for the state of Louisiana, of Calhoun for South Carolina, and Daniel Webster for Boston, as well as those of J. Q. Adams, Andrew Jackson, Marshall, Van Buren, and other distinguished Americans.

Poynings' Act. See Ireland, Vol. VI. p. 204.

Poynter, Sir Edward John, painter, was born in Paris, 20th March 1836, the son of Ambrose Poynter, architect, and great-grandson of Thomas Banks, sculptor, R.A. He was educated at Westminster, Brighton College, and Ipswich grammar-school. Very delicate health caused him to be sent to Madeira for the winter of 1852–53, and from this visit arose the earnest desire to become an artist. The winter of 1853–54 was spent in Rome, and here he made the acquaintance of Frederick Leighton, then a young man painting his picture of 'Cimabue,' who allowed Poynter to work in his studio, drawing from the models and drapery from which he was studying for his picture. In 1856 he went to study in Paris, and in 1860 settled finally in London. He now made many designs for stained glass, and drawings on wood for *Once a Week* and other periodicals, and for Dalziel's projected illustrated Bible. This led him to study Egyptian art; and in 1864 he began his large 'Israel in Egypt' (1867). His water-colours are numerous, and he was elected to the Royal Water Colour Society in 1883. In 1868 he was made an A.R.A., in 1876 an R.A. In 1871 he was appointed Slade professor, and in 1876 Director for Art and Principal of the training-schools at South Kensington—appointments which in 1881 he resigned as interfering too seriously with his time for painting. Among the most important of his works are 'The Catapult' (1868); 'The Prodigal Son' (1869); 'The Ibis Girl' (1871); 'The Festival' and 'The Golden Age' (1875); 'Zenobia' (1876); 'A Visit to Æsculapius' (1880, now at South Kensington); 'The Ides of March' (1883); 'Outward Bound' (1886); 'A Corner of the Market Place' (1887); 'Under the Sea Wall' (1888); 'A Corner in the Villa' (1889); 'The Visit of the Queen of Sheba to Solomon' (1890); and 'Perseus and Andromeda' (1872), 'The Dragon of Wantley' (1873), 'Atalanta's Race' (1876), 'Nausicaa and her Maidens' (1879), all painted for the Earl of Wharncliffe, and now at Wortley Hall. In the years 1869–70 he did the cartoons for a large mosaic of St George in the central lobby in the Houses of Parliament. In 1882–84 he painted designs for the decoration of the dome of St Paul's, and cartoons (full size) for one portion of the dome. Of portraits may be

mentioned those of Lord Ripon (1886), Sir Gerald Graham (1886), and the Earl of Harewood (1888). In 1894 he became director of the National Gallery. In 1896 he was made P.R.A. and knighted. See the article by Cosmo Monkhouse in the *Art Journal* for Easter 1897.

Pozzo di Borgo, Carlo Andrea, Count, was born near Ajaccio in Corsica, 8th March 1764, and was educated at the university of Pisa. An advocate in Ajaccio, in 1790 he joined Paoli (q.v.), becoming thenceforth the enemy instead of the friend of Bonaparte. Paoli made him president of the Corsican council of state in 1794, and subsequently secretary of state; but in 1796 he was obliged to seek safety from the Bonapartes in London. Two years later he went to Vienna and effected an alliance of Austria and Russia against France. In 1803 he entered the Russian service as a councillor of state, and was employed in many important diplomatic missions. After the battle of Jena he laboured to unite Napoleon's enemies against him, and again in 1809 and 1812. He also effected the seduction of Bernadotte, crown-prince of Sweden, from the Napoleonic cause; and after the allies had driven Napoleon across the Rhine, Pozzo di Borgo drew up the famous declaration, 'that the allies made war not on France, but on Napoleon.' It was he who urged the allies to march on Paris. He represented Russia at Paris and the Congress of Vienna, at the Congress of Verona, and in London, but retired from public life in 1839, and settled in Paris, where he died, 15th February 1842. See *Notice Biographique* by Vuhrer (Paris, 1842).

Pozzuoli, a city of Southern Italy, on the Bay of Naples, 7 miles W. of Naples, with which it is connected by tramway, a city particularly interesting from its numerous memorials of classic ages. Its cathedral was the Temple of Augustus. The Temple of Serapis or Serapeum had a rectangular colonnade of twenty-four pillars, surrounding a round temple with sixteen pillars. Some have alleged that the outer enclosure surrounded a market-place. Some of the pillars still standing are much eaten into by the lithodomus mollusc (see Boring Animals), showing that this volcanic coast was for a considerable time submerged to a depth of 13 feet beneath the sea, and subsequently upheaved again. Part of the ruins are still under the sea-level. There are the remains of an amphitheatre in which Nero fought as a gladiator, and which could seat 30,000 spectators; in it wild beasts refused to injure St Januarius and his companions, thrown to them by persecutors. There are also remains of temples to Diana and Neptune, and of the ancient harbour of Puteoli. Behind the town is the Solfatara (anciently called *Forum Vulcani*, as being the entrance to Vulcan's forge), a half-extinct volcano, from which issue currents of hot sulphureous gases, inhaled by sufferers with chest complaints, and springs of saline water, used as a remedy for cutaneous diseases. In the neighbourhood are Avernus (q.v.); the royal (Italian) hunting-lodge Astoni; Lake Lucrinus, celebrated for its oysters; the ruins of Baiæ (q.v.) and Cumæ (q.v.); and the Lake of Agnano, with the Grotta del Cane (q.v.). Of a very different interest are the military engineering works, the Stabilimento Armstrong, a little to the west of Pozzuoli; this is a branch of the famous Armstrong works at Elswick, near Newcastle, established here (1888–90) with the support of the Italian government. Pop. 11,967. The ancient *Puteoli* was made a Roman colony in 194 B.C. Towards the end of the republican period it became virtually the port of Rome, and during the empire was the first emporium of commerce in Italy. Puteoli was destroyed by Alaric, Genseric, and Totila, and, though rebuilt by the Byzantine Greeks, it was sacked by the Saracens (10th century) and the Turks (1550), and ruined by earthquakes (1198 and 1538). St Paul landed there.—For the volcanic earth found here and elsewhere, and called *Pozzuolana* or *Puzzolana*, see Cements.

Practice, in Arithmetic, is the name given to a method, or rather a system of expedients, for shortening or avoiding the operation of compound multiplication. The nature of the expedients will be best understood by an example: Suppose that the price of 64,875 articles at £2 17s. 6d. is required. It is obvious that the price, at £1, would be £64,875; therefore, at £2, it is £129,750; at 10s. it is the half of that at £1, viz. £32,437, 10s.; at 5s., the half of this last sum, or £16,218, 15s.; and at 2s. 6d., the half of this, or £8109, 7s. 6d. The sum of these partial prices gives the whole price.

Praed, Winthrop Mackworth (1802–39), was born 26th July 1802, at 35 John Street, Bedford Row, London. His name Winthrop came from American connections; Mackworth had been the surname of his father, who was a serjeant-at-law. After some training at a private school he went to Eton. Here he was more famous for literature than athletics, and was one of the most brilliant contributors to the well known *Etonian*. From Eton he passed in 1821 to Trinity College, Cambridge, distinguishing himself rapidly in Greek and Latin verse, and cultivating the lighter letters with increased success in Charles Knight's *Quarterly Magazine*, where he had for co-mates De Quincey, Macaulay, Moultrie, H. N. Coleridge, and others. In 1825, having won many college honours, he became tutor to the son of the Marquis of Ailesbury, intending to qualify for the bar, to which four years later he was called. In November 1830 he entered parliament for St Germains. He subsequently became member for Great Yarmouth, and later for Aylesbury, which he represented at his death on 15th July 1839. From 1834 to 1835 he was secretary to the Board of Control.

But for his short life Praed might possibly have been successful as an orator and politician. As it is, he derives his existing reputation from the finished and facile verses which he wrote almost from his childhood. He is the Coryphæus of the little band of rhymers whom criticism, according to its taste and fancy, either dignifies or stigmatises as writers of *vers de société*—a term in its stricter sense applied to those pieces which treat only of the sayings and doings of the fashionable world. The majority of Praed's efforts belong exclusively to this class; and in this line his note is so individual, his rhythm so brilliant, and his wit so bright, that it has hitherto been found more easy to imitate than to excel him. A typical example of this side of his talent is the poem called *A Letter of Advice*. But he is also admirable in a kind of metrical *genre*-painting—e.g. *The Vicar*, which, in the opinion of many, reaches a higher poetical elevation; while in *The Red Fisherman*, *Sir Nicholas*, and one or two other pieces, he not unskilfully emulates the manner of Macaulay and Hood. His characteristics as a verse-writer are point, elegance, and vivacity; it is his defect that these excellent gifts are but seldom relieved by any graver note. His collected verses, popular in America long before they were gathered together in England, appeared in 1864 in two volumes, with a memoir by the Rev. Derwent Coleridge; in 1887 followed his prose essays; and in 1888 his nephew, Sir George Young, edited his political poems. The best modern study of Praed is to be found in Saintsbury's *Essays in English Literature* (1890).

Præfect, a common name applicable to various Roman functionaries. The most important was the *Præfectus urbi*, or warden of the city, whose office existed at an early period of Roman history, but was revived under Augustus, with new and greatly altered and extended authority, including the whole powers necessary for the maintenance of peace and order in the city, and an extensive jurisdiction civil and criminal. The *Præfectus prætorio* was the commander of the troops that guarded the emperor's person.

Præfloration. See ÆSTIVATION.

Præfoliation. See VERNATION.

Præmonstratensians. See PREMONSTRATENSIANS.

Præmunire, the name given, in English law, to a species of offence of the nature of a contempt against the sovereign and his government, and punishable with forfeiture and imprisonment. The name is derived from the first words (*præmunire* or *præmonere facias*) of a writ originally introduced for the purpose of repressing papal encroachments on the power of the crown. The attacks of the popes on the rights of private patrons, by bestowing bishoprics, abbacies, &c. on favourites, often aliens, and the pope's insisting on deciding in his curia cases that ought to have been tried in the king's courts, were especially unpopular in England, and were the immediate cause of various statutes of præmunire. Severe penalties were imposed on those who gave or sought to enforce obedience to the papal encroachments. The Statute of Provisors (1350; see ENGLAND, CHURCH OF, Vol. IV. p. 357) was an early act of this sort; the first act called Præmunire was passed in 1353; but the name of Præmunire is specially used of an act of 1393, in which Richard II. re-enacted and strengthened the statute of Edward III. Under Elizabeth it was made a breach of the Statute of Præmunire to refuse the oath of supremacy. By later statutes a number of offences of a miscellaneous description were rendered liable to the penalties of a præmunire, as (by 6 Anne, chap. 7) the asserting that any person, other than according to the Acts of Settlement and Union, has any right to the throne of these kingdoms. The knowingly and wilfully solemnising, assisting, or being present at any marriage forbidden by the Royal Marriage Act is declared by 12 Geo. III. chap. 11 to infer a præmunire.

Prænesté. See PALESTRINA.

Prætor was, among the ancient Romans, the title given to the consuls as leaders of the armies of the state; but it was specially employed to designate a magistrate whose powers were scarcely inferior to those of a consul. The prætorship, in this specific sense of the term, was first instituted in 366 B.C., as a compensation to the patricians for being obliged to share with the plebeians the honours of consulship. It was virtually a third consulship; the prætor was entitled *collega consulibus;* he was elected by the same auspices and at the same comitia. For nearly thirty years patricians alone were eligible for the office; but in 337 B.C. the plebeians made good their right to it also. The prætor's functions were chiefly judicial. Though he sometimes commanded armies, and, in the absence of the consuls, exercised consular authority within the city, yet his principal business was the administration of justice both in matters civil and criminal; and to the edicts of successive prætors the Roman law owes much of its development and improvement. Originally there was only one prætor; but as the city and state increased, and their relations with other nations became more complicated, others were added. In 246 B.C. a second prætor was appointed, to settle disputes that might arise between Romans and foreigners temporarily resident at Rome, for trading or other purposes, hence called *prætor peregrinus* ('foreign prætor'), to distinguish him from the original *prætor urbanus* ('city prætor'). In 227 two new prætors were appointed, to administer affairs in Sicily and Sardinia; and in 197 two more for the Spanish provinces, or six in all. Sulla increased the number to eight, and Julius Cæsar to sixteen. Augustus reduced the number to twelve; but at a later period we read of eighteen, if not more. The city prætorship was reckoned the highest; and after a person had filled this office he sometimes received the administration of a province with the title of *proprætor* or *proconsul.*

Prætorian Guard (Lat. *Prætoriæ Cohortes* and *Prætoriani*), a body of soldiers organised for the purpose of protecting the person and maintaining the power of the emperors. We read of a *prætoria cohors*, or select guard of the most valiant soldiers, attached to the person of Scipio Africanus, but it is to Augustus that the institution of them as a separate force was owing. He formed nine or ten cohorts, each consisting of a thousand men (horse and foot), but kept only three of them in Rome, the rest being dispersed in cities not far off. Tiberius, however, assembled the nine cohorts at the capital in a permanent camp, and Vitellius increased their number to sixteen. The Prætorians served at first for twelve, and afterwards for sixteen years; they received double pay; the privates were held equal in rank to the centurions in the regular army, and on their retirement each received 20,000 sesterces. They soon acquired a dangerous power, which they exercised in the most unscrupulous manner, deposing and elevating emperors at their pleasure. Aspirants for the imperial dignity found it advisable, and even necessary, to bribe them largely; while those who acquired that dignity without their assistance were accustomed on their accession to purchase their favour by liberal donations. The Prætorians, however, had no political or ambitious views; they were simply an insolent and rapacious soldiery, fond of substantial gratifications, and careless how they got them. After the death of Pertinax (193 A.D.) they actually sold 'the purple' for a sum of money to Didius Julianus; but in the same year their peculiar organisation was entirely broken up by Severus, who formed new cohorts altogether out of the best legions serving on the frontiers, which he increased to four times the number of the old. After several other changes Constantine (312) dispersed them among his regular legions.

Pragmatic Sanction (sometimes *Pragmatic Rescript*), a solemn ordinance or decree of the head of a kingdom relating either to church or state affairs. The term originated in the Byzantine empire, and signified a public and solemn decree by a prince (*pragmatikos*, 'business-like,' later, 'versed in affairs,' 'official'), as distinguished from the simple rescript, which was a declaration of law in answer to a question propounded by an individual. This name is given to several important treaties, of which the principal are (1) that of St Louis in 1269 and (2) that of Charles VII. in 1437, in both of which the rights of the Gallican Church (q.v.) were asserted; (3) the instrument which settled the empire of Germany in the House of Austria (1439); (4) the ordinance by which Charles VI., emperor of Germany, having no male issue, settled his dominions on his daughter, the Archduchess Maria Theresa; (5) the settlement of the succession of the kingdom of Naples, which was ceded by Charles III. of Spain, in 1759, to his third son and his descendants.

Prague (Ger. *Prag*, Czech *Praha*), the capital of Bohemia, and the third largest town of Austria-Hungary, is situated at the base and on the slope of the hills which skirt both sides of the isleted Moldau, 217 miles by rail NNW. of Vienna and 118 SSE. of Dresden. It offers a highly picturesque appearance from the beauty of its site, and the numerous lofty towers (more than seventy in number) which rise above the many noble palaces, public buildings, and bridges of the city. The fortifications have been gradually demolished since 1866. The royal Burg, on the Hradschin (240 feet), the ancient residence of the Dukes of Bohemia, dates mainly now from the 16th and 17th centuries, and has 440 rooms. The neighbouring cathedral of St Vitus (1344) is still unfinished, though building was resumed in 1867. Here are the splendid royal mausoleum (1589) and the shrine (1736) of St John of Nepomuk (q.v.), containing 1½ ton of silver. Of forty-seven other Catholic churches the chief are the domed Jesuit church of St Nicolas, with its lavish decorations, and the Teyn church (1407), the old Hussite church, with the grave of Tycho Brahé, and its marble statues of the Slavonic martyrs, Cyril and Methodius. Of five bridges and two railway viaducts the most striking is the Karlsbrücke (1357–1503), 543 yards long, with gate-towers at either end, and statues of John of Nepomuk and other saints. It was greatly damaged by flood in September 1890, but has since been restored. Other noteworthy objects are the town-hall (1381–1884), the Pulverturm (1475), the new Czech Theatre (1883), the old Jewish graveyard, the Theresa Institution for Ladies, the vast Czerni Palace (now used as barracks), the Picture-gallery, and the Premonstratensian monastery of Strahow. Prague has, besides, numerous public gardens and walks in the suburbs, with several royal and noble parks open to the public in the vicinity of the city. The suburb of Karolinenthal, which is traversed by the great viaduct of the railway, and is of modern growth, has some fine buildings, numerous gardens, barracks, and manufacturing establishments; and somewhat farther north is the great botanical garden, with the neighbouring public walks on the Moldau. The university, founded in 1348, had 10,000 students at the beginning of the 15th century; but subsequently it had a long period of decay. It received a new constitution in 1881, having now two co-ordinate sides or sections, one German and one Czech, with respectively 156 and 140 teachers, and 1470 and 2361 students. It possesses a library of 195,000 volumes and 3800 manuscripts, a fine observatory, museums of zoology and anatomy, a botanical garden, &c. The manufactures include machinery, chemicals, leather, cotton, linen, gloves, beer, spirits, &c. Prague is the great centre of the commerce of Bohemia, and the seat of an important transit trade. Pop. with suburbs (1880) 293,822; (1890) 310,483; of the town proper (1890) 182,530, of whom 81 per cent. were Czechs, 2 per cent. Protestants, and 10 per cent. Jews.

History.—Prague was founded, according to popular tradition, in 722 by the Duchess Libussa, but really by German settlers about 1100. In the 14th century its munificently endowed university brought foreigners to it from every part; but in 1424 Prague was conquered and almost destroyed by the Hussites, who had made a successful stand against the Emperor Sigismund's army. In the Thirty Years' War it suffered severely, and in 1620 the battle was fought at the Weissenberg, near the city, in which the Elector-Palatine, Frederick V. (q.v.), was completely defeated, and compelled to renounce his assumed crown. Swedes and Imperialists successively gained possession of the town during the war; and a century later it again fell into the hands of different victors, having been compelled in 1744 to capitulate to Frederick the Great, who here on 6th May 1757 defeated 60,000 Austrians under Prince Charles of Lorraine. Until the downfall of Napoleon the city continued to suffer more or less directly from the troubles in which the House of Austria was involved. Since then, however, it has made rapid strides, and enjoyed prosperity and quiet, except in 1848, when the meeting of the Slavonic Congress within its walls called forth such strongly marked democratic demonstrations on the part of the supporters of Panslavism (q.v.) that the Austrian government dissolved the conclave, and restored quiet by the summary method of causing the old and new town to be bombarded for two days. In 1866 Prague was occupied bloodlessly by the Prussians, who here on 23d August concluded a treaty with Austria. The jealousy subsisting between the Czech and the German population was strongly accentuated on the occasion of the Exhibition of 1891. See *Statistisches Handbuch der Hauptstadt Prag* (3 vols. 1882–86).

Praia Grande. See RIO DE JANEIRO.

Prairie (Fr., 'meadow') was the name given by the early French explorers of the northern portion of the Mississippi Valley, North America, to the vast fertile and treeless plains which extend from Western Ohio and Southern Michigan across the states of Indiana, Illinois, Missouri, Arkansas, Iowa, Kansas, Nebraska, and North and South Dakota, including the southern portions of Wisconsin and Minnesota. The prairie region also extends northward into Canadian territory. These great plains or savannas are sometimes flat, but oftener rolling like the long swells of the ocean, and rise in gradual elevation from 300 to 1500 feet above the sea. See AMERICA, Vol. I. p. 215.

Prairie Dog (*Cynomys Ludovicianus*) is a small rodent closely allied to the European Marmot (q.v.); these animals have received their vernacular name on account of the barking sound which they utter. They live associated together in colonies consisting of numerous burrows excavated by the animals themselves; their range is entirely

Prairie Dog (*Cynomys Ludovicianus*).

restricted to the parks and plains of the Rocky Mountain plateau region in North America, and there appear to be two distinct varieties. They have been popularly supposed to share their habitations, and to live in friendly relations, with rattlesnakes and owls. As regards the rattlesnake, it is more than probable that its occurrence in the burrows of the rodent is to be explained by a desire to make a meal of its neighbours, while the owl may have a similar purpose in view; it is also possible in both cases that the burrows may be

merely utilised as a temporary hiding-place. The Prairie Marmot is rather larger than a large rat, and is of a brownish-gray colour, the under surface grayish white.

Prairie Hen. See GROUSE.

Prâkrit is the collective name of those languages or dialects which are immediately derived from, or stand in an immediate relation to, Sanskrit (q.v.). See also INDIA, Vol. VI. p. 102.

Prase, a rarish green variety of Quartz (q.v.).

Pratique is, strictly, a limited quarantine. A ship is said to have performed pratique when her captain has convinced the authorities of a port that his ship is free from contagious disease; and he is thereupon permitted to open trade and communication with the shore.

Prato (often called *Prato in Toscana*), a walled town of Italy, by rail 10½ miles SE. of Pistoia and 11 NW. of Florence. It has a citadel and a cathedral with frescoes by Filippo Lippi, though the see has been united with that of Pistoia since 1653. There are manufactures of straw-plait, cloth, and paper and brass works. Pop. 15,510.

Prawn, a name applied indiscriminately to crustaceans belonging to the genera Palæmon, Pandalus, and Hippolyte. They are nearly allied to shrimps and lobsters, are mostly but not exclusively marine, and vary in size from a couple of inches to over a foot in some tropical forms. There are many species; thus, *Palæmon squilla, Pandalus annulicornis,* and *Hippolyte spinus* are common in the Firth of Forth, while others abound elsewhere. Many of them are semi-transparent, and exhibit very fine colours; they are also very active creatures, and most interesting inmates of an aquarium, but are excessively voracious, and apt to make great havoc among its other inhabitants. They are common on the British coasts, although not so abundant as shrimps, and are generally taken in the vicinity of rocks at a little distance from the shore. They may be caught in putting nets or in osier baskets, like those used for trapping lobsters. They are esteemed for eating even more highly than the shrimp. For illustration, see CRUSTACEA.

Praxinoscope. See ZOETROPE.

Praxit'eles, one of the greatest sculptors of ancient Greece, of whose life little is known, except that he was a citizen of Athens, and lived in the 4th century B.C. His principal works—nearly all of which have perished—were statues of Aphrodite (at Cos, Cnidus, Thespiæ, and elsewhere, of which that of Cnidus was the most famous), Eros (at Thespiæ), Dionysus (at Elis, Athens, Megara, and other places), Apollo (the best representing Apollo as the Python-slayer), and Hermes carrying Dionysus (found at Olympia in 1877). Feminine beauty and Bacchic pleasures were his favourite subjects; and in his treatment of these he displayed unrivalled sweetness, grace, and naturalness. His gods and goddesses were not very divine, but they were ideal figures of the fairest earthly loveliness.

Prayer is a universally acknowledged part of the worship due to God; not merely petition, but according to the New Testament models and Christian usage, praise, adoration, confession of sin, and thankful acknowledgment of mercies received. It is a simple and natural expression of dependence, which seems almost necessarily to follow from a belief in the existence of a god. Accordingly we find it both where the object of worship is one Supreme Being and in systems of polytheism. According to the Christian system, however, prayer is not the mere spontaneous approach of man to God in the endeavour to appease his wrath, to win his favour, or to obtain from him any blessing; but the right to approach him in prayer, and the warrant to expect advantage in doing so, rest on the revelation of his own will. Nor is any truth more indisputably taught in the Bible, or more frequently brought into view, both in the Old and in the New Testament, than that God is the hearer of prayer.

But a difficulty presents itself in respect to what may be called the theory of prayer. How can prayer be supposed to influence the divine mind or will? How can a belief in its power be reconciled with any view of the divine decrees, from the most absolute doctrine of predestination to the most modified scheme which recognises the Creator as supreme in the universe? Such questions bring up the same difficulty which attends all other questions of the relations between the human will and the divine, the freedom of man and the sovereignty of God. But whatever seeming inconsistencies may be implied in speculation concerning them, the necessity of prayer and the power of prayer are acknowledged equally by men of the most opposite views; and generally with an acknowledgment of the inability of the human mind to solve some of the problems which are thus presented to it. The extreme predestinarian includes prayer among the means decreed of God along with the end to which it contributes. And whilst prayer is regarded by all Christians as of great value in its reflex influence on the feelings of the worshipper, this is scarcely ever stated as its whole value. It is held by Christians in general that the only true way of access to God is through the mediation of Jesus Christ; and that prayer can be truly made, in faith and for things agreeable to God's will, only by the help of the Holy Spirit. The Protestant churches all hold that prayer is to be made to God alone; but in the Roman Catholic Church, and to some extent in the oriental churches, prayer of a kind is made also to saints, the Virgin Mary, and angels. But as the worship (*douleia*) of the saints differs from that (*latreia*) offered to God, so the invocation of saints and angels is not for the purpose of obtaining mercy or grace from them directly, but in order to ask their prayers or intercession with God on our behalf. For this practice Catholics rely not on the direct authority of Scripture, but on the unwritten word of God conveyed by tradition from very early times. The inscriptions in the catacombs prove that the church of the first centuries invoked the saints; and the famous fathers of the 4th century expressly insist on such invocation. Protestants hold that prayer ought to be conducted in a language known to the worshippers. The Church of Rome has, on the contrary, maintained the general use of the Latin language, even though that language is unknown to most of the worshippers.

Forms of prayer for public use grew up in the earliest times, naturally and inevitably: the Lord's Prayer being doubtless regarded as a warrant and a model. Apparently the most primitive collection is that in the eighth book of the pseudo-Clementine *Apostolic Constitutions* (q.v.). The prayers in connection with the celebration of the eucharist in the Greek and Roman communions are dealt with at LITURGY. The most important post-Reformation collection of prayers, that of the Anglican Church, is dealt with in the next article. But most of the leading reformers prepared prayer-books. Luther's date from 1523 and 1526, Calvin's from 1538 (from Strasburg) and 1541 (from Geneva), John Knox's for the Church of Scotland (based on that of Geneva) from 1554. The growth of Puritan feeling in Britain led the Nonconformists, Presbyterians, and others to underrate the advantages of set forms of prayer, and to exalt the value of what is assumed

to be the spontaneous utterance of the heart. And ultimately it became usual to regard liturgical forms as essentially Episcopalian and un-Presbyterian, though the forms of church government are irrelevant to the question as to the best mode of guiding congregational prayer. Since 1857 a section of the Church of Scotland has made tentative efforts towards securing the use of printed forms of public prayer, without wholly excluding extempore prayer (see LEE, ROBERT). In 1888 the Assembly sanctioned a book of prayer for the use of soldiers, sailors, and others; and the *Euchologion*, prepared by the Church Service Society, has passed through several editions. In the United States liturgical forms of prayer have been almost wholly disused by all the churches save the Episcopal, Lutheran, German and Dutch Reformed, and Moravian churches. But since the middle of the 19th century there has been a manifest tendency to aim at increased dignity in Presbyterian prayer, and to bridge over the gulf that used to separate Presbyterians from the ancient church in the forms of public approach to the mercy-seat of God. Professor Shields of Princeton's *Presbyterian Book of Common Prayer* is simply the Anglican prayer-book with the alterations proposed by the Presbyterians at the Savoy Conference (q.v.).

PRAYER FOR THE DEAD, in the Roman Catholic, Greek, and other oriental churches, is offered with the intention and expectation of obtaining for the souls of the deceased an alleviation of their supposed sufferings after death on account of venial sins, or of the penalty of mortal sins, remitted but not fully atoned for during life. The practice of praying for the dead is usually associated with the doctrine of Purgatory (q.v.) or with the belief in a progressive intermediate state (see HELL). It being once supposed that relations subsist between the two worlds, that their members may mutually assist each other, it is almost a necessary consequence of the doctrine of purgatory that the living ought to pray for the relief of their suffering brethren beyond the grave. It seems certain that some such doctrine existed in most of the ancient religions. Its existence among the Jews is attested by the well-known assurance in 2 Maccabees, chap. xii., that 'it is a holy and wholesome thought to pray for the dead, that they may be loosed from their sins.' Catholics contend that the doctrine as well as the practice is equally recognisable in the early Christian church. They rely on the parable of Lazarus and the rich man (Luke, xvi. 19–31), as establishing the intercommunion of this earth with the world beyond the grave; and on Matt. xii. 32, as proving the remissibility of sin or of punishment after death; as well as on 1 Cor. xv. 29, as attesting the actual practice among the first Christians of performing or undergoing certain ministrations in behalf of the dead. The Fathers of the 2d, 3d, and still more of the 4th and following centuries frequently allude to such prayers, as Clement of Alexandria, Tertullian, St Cyprian, and especially St John Chrysostom, Cyril of Jerusalem, and St Augustine. The liturgies, too, of all the rites without exception contain prayers for the dead; and the sepulchral inscriptions from the catacombs, which reach in their range from the 1st to the 5th century, contain frequent prayers in even greater variety. In the services of the mediæval and later church prayers for the dead form a prominent and striking element (see REQUIEM). The Protestant churches without exception repudiated the practice. In the burial service of Edward VI.'s First Common Prayer-book some prayers for the deceased were retained; but they were expunged from the Second Book; and no trace is to be found in that sanctioned under Elizabeth. Still it is not expressly prohibited, and it is cherished as a private and pious aspiration by not a few within the modern Church of England, as, in Coleridge's phrase, 'something between prayer and wish—an act of natural piety sublimed by Christian hope.'

On the doctrine of prayer, see Bickersteth, *Treatise on Prayer* (1856); Canon Liddon, *Some Elements of Religion* (1872); Newman Hall, *Prayer: its Reasonableness and Efficacy* (1875); Jellett, *The Efficacy of Prayer* (Donellan Lecture, 1877); the treatises on Apologetics, and manuals of Theology. On prayer for the dead, see Plumptre, *The Spirits in Prison* (1884); Luckock, *After Death* (1879), and *The Intermediate State* (1890). For modern scientific objections, see Romanes, *Christian Prayer and General Laws* (1874); Tyndall's British Association lecture (repub. 1874); and a series of articles in connection with Tyndall's 'Prayer Test' in *Contemp. Rev.*, vols. xx.–xxii., by Tyndall, Galton, and others, with answers by M'Cosh, the Duke of Argyll, and others. For other questions connected with prayer, see the articles AVE, PATERNOSTER, KNEELING, ROSARY, SAINTS, FAITH-HEALING.

Prayer, BOOK OF COMMON. By this name are known the service-book of the Church of England and the corresponding formularies of other Episcopal churches which have either been derived from the Church of England or largely influenced by it, such as the Episcopal Church of the United States of America, the Church of Ireland, and the Episcopal Church in Scotland. The full title of the English Book of Common Prayer (viz. 'The Book of Common Prayer, and Administration of the Sacraments, and other Rites and Ceremonies of the Church, according to the use of the Church of England: together with the Psalter, or Psalms of David, pointed as they are to be sung or said in Churches; and the Form or Manner of Making, Ordaining, and Consecrating of Bishops, Priests, and Deacons') declares the varied character of its contents, and indicates that the volume includes many services besides those (viz. Morning and Evening Prayer) to which the term 'Common Prayer' is strictly applied in the technical language of liturgiologists. Thus it will be seen that this compendious service-book embraces elements corresponding to parts not only of the Breviary (q.v.), but also of the Missal (q.v.), the Pontifical (q.v.), and the Manual of the mediæval English Church, from which they were chiefly derived.

It is not our province here to consider generally the influences which operated to bring about the Reformation in England. It must suffice to observe that in regard to liturgical changes the main objects aimed at by the English Reformers were (1) to rid the services of features which were regarded as the outcome of superstition and ignorance (e.g. the invocation of saints, unhistorical and absurd legends read among the 'lessons,' &c.); (2) to introduce a more continuous and more extensive reading of Holy Scripture in the public services; and (3) to present all the services of the church in a language 'understanded of the people.' The publication in 1890 (from a MS. in the British Museum) of the draft, revised by Cranmer, of a reformed Latin breviary shows us how much the mind of the most influential of the English reformers had been influenced by the corresponding labours of Cardinal Quignon (see BREVIARY). The first and second of the objects above referred to were aimed at in this projected work of Cranmer, which was probably abandoned because the bolder design of giving the people all the services of the church in their native tongue had begun to be contemplated. Parts of the preface of Quignon's breviary were transferred, with some modifications, to the preface of the First Prayer-book, and still appear in the prefatory remarks entitled, in the present prayer-book, 'Concerning the Service of the Church.'

The first vernacular service put forth by authority for public use was the Litany (1544), differing

in but few particulars from the form still to be found in the prayer-book. On the death of Henry VIII. liturgical reformation was less impeded, the advisers of the young king being favourable to change. The administration of the cup to the laity having been sanctioned by convocation and enjoined by parliament (1 Edward VI. chap. 1), a form for communion 'in both kinds,' in the English tongue, to be *added to* the Latin mass, was issued in 1548. But this form served only a temporary purpose, for in the following year (1549) was published and authorised the complete prayer-book in English, known as the First Prayer-book of Edward VI. In this book, with singular ability, attaining at times the level of genius, Cranmer and his coadjutors translated and adapted the breviary services of Matins, Lauds, and Prime, so as to construct the 'Morning Prayer' of the Book of Common Prayer; while, in a similar manner, Vespers and Compline were brought into the form of the 'Evening Prayer.' The English services were shortened chiefly by the great reduction of the number of psalms to be 'sung or said' daily. The lectionary was so arranged that the greater portion of the Old Testament was read through systematically in the course of the year, while the whole of the New Testament (with the exception of the Apocalypse) was read through thrice. The old English missals formed the basis of the English communion service, but therewith were combined the new features which had appeared in the 'Order of the Communion' (1548). The other services, as those for baptism, matrimony, burial, &c., were similarly framed, with much discrimination, from the corresponding mediæval services. The ecclesiastical books of the Eastern Church were not wholly unknown to the Reformers, as is testified to by their adoption of the so-called 'Prayer of St Chrysostom,' and by the unquestionable fact that the Athanasian Creed was translated by them from a Greek and not a Latin text. Occasionally the revisers did not scruple to adopt features from more modern sources (e.g. the *Pia Deliberatio* of the reforming Archbishop Hermann of Cologne). The liturgical revision of 1549 was conducted in a spirit at once conservative and critical, and is marked by a singular combination of independence with reverence for the past.

Owing partly to home influences and partly to the influence of foreign reformers (many of whom were then resident in England, including Bucer, regius professor of Divinity at Cambridge, and Peter Martyr, regius professor of Divinity at Oxford), Cranmer and his associates ceased to be content with the doctrinal colouring of the First Prayer-book; and in 1552 there appeared a revised book (the Second Prayer-book of Edward VI.), marked by many changes mainly favourable to more Protestant views. As a characteristic example may be cited the change made in the words used at the communion in delivering the consecrated elements. In 1549 the words ran 'The body of our Lord Jesus Christ, which was given for thee, preserve thy body and soul unto everlasting life,' 'The blood of our Lord Jesus Christ,' &c. In 1552 these words were expunged, and for them were substituted 'Take and eat this in remembrance that Christ died for thee, and feed on him in thy heart by faith, with thanksgiving,' 'Drink this in remembrance,' &c. In a similar spirit the 'Invocation' of the Holy Ghost on the elements—'that they be unto us the body and blood of thy most dearly beloved Son'—was removed (together with use of the sign of the cross) from the prayer of consecration. From the baptismal service the exorcism, trine immersion, anointing, and the use of the chrisom (or white robe) were omitted. From the burial service prayers for the dead were removed. The vestments of priests and deacons were reduced to the surplice, and those of the bishop to a rochette, for all ministrations. Among changes then made, though of little or no doctrinal significance, may be mentioned the addition of the sentences, introductory address, general confession, and absolution to morning and evening prayer, and of the decalogue and responses to the communion service.

On the accession of Queen Elizabeth the personal ecclesiastical sentiments of that masterful monarch made themselves sensibly felt. In the newly-revised prayer-book of 1559 (Elizabeth's Prayer-book) very few changes were made, but they pointed in one direction. The vestments and ornaments of the prayer-book of 1549 were again enjoined; in the litany the words 'From the tyranny of the bishop of Rome and all his detestable enormities, good Lord, deliver us' were omitted; in the communion service the words of Edward's two books at the delivery of the elements were combined in the form still in use; the declaration concerning kneeling (the so-called 'Black Rubric') appended to the communion service of Edward VI.'s Second Prayer-book was omitted.

During Elizabeth's reign the Puritan and Calvinist party within the church increased in strength, and the hopes of its members were raised high on the accession of James I., educated as he had been in Scotland under Presbyterian influence. Not many days after the king's accession he was presented by the Puritans with a petition, called, from the great number of signatures attached to it, the Millenary Petition. This craved for the removal of 'offences' from the prayer-book. The petitioners further suggested a conference, and to this suggestion the king acceded, the outcome being the Hampton Court Conference (January 14, 16, and 18, 1604), so called from its place of meeting. The issue of this conference was deeply disappointing to the Puritan party. The alterations made were comparatively few and unimportant: certain chapters of the Apocrypha (Tobit, v. vi. and vii., and Dan. xiv.) were removed from the lectionary; the words 'or remission of sins' were added as explanatory of the word 'absolution' at morning prayer; a prayer for the queen and royal family, together with some special thanksgivings, as 'for rain,' 'for fair weather,' &c., were inserted. The only changes of much significance were (1) the addition to the catechism of the part treating of the sacraments (attributed to the pen of Overall, Dean of St Paul's, and certainly not favourable to the views of the Puritans), and (2) the insistence on baptism being administered by the 'lawful minister,' as the church's order; while the *validity* of baptism administered by any person using water and the prescribed form of words is still implied in the text of the service. It is worth observing that, while to the three earlier revisions and the last revision (1662) were given parliamentary authority (2 and 3 Edw. VI. chap. 1; 5 and 6 Edw. VI. chap. 1; 1 Eliz. chap. 2; 14 Carol. II. chap. 4), James considered that the authority of the crown was sufficient to introduce changes, which he was careful to style 'explanations,' as though they were not additions.

The Book of Common Prayer 'for the use of the Church of Scotland' (1637), commonly known as 'Laud's Prayer-book,' was a revision of the English prayer-book, in the construction of which Wedderburn, Bishop of Dunblane, and Maxwell, Bishop of Ross, were chiefly concerned, their English advisers being Laud, Wren, and Juxon. It is mainly remarkable for its reverting in the communion service to some of the characteristic features of the First Prayer-book of Edward VI.—e.g. (1) the 'Invocation,' and (2) the commemoration of the faithful departed. It is also interesting to notice that the Scottish revision anticipated and happily met

some of the difficulties that have since been raised in respect to the Athanasian Creed. The prose psalter of this prayer-book was taken from the authorised version of the Bible. The word 'presbyter' was used instead of 'priest.' The calendar records the names of certain Scottish saints—e.g. Columba, Ninian, Serf, Queen Margaret, &c.

The attempt to force this prayer-book upon the Scottish people in an arbitrary manner, emphasised, as it was, by the riot in St Giles' Cathedral, Edinburgh, on the occasion of its first being read (23d July 1637), and the national uprising that followed are parts of civil history. It should be added that the Scottish prayer-book, which had seemed to be strangled at its birth, was twenty-four years afterwards among the most potent influences affecting the revision which has brought the English prayer-book to its present shape.

During the years of the Great Rebellion it was enacted by an ordinance of parliament (January 3, 1645) that the 'Westminster Directory for the Public Worship of God' should take the place of the prayer-book; and a subsequent ordinance of the same year (August 23) made the use of the prayer-book in public 'or in any private place or family' punishable by a fine of £5 for the first offence, £10 for the second, and a year's imprisonment for the third. This harsh measure went a long way to provoke the reaction of the Act of Uniformity (1662).

On the restoration of the monarchy, in the vain hope of satisfying contending ecclesiastical parties a royal commission was issued (March 25, 1661) to twelve bishops and twelve Presbyterian divines (with nine coadjutors on each side to fill the places of members of the commission who might be absent) 'to advise upon and review the Book of Common Prayer, comparing the same with the most ancient liturgies which have been used in the church in the primitive and present times . . . and, if occasion be, to make such reasonable and necessary alterations, corrections, and amendments as shall be agreed upon for the giving satisfaction to tender consciences,' &c.

The meetings of the commission were held in the Savoy Palace in the Strand, London, and hence the name the 'Savoy Conference,' by which they are commonly designated. Among the best known of the divines of the Episcopal side were Bishops Cosin, Sanderson, and Brian Walton, with Drs Pearson, Gunning, and Heylin. Among the Presbyterians the most eminent were Baxter, Calamy, Bates, Manton, and Reynolds. One of the most notable episodes in the history of the conference was the presentation by Baxter of a liturgy, composed by himself in the space of a few days, which the Presbyterian commissioners desired should be authorised and placed on a footing of equality with the Book of Common Prayer. The conference, as was to be expected from the temper of the times, ended in the discomfiture of the Puritan party, very few of whose suggestions were adopted. Subsequently royal letters were addressed to Convocation directing the revision of the Book of Common Prayer. This revision brought the book to its present state, with the exception of changes in the lectionary, to be noticed below. The result of the revision was authorised by the Convocations of Canterbury and York, and its use enjoined (19th May 1662) by parliament (Act of Uniformity, 14 Carol. II. chap. 4).

Among the more noteworthy changes made at the last revision may be mentioned a new preface (by Bishop Sanderson); the adoption of the Authorised Version for the Epistles and Gospels, the introduction of the prayer for parliament, of the prayer 'for all conditions of men,' of the general thanksgiving, and some of the special thanksgivings: and the reintroduction in a modified form of the commemoration of the departed in the communion service. While the general framework of the prayer-book was preserved intact, very many minute changes were made, more particularly in the rubrics. Speaking generally, the changes, when they possess any distinctive doctrinal colouring, were marked by the dominant influence of the church party. Two entirely new services were added: (1) a service for the baptism of adults, made desirable by the growth of anabaptism during the Great Rebellion, as well as by the need of a form for the baptism of the heathen in our 'plantations;' and (2) a form of prayer and thanksgiving to be used at sea, with a special view to 'his majesty's navy.' Certain printed copies of this prayer-book, minutely examined and brought into conformity with the MS. copy attached to the act of parliament, were certified as correct, and having the great seal attached to them are known as the *Sealed Books*. One of these sealed copies was deposited in the Tower of London, one in each of the Courts of Law at Westminster, and one with each cathedral chapter.

In the reign of William III. an attempt was made to further revise the prayer-book with a view to the comprehension of dissenters. A royal commission sat and reported, but nothing came of it. In 1872 the table of lessons now in use was approved by convocation, and authorised by parliament (34 and 35 Vict. chap. 37). In the following year certain abbreviations in the daily service were similarly sanctioned (35 and 36 Vict. chap. 35).

In Ireland it may be noted that the first book ever printed in Dublin was the First Prayer-book of Edward VI. It appeared in 1551. The Second Prayer-book of Edward was never introduced. Elizabeth's prayer-book was enjoined by the Irish parliament in 1560, and similarly in 1662 the prayer-book as revised after the Savoy Conference. On the disestablishment of the Irish Church (1869) a revision of the prayer-book was carried through by the General Synod, after a contest between church parties extending over several years. In 1878 the revised prayer-book was published. Among the more important changes are (1) the removal of the rubric preceding the Athanasian Creed; (2) the addition of a question and answer to the Catechism declaring that the body and blood of Christ are 'taken and received only after a heavenly and spiritual manner;' (3) the absolution in the visitation of the sick changed into the form in the communion service; (4) lessons from the Apocrypha removed.

In the Episcopal Church of the United States of America a revised edition of the English prayer-book was authorised and published in 1789. The changes made were very numerous. We can here specify only the following: (1) the removal of the Athanasian Creed; (2) the introduction of the 'invocation' on the elements in the communion service, this latter being at the suggestion of Seabury, the first American bishop. He had been consecrated in Scotland, and was warmly attached to the Scottish Communion Office, of which the 'invocation' is a characteristic feature. A further revision was undertaken in 1881. So far as it has hitherto proceeded, it is largely marked by a desire to revert to particulars of the English prayer-book which had been abandoned in 1789; but neither of the two features noticed above has been altered.

In the Episcopal Church in Scotland the English prayer-book is formally declared to be the 'duly authorised service-book of this church for all the purposes to which it is applicable' (Canon xxxiii.); but a service for the Holy Communion (brought to the form in current use in 1764) is sanctioned in some congregations under certain restrictions. At

all consecrations, ordinations, and synods the form in the English prayer-book is required to be used. The Scottish Communion Office is based on the corresponding service in Laud's prayer-book, but many important changes have been made. Among the most noteworthy are (1) the transposition of the place of the prayer of consecration in relation to the prayer for 'the whole state of Christ's Church;' (2) the omission of the words 'militant here in earth;' (3) the alteration in the order of the parts of the prayer of consecration, so that it runs, (*a*) words of institution, (*b*) oblation, (*c*) invocation; (4) the substitution, in the invocation, of the words, 'that they may become the body and blood,' &c., for 'that they may be unto us the body,' &c. This last change is for its abruptness without parallel or precedent.

For the materials from which the prayer-book has been mainly constructed, consult Maskell's *Monumenta Ritualia Ecclesiæ Anglicanæ* (2d ed. 1882), and *The Ancient Liturgy of the Church of England* (3d ed. 1882); *Missale ad usum Sarum* (Burntisland ed. 1861–67); *Breviarium ad usum Sarum*, edited by F. Procter and C. Wordsworth (1879–86); *Breviarium Romanum Quignonianum*, edited by J. W. Legg (1888). The successive changes made in the English Prayer-book and the Scottish Prayer-book (1637) are admirably exhibited in parallel columns in Keeling's *Liturgiæ Britannicæ* (2d ed. 1851); they may also be studied in J. Parker's *The First Prayer-book of Edward VI., compared with the successive Revisions of the Book of Common Prayer* (1877). For the history of the prayer-book and a commentary on its contents, see Procter's *History of the Book of Common Prayer, with a Rationale of its Offices* (18th ed. 1889); J. H. Blunt's *Annotated Book of Common Prayer* (revised ed. 1884); Cardwell's *History of Conferences . . . connected with the Revision of the Book of Common Prayer* (2d ed. 1841). Parker's *Introduction to the History of the successive Revisions of the Book of Common Prayer* (1877) is invaluable. Cranmer's attempts at a revision of the Breviary is exhibited in *Edward VI. and the Book of Common Prayer* (1890), by F. A. Gasquet and E. Bishop. Much curious information on the mediæval liturgies of England, more particularly that of York, will be found in the *Lay Folk's Mass Book*, edited for the Early English Text Society by T. F. Simmons (1879). Among commentaries on particular parts of the prayer-book, Scudamore's *Notitia Eucharistica* (2d ed. 1876) and Bulley's *Variations in the Communion and Baptismal Offices* (1842) are of much value. The *Facsimile of the original Manuscript of the Book of Common Prayer attached to the Act of Uniformity, 1662*, was produced in photo-lithograph in 1890. On the history of the Scottish and American Communion Offices, see the writer's *Annotated Scottish Communion Office, &c.* (1884), and the *Historical Sketch* appended to Professor S. Hart's edition of *Seabury's Communion Office* (1874).

Prayer Beads, a name given to the polished seeds of a West Indian leguminous plant, *Abrus precatorius* or Wild Liquorice, formerly much used for stringing into rosaries, necklaces, &c.

Praying Wheel, an instrument for offering prayers by mechanical means, used exclusively by the Lamaist Buddhists, on the assumption that the efficacy of prayer consists in the multiplicity of its repetition. These instruments are of various shapes and sizes, from small cylinders turned by the hand to huge ones driven by water or wind. Long strips of paper with a written or printed formula, which translated reads 'The Jewel in the Lotus, Amen,' repeated hundreds or even thousands of times, are wrapped round these cylinders, and as the cylinders revolve the paper rolls uncoil, and so the prayer is said.

Preaching, or systematic instruction in religion given by word of month, has been almost from the beginning of the Christian church the principal means of disseminating its doctrines, and already its application to the poor is given by our Lord himself as one of the significant signs of the new economy. It is thus distinctively Christian, although it is true that it traces its ancestry to part of the function of the ancient Israelitish prophets, who were instructors of the people as to their duties in the present, as well as foretellers of the future. The teaching of Christ himself, so far as recorded, mostly took the form of the parable, and throughout we find its characteristic marks to be simplicity and variety, some common fact in nature or human experience being taken as the basis of the sermon, and spiritualised in a free and natural manner. But, as Vinet says, Jesus himself instituted little, though he inspired much. The discourses given in the Acts also differ widely from modern sermons, their main object being to bring the person and history of Christ plainly before their hearers. The facts of His life, death, and resurrection are everywhere put forward as the roots of Christian faith and practice, and doctrine is ever interpreted without complexity, as practically connected with His person. Justin Martyr (*Ap. maj.* chap. 67) and Tertullian (*Apol.* chap. 39) describe the exhortations that followed the reading of Scripture in their time; but Origen was the earliest preacher in the modern sense of the word, although he employed largely the allegorical method of interpreting Scripture, happily now almost extinct. In the early church the bishop was long responsible for the preaching, although presbyters and deacons came to be employed, as Origen was before his ordination, and Constantine frequently. Monks were not allowed to preach until the special preaching-orders were organised in the middle ages, nor yet women, although the Montanist heretics permitted them. Sermons were usually delivered on Sundays, as part of the regular religious service, and approbation was expressed by stamping of feet and clapping of hands, a practice which Chrysostom condemned. After the 9th century preaching appears to have declined, and indeed it never seems to have flourished much at Rome. The mediæval sermon gradually took the form of a short address after mass; but, with the rise of the Franciscan and Dominican orders, we find a great revival of preaching, in form popular, racy, the anecdotes told and spiritualised perforce (*Exempla*) often anything but edifying in themselves. Among the most famous of the mediæval preachers were Antony of Padua, Bernard of Clairvaux, Bonaventura, Berthold the Franciscan of Regensburg, John of Monte Corvino, Savonarola, John Tauler of Strasburg, and Francis Coster (1531–1619). The Reformers were preachers to a man, and the swift progress of the new doctrines was in great measure due to the power with which they were given forth from the pulpit. As sacramentarianism lost hold of men's consciences, the higher appeared the value of the new method of learning by what means to draw near to God. Wyclif and his Poor Priests, and after him the Lollards, established an evangelical tradition of the supremacy of the pulpit as a means of grace, which we find at its greatest strength in Puritanism. Seventeenth-century preaching was very scriptural, and put prominent in the foreground the cardinal evangelical facts of the fall of man, the doom of sin, the redemption of Christ, the sanctifying work of the Holy Spirit. Its strength lay in the reality and vigour with which it realised these truths; its weakness was a tendency to be over-abstract, and to become theological rather than religious. In the unspiritual barrenness of the 18th century preaching became mainly ethical and apologetic—preaching about Christianity rather than preaching Christ; but, as Dr Johnson says, men at last got tired of hearing the apostles tried once a week for the crime of forgery, and turned for relief to listen to the earnest direct harangues of a Wesley and a Whitefield.

The whole century could show no preachers to be compared with Latimer, Donne, Hall, Andrewes, Jeremy Taylor, Howe, Baxter, as well as Fuller, Sanderson, South, Barrow, and Tillotson: still less with their magnificently eloquent French contemporaries Saurin, Bourdalone, Bossuet, Fénelon, Massillon, La Rue, and Fléchier. But in the 19th century the pulpit recovered all its power, despite a stock platitude of the modern press to the contrary, with such an illustrious roll of preachers as Chalmers, Edward Irving, Robert Hall, F. W. Robertson, Henry Melville, Maurice, Hook, Newman, Mozley, Wilberforce, Martineau, Archer Butler, Arnold, Spurgeon, Caird, Guthrie, Beecher, Talmage, Moody, Magee, Liddon, Knox Little, Farrar, Maclaren, Parker, and Philips Brooks. In France again we find the names of Lacordaire, Monod, Bersier, and Pressensé; in Germany the Reformation preaching has been choked by Rationalism, but within the century reached its finest flower in Schleiermacher, in whose sympathetic heart there met in strange harmony Pietistic and Rationalist traditions alike. Spener the Pietist, Zollikofer, and Reinhard were earlier German preachers of high rank.

The modern Church of England has been driven, through the activity of its dissenting rivals, to recognise its neglect of preaching by opening the naves of its cathedrals for special evening services, and now actively employs the pulpit in every parish as a principal engine of its warfare against evil, still recognising it, however, in the words of Dr Hook, as 'a means of instruction, more than a direct means of grace.'

The chief difficulties of the preacher are that he has to speak always to the same hearers—Wesley said even in a year he would preach both them and himself asleep; his audience is of very varying degrees of education and intelligence; his theme is so familiar that it is difficult to compass the grace of novelty—indeed the wonder is rather, as Borrow said, that so many are so good as they are, seeing that the demand in the British Isles alone extends to about 100,000 sermons a week. The foundations of the preacher's success may be said to be his personality, his sincerity, piety, and enthusiasm, his respect and love for his hearers, knowledge of their conditions of life, wider knowledge of human nature and experience of the world, together with gravity, courage, and intellectual and moral honesty. If to these be added exegetical learning, natural eloquence and fire, with the power of forgetting self in the message to be delivered as an ambassador for Christ, and finally unction—which, as Vinet says, there is no artificial means of gaining—a preacher of the very highest order is formed. The greatest snare to the young preacher is a not unnatural self-consciousness, and still more the assumption of affectations of voice or action, from which he would quickly shake himself free if he could see how really ridiculous he appears to the pews. The best tonic for his self-consciousness is to be reminded that he himself is but an accident in the vast Christian scheme for the propagation of the gospel, and that the greatest of the apostles was himself content to be nothing so Christ was preached. Happily men without some approximation to a vocation now choose the clerical profession less frequently than formerly, for it is more difficult now to be a Charles Honeyman than it was in our great satirist's days. The sovereign law of preaching is to be genuine and natural, for, as Faust says, 'no heart will take fire if the spark does not come first from the speaker's heart.' In nothing is this bane of unreality to be more guarded against than in the pulpit tone —the high falsetto, the impressive roll, the insinuating whisper, or even whine, are one and all to be abhorred, as suggesting to the ear merely simulated emotions. The best method is to begin from a conversational level, to employ a completely unaffected language and style, and to aim throughout at clearness, all unfair use of the text and unauthorised spiritualising being inadmissible. Plain sensible thoughts in sensible English will always be listened to with patience, if not too long, for the modern hearer endures with difficulty more than thirty to forty minutes, where his fathers expected something at least twice as long. The judicious preacher will seasonably lighten his discourse with illustrations, terse proverbs, and anecdotes, for, as Fuller says, 'while reasons are the pillars, similes are the windows of every structure.' The same over-witty old divine adds a caution which it can scarcely be said he himself never forgot, 'The preacher avoids such stories whose mention may suggest bad thoughts to the auditors, and will not use a *light* comparison to make thereof a grave application, for fear his *poison* go farther than his antidote.' But, while avoiding the grotesque, the preacher must not forget Quintilian's fatal judgment of mediocrity—'his excellence was that he had no fault, and his fault that he had no excellence.' Jeremy Taylor was a master in the art of illustration, some of his examples being among the most exquisite passages in English prose. The preacher may find his inspiration in the legitimate use of the sermons and other writings of others, no less than in his own experience of life. Even so original a man as Robertson of Brighton says, 'I cannot copy, nor can I work out a seed of thought, developing it myself. I cannot light my own fire; but whenever I get my fire lighted from another life I can carry the living flame as my own into other subjects, which have been illuminated in the flame.' Even the preacher's old sermons are full of advantage to him, if judiciously employed to enrich, rather than merely fill out, the new. For is it not true that 'the good parishioner inquireth not whether the sermon be new or old, but, like good venison, if it be savoury, falls to to profit by it?' There is an honest use that may be made of the thoughts of others and even of one's self, when these are vivified anew by the judgment and thought of the present occasion. Rank plagiarism is entirely to be reprobated, but there is an honest middle course which will not vex the conscience of the preacher himself, nor exercise the most careful listener. What is taken from all books is borrowed from none, and the preacher may do with sermons what Dr Johnson tells us Watts did with materials gathered from a wider range—'every kind of information was, by the piety of his mind, converted into theology.'

The early preachers, as Chrysostom and Augustine, spoke extempore, and indeed the practice of reading sermons from a manuscript does not seem to have been practised before the Reformation, when Burnet tells us the book of Homilies was compiled on account of the fewness of qualified preachers and the urgent necessity to get the people instructed. Still, reading long remained unpopular, and 'the present supine and slothful way of preaching' was actually forbidden by statute to the university preachers at Cambridge in 1674. Leighton disliked it as detracting from the weight and authority of preaching—'I know,' he says, 'that weakness of the memory is pleaded in excuse for this custom; but better minds would make better memories. Such an excuse is unworthy of a father addressing his children. Like Elihu, he should be refreshed by speaking.' Reading gained ground in the 18th century, and sermons were bought, borrowed, or stolen by preachers less honest than Sir Roger de Coverley's chaplain. The advantage of reading is that it usually ensures a

better ordered discourse and saves the preacher from what to many is a grievous slavery; but Dr James Martineau puts its defence on yet higher grounds as the best means of maintaining the high level of thought and feeling at which the sermon was composed. And it is true that many, perhaps most, extempore preachers forget their argument, and never progress, but eddy round and round, as Coleridge said, in verbiage, vain repetitions, and feeble and garrulous fluency. But against this there is the obvious disadvantage in the loss of power and reality that must needs follow the rewarming of premeditated emotion. The recitation of sermons by heart is scarcely better, if not indeed still more likely to destroy spontaneity and naturalness of expression, not to speak of the risk of some accident depriving the helpless reciter of his memory, as once happened to South, whereupon he left the pulpit abruptly with the words, 'Lord be merciful to our infirmities.' The method of extempore preaching is in every respect the best, provided the speaker's standard of excellence is one sufficiently high, and he is not one of those vain men who make a boast of going into the pulpit without premeditation. Provided the sermon has been carefully thought out beforehand, and the preacher has some measure of faculty in speech, this method of preaching will be found the most effective, the thoughts being previously methodised, the words and sentences left to the moment. For it is both the most natural manner and it allows speaker and hearers alike to be lifted simultaneously on the same waves of thought and emotion. For, unhappily, there are few men capable of reading a sermon with the same fire and glow as Chalmers. But the speaker must be cool and self-possessed—'a great deal of talent is lost to the world for want of a little courage,' says Sydney Smith—and this quality he must possess in a quite unusual degree if he essays the task of preaching to crowds in the open air. The great French preachers, again, recited their sermons, apparently finding it easier than Englishmen do to revive premeditated emotion. Massillon said that his best sermon was the one he knew best; Bourdalone, whose memory was apt to give way in presence of any distraction, used to preach with his eyes closed.

'Most men,' said Leighton, 'begin to preach too soon, and leave off too late;' and still worse for the quality of the sermon is the too frequent necessity for the production of two or more every week. Bishop Andrewes said, 'He who preaches twice will prate once;' and Robert Hall used to say, 'A man who concentrates his ideas, and thinks out his subject properly, can write one; a diffuse, shallow man may manage two, and a fool might very likely write half a dozen.' Those under the necessity of producing two might well be permitted to make the second a diet of catechising, as Hooker did at Bishopsbourne; or an address specially directed to children—an admirable new feature of modern preaching; or the second might be frankly allowed to be taken from some great divine, or at least to be merely one of those simpler extemporaneous sermons Hooker describes, 'which spend their life in their birth, and may have public audience but once.' Over-tasked preachers will find help in those collections of skeleton sermons, of which Simeon's *Horæ Homileticæ* (21 vols. 1783–1836) and Spurgeon's *Sermon Notes* (4 vols. 1884–88) are well-known examples.

As for the form of the sermon, it is usual for it to be divided into an *introduction* or exordium, the *proposition*, the *proof*, and finally the *conclusion* or peroration. Simeon and his school announced the divisions at the outset; Newman notices them only as he passes from one to the other. As for the logical divisions or *heads*, in which the Puritan preachers were so prolific—Baxter once having as many as 120—the more modern usage is to emphasise these but lightly and to have as few as possible. These are of course all important in the structure of the sermon, for, as Quintilian says, 'Qui rectè diviserit, nunquam poterit in rerum ordine errare.' George Herbert, in *The Country Parson*, warns against 'crumbling a text up into small parts;' and Bishop Leighton introduced into Scotland the method of preaching without heads—'skimming the text,' as it seemed to the zealots of his day. The introduction should be of the shortest, and may take the form of an exegetical connection of text with context—as in Liddon almost always, or an analogy, or an anecdote. The proposition should be clearly set forth, and the proof should follow in logical order, although the heads need not be named. The conclusion, peroration, or application should be an earnest, pointed appeal, warranted by the arguments that have preceded it. 'Hic, si unquam, totos eloquentiæ fontes aperire fas est,' says Quintilian. Indeed, fire and passion we cannot have too much of, if only it is justified by masculine feeling, keeping pace with the march of the argument, yet allowing the speaker to become the clearer the more he glows. Hume said John Brown of Haddington preached as if Jesus Christ was at his elbow, and James Melville tells us that Knox ere he had done with his sermon 'was like to ding the pulpit in blads, and fly out of it.' Or if a tender closing appeal best fits the subject the speaker must remember that he is a man and not allow himself to be dissolved in tears, unless he needs must, when nature will save him from being ridiculous. Bishop Heber converted the closing words of his sermon into a prayer.

In the expository discourse, technically known in Scotland as 'a lecture,' the preacher takes a series of texts or a whole passage, and opens up its meaning, the central truth being clearly set forth, and the minor truths in their relation to it.

Many of the older preachers of the evangelical persuasion never closed a single sermon without a hasty course round the whole range of cardinal doctrines in the scheme of salvation, however wide some of these might lie from the subject proper of the text. This might be well for itinerating preachers like Whitefield and Wesley, who would most probably never address the same hearers again; but is manifestly absurd in the case of a parish clergyman whose duty is to instruct the saints as well as rouse the unconverted, and who speaks to the same people twice a week. Those preachers whose sermons invariably deal with the initiatory stages of Christian experience sometimes arrogantly claim for themselves a monopoly of 'preaching Christ.' No phrase has been more abused than this of St Paul's, which has been twisted to mean a monotonous iteration of the necessary conditions of the starting-point only of a Christian experience, as if the pupils of a school were to stand still at their primer because one had not yet learned to spell. But indeed there is too little variety in our teaching—'We hold a few texts,' says Archer Butler, 'so near our eyes that they hide the rest of the Bible.' Still less profitable were those weekly tirades against the Socinians, the Scarlet Woman, or Prelacy, forced into the conclusion of every sermon by many a painful old Presbyterian divine. Even hell lost its terrors when made a weekly show, and the majestic personality of the devil, once familiar, became contemptible. But the pains of hell have furnished the fuel for many a noble sermon, even without such a special accessory as Fuller tells us belonged to Mr Perkins, who 'would pronounce the word *damn* with such an emphasis as left a doleful echo in his

auditors' ears for a good while after.' The autobiographical style is a persistent snare to young converts in their preaching, forgetting how diverse are human character and conditions, how complex is Christian experience, and how large and varied was Christ's own conception of the kingdom of heaven. The most alarming danger to the pulpit in the present day is, however, a maudlin hysterical style of treating religious truths, natural enough in a society debauched with the over-excitement and fever of an age of competition, but ultimately fatal to the dignity and authority of a venerable institution, the real foundations of which must be mastery over emotion and firmness of intellectual fibre, as well as comprehensive grasp of the truths revealed by Jesus Christ.

See Dr J. M. Neale, *Mediæval Preachers and Preaching* (1857); Rev. S. Baring-Gould, *Post-mediæval Preachers* (1865); Rothe, *Geschichte d. Predigt vom Anfang bis auf Schleiermacher* (Bremen, 1881); the Rev. G. J. Davies, *Papers on Preaching* (3d ed. 1883); Professor Mahaffy, *Decay of Modern Preaching* (1882); Professor John Ker's fragmentary *Lectures* (1887); the treatises on Homiletics by Vinet (1858), Kidder (1864), Hoppin (1869), and Blaikie (1873); also the excellent series of Yale lectures by Beecher, Philips Brooks, Dale, and others.

Pre-Adamites. See ADAM.

Prebend. See CATHEDRAL.

Precedence, the order in which individuals are entitled to follow one another in a state procession or on other public occasions. In England the order of precedence depends partly on the statute of 1539, partly on subsequent statutes, royal letters-patent, and ancient usages. Among questions of precedence depending on usage there are some which can hardly be considered so settled as to be matter of right, and are in a great degree left to the discretion of the crown, which generally refers any disputed question to the officers of arms. In Scotland the Lyon Court has the direct jurisdiction in all questions of precedence.

It is a general rule of precedence that persons of the same rank follow according to the order of the creation of that rank; and in the precedence of the English peerage it has been fixed that the younger sons of each preceding rank take place immediately after the eldest son of the next succeeding rank. Married women and widows take the same rank among each other as their husbands, except such rank be professional or official, and it is an invariable rule that no office gives rank to the wife or children of the holder of it. Unmarried women take the same rank with their eldest brother; the wife of the eldest son, of any degree, however, preceding the sisters of her husband and all other ladies in the same degree with them. Marriage with an inferior does not take away the precedence which a woman enjoys by birth or creation; with this exception, that the wife of a peer always takes her rank from her husband. The following tables exhibit the precedence of different ranks as recognised by law in England.

TABLE OF PRECEDENCE AMONG MEN.

The Sovereign.
The Prince of Wales.
Sons of the Sovereign.
Grandsons of the Sovereign.
Brothers of the Sovereign.
Uncles of the Sovereign.
The Sovereign's brothers' or sisters' sons.
Archbishop of Canterbury, Primate of all England.
Lord High Chancellor, or Lord Keeper, being a Baron.
Archbishop of York, Primate of England.
Lord High Treasurer.
Lord President of the Privy-council. } Being of the degree of Barons.
Lord Privy Seal. }
Lord Great Chamberlain. }
Lord High Constable.
Earl Marshal. } Above all of their degree; if Dukes, above all Dukes, &c.
Lord High Admiral. }
Lord Steward of H.M. Household. }
Lord Chamberlain of H.M. Household. }
Dukes.
Eldest sons of Dukes of the Blood Royal.
Marquises.
Dukes' eldest sons.
Earls.
Younger sons of Royal Dukes.
Marquises' eldest sons.
Dukes' younger sons.
Viscounts.
Earls' eldest sons.
Marquises' younger sons.
Bishops of London, Durham, and Winchester.
All other English Bishops according to seniority of Consecration.
Secretaries of State, if Barons.
Barons.
Speaker of the House of Commons.
Commissioners of the Great Seal.
Treasurer of H.M. Household.
Comptroller of H.M. Household.
Master of the Horse.
Vice-chamberlain of H.M. Household.
Secretaries of State, under degree of Baron.
Viscounts' eldest sons.
Earls' younger sons.
Barons' eldest sons.
Knights of the Garter.
Privy-councillors.
Chancellor of the Order of the Garter.
Chancellor of the Exchequer.
Chancellor of the Duchy of Lancaster.
Lord Chief-justice.
Master of the Rolls.
Lords Justices of Appeal.
Judges of the High Court of Justice.
Bannerets made by the Sovereign under the royal standard in open war.
Viscounts' younger sons.
Barons' younger sons.
Baronets.
Bannerets not made by the Sovereign in person.
Knights Grand Crosses of the Bath.
K. Grand Commanders of Star of India.
K. Grand Crosses of St Michael and St George.
K. Grand Commanders of Order of Indian Empire.
Knights Commanders of the Bath.
Knights Commanders of the Star of India.
K. Commanders of Michael and George.
Knights Bachelors.
Judges of County Courts.
Companions of the Bath.
Companions of the Star of India.
Cavalieri and Companions of Michael and George.
Companions of Order of Indian Empire.
Companions of the Distinguished Service Order.
Eldest sons of the younger sons of Peers.
Baronets' eldest sons.
Eldest sons of Knights of the Garter.
Bannerets' eldest sons.
Eldest sons of Knights, according to their fathers' precedence.
Eldest sons of Knights Bachelors.
Baronets' younger sons.
Knights' younger sons.
Esquires.
Gentlemen.

TABLE OF PRECEDENCE AMONG WOMEN.

The Queen.
The Princess of Wales.
Princesses, daughters of the Sovereign.
Princesses and Duchesses, wives of the Sovereign's sons.
Granddaughters of the Sovereign.
Wives of the Sovereign's grandsons.
The Sovereign's sisters.
Wives of the Sovereign's brothers.
The Sovereign's aunts.
Wives of the Sovereign's uncles.
The Sovereign's nieces.
Duchesses.
Wives of eldest sons of Royal Dukes.
Daughters of Dukes of the Blood Royal.
Marchionesses.
Wives of the eldest sons of Dukes.
Daughters of Dukes.
Countesses.
Wives of younger sons of Royal Dukes.
Wives of the eldest sons of Marquises.
Daughters of Marquises.
Wives of the younger sons of Dukes.
Viscountesses.
Wives of the eldest sons of Earls.
Daughters of Earls.
Wives of the younger sons of Marquises.
Baronesses.
Wives of the eldest sons of Viscounts.
Daughters of Viscounts.
Wives of the younger sons of Earls.
Wives of the eldest sons of Barons.
Daughters of Barons.
Maids of Honour.
Wives of Knights of the Garter.
Wives of Bannerets.
Wives of the younger sons of Viscounts.
Wives of the younger sons of Barons.
Wives of Baronets.
Wives of Knights Grand Crosses of the Order of the Bath.
Wives of K.G.C.S.I.
Wives of K.G.C. Michael and George.
Wives of K.G.C. Order of Indian Empire.
Wives of Knights Commanders of the Bath.
Wives of K.C.S.I.
Wives of K.C. Michael and George.
Wives of K.C. of Order of Indian Empire.
Wives of Knights Bachelors.
Wives of Companions of the Bath.
Wives of Companions of the Star of India.
Wives of Cavalieri and Companions of St Michael and St George.
Wives of Companions of the Order of the Indian Empire.
Wives of Companions of the Distinguished Service Order.
Wives of eldest sons of Peers' younger sons.
Daughters of the younger sons of Peers.
Wives of the eldest sons of Baronets.
Daughters of Baronets.
Wives of the eldest sons of Knights.
Daughters of Knights.
Wives of the younger sons of Baronets.
Wives of the younger sons of Knights.
Wives of Esquires and Gentlemen.

At the coronation of Charles I. the rule of precedency of the nobility of England was introduced in Scotland; and it was arranged that peers of England (or their sons, &c.), of a given degree, should within England take precedence of peers of Scotland of the same degree; and that in Scotland this precedence should be reversed. But by the acts of Union with Scotland and Ireland the precedence in any given degree of the peerage has been established as follows: (1) Peers of England; (2) Peers of Scotland; (3) Peers of Great Britain; (4) Peers of Ireland; (5) Peers of the United Kingdom, and Peers of Ireland created subsequently to the Irish Union. A similar order is understood to obtain in regard to baronets, though in Ireland it seems lately to have become the practice to allow all baronets to rank according to the respective dates of their patents.

The following is the table of precedence in Scotland, as recorded in the Lyon Office. It is founded partly on usage and partly on the statutes of 1623 and 1661.

The Sovereign.
Lord High Commissioner during sitting of General Assembly.
The Prince of Wales.
Younger sons of the Sovereign.
Grandsons of the Sovereign, including sons of daughters.
Brothers of the Sovereign.
Uncles of the Sovereign.
Nephews of the Sovereign, including sons of sisters.
Lord Provost of Edinburgh within the city.
Hereditary High Constable.
Master of the Household.
Lord Chancellor, or Lord Keeper, if Baron.
Dukes.
Eldest sons of Dukes of the Blood Royal.
Marquises.
Eldest sons of Dukes.
Earls.
Younger sons of Royal Dukes.
Eldest sons of Marquises.
Younger sons of Dukes.
Viscounts.
Eldest sons of Earls.
Younger sons of Marquises.
Barons.
Keeper of the Great Seal.
Keeper of the Privy Seal.
Eldest sons of Viscounts.
Younger sons of Earls.
Eldest sons of Barons.
Knights of the Garter.
Privy-councillors.
Lord Justice-general.
Lord Clerk-register.
Lord Advocate.
Lord Justice-clerk.
Lords of Session (by date of appointment).
Knights Bannerets.
Younger sons of Viscounts.
Younger sons of Barons.
Knights Marischal.
Baronets.
Knights of the Thistle.
Grand Cross of the Bath.
Grand Cross of the Star of India.
Grand Cross of St Michael and St George.
Knights Commanders of the Bath.
Knights Commanders of the Star of India.
Knights Commanders of St Michael and St George.
Lord Lyon King-of-Arms.
Ushers.
Knights Bachelors.
Companions of the Bath.
Companions of the Star of India.
Companions of St Michael and St George.
Eldest sons of younger sons of Peers.
Eldest sons of Bannerets.
Eldest sons of Knights of the Garter.
Eldest sons of Baronets.
Eldest sons of Knights.
Younger sons of Baronets.
Younger sons of Knights.
Dean of Faculty.
Solicitor-general.
Esquires, including Heralds.
Gentlemen, including Pursuivants-at-Arms.

It seems to be held in England that the precedence of Scottish officers of state, judges, &c., as recognised before the Union, does not now extend beyond Scotland. There are rules for precedence for the members of the different professions, recognised among themselves, but which give no general social precedence. No rank, for instance, in the army, however high in itself, entitles its holder to precedence. Doctors in the universities are ranked thus: (1) Divinity, (2) Law, (3) Medicine. Official rank may often place its possessor, upon occasion of public ceremonials, in a position far above others of higher dignity than himself, but this, of course, confers no rank in the general order of civil precedence; on the other hand, men of official rank, who have higher personal precedence, are placed according to the latter; the wives and children of all those who derive their places on the scale from official rank have no consequent privilege. One of the leading principles of the law of precedence is that it emanates solely from father or husband, and cannot be acquired through a female unless in the case of a peeress in her own right.

Precentor (sometimes *Cantor*), the officer who directs the singing in a cathedral or parish church. See CHOIR.

Preceptors, COLLEGE OF. See EDUCATION, Vol. IV. p. 219.

Preceptory, the name given to certain houses of the Knights Templars (q.v.), the superiors of which were called Knights Preceptor. Other houses of the order were called 'commanderies.'

Precession, the name given to a slow motion of the earth, under the action of the sun and moon, which causes the poles of the heavens (which must remain always vertically above the poles of the earth) to describe circles on the sphere of the heavens about the poles of the ecliptic as centres. As the places of stars on celestial charts are marked with reference to the celestial poles, this motion of these poles causes all such charts to become less and less accurate with the lapse of time. A correction for precession has therefore to be applied to such charts in order to find the true places of stars at any epoch other than that for which they are constructed. This motion of the earth also causes the Equinoxes (q.v.) to recede slowly along the ecliptic, so that the sun comes to them, in his annual course, a little *earlier* each year. Hence the name, '*Pre*cession of the Equinoxes.'

The physical cause of this motion is the attraction of the sun and moon for the protuberant part of the earth around the Equator (see EARTH). This causes the earth slowly to turn on itself, as a spinning top *gyrates* when its speed slackens before it falls. As this disturbing force on the earth is small relatively to its mass, this turning takes place at the mean rate of only 50″·1 per annum. It requires, therefore, 25,868 years for the equinoxes to describe a complete circle on the ecliptic. For a very interesting case of the effect of precession, see POLE-STAR. In actual observation the effects of precession are complicated with those of Nutation (q.v.) and of change of inclination of the ecliptic. The subject is pretty fully discussed in a popular manner in Herschel's *Treatise on Astronomy.* For the suggested influence of precession, along with the increased eccentricity of the earth's orbit, or great climatic changes on the earth, see PLEISTOCENE, p. 236.

Précieuses. See RAMBOUILLET.

Precious Stones. See STONES (PRECIOUS).

Precipitate Ointment is of two kinds, the *red* and the *white*. The former contains red oxide of mercury, the latter ammoniated mercury, or white precipitate. In both cases great care is necessary that the mercury preparations are in a very fine state of division, and are intimately mixed with the ointment base. Both ointments are highly stimulating, and are of service in cutaneous eruptions. The *red* ointment is also employed in chronic conjunctival ophthalmia.

Precipitation, in Chemistry, is an operation in which decomposition occurs in a fluid, either through the action of the air, or of a gas, or of a chemical agent in solution; and is accompanied by the deposition of a solid substance that was either previously held in solution or that has been formed by chemical action.

Precognition. See CRIMINAL LAW (SCOTS).

Predella (Ital.), the step or ledge sometimes seen at the back of an altar; also the frieze or band of pictures along the bottom of an altar-piece.

Predestination, the eternal decree of God, whereby 'the elect' are foreordained to salvation. The correlative decree, whereby others are held to be foreordained to perdition, is commonly distinguished by the other term—Reprobation. The theory of predestination had its origin in the attempts of theological system to define the relations of the human and the divine will, and to reconcile the phenomena of human freedom with the belief in divine omnipotence. God's absolute will is represented by it as determining the eternal destiny of man, not according to the foreknown character of those whose fate is so determined, but according to God's own mere choice. They who are thus foreordained to eternal life are led to believe and live by the 'irresistible grace' of the Holy Spirit. In human salvation, therefore, God's will is everything, man's nothing. The principal scripture passage is Rom. viii. 29, 30. It was in the discussions between Pelagius and Augustine that the predestinarian view of the divine 'decree' was first fully evolved; and since their time opinion in the church has run in two great currents —the one perpetuating the influence of Pelagius, who regarded that decree as subordinated to the divine foreknowledge of human character; the other that of Augustine, who maintained the absolutism of that decree, and its independence of all prior human conditions. Pelagius recognised a possibility of good in human nature; Augustine denied any such possibility apart from the influences of divine grace. The one held that the choice of salvation lay in man's will; the other that man's will had no active freedom or power of choice since the fall. In 529 the system of Augustine was established by the Council of Arausio (Orange) as the rule of orthodoxy in the Western Church; but the reaction against the strictly logical nature of his dogma has been perpetually manifested by representatives of the more humane, though perhaps less logical doctrine of Pelagius, in every period of the church. Gottschalk, a German monk of the 9th century, carried the doctrine to its most extreme development. The Thomists (see AQUINAS), as predestinarians, opposed the Scotists, though Thomists insisted that God willed the salvation of all and has provided the means. The reformers Luther, Zwingli, and Calvin were Augustinians, though the Lutheran doctrine as formulated by Melanchthon is plainly different from that of Calvin and the Reformed Church. Some Jesuits are Congruists or modified Thomists; others admit that predestination to grace, but deny that predestination to glory, is irrespective of merit. Jansenism was a revival of Augustinianism. Arminius and the Synod of Dort mark a new period of the controversy. With such opposite representatives as Laud and Hales, a large part of the Church of England 'bade John Calvin good-night.' The followers of Wesley and Whitefield differed on this great doctrine. Even the Presbyterian churches, or large sections of them, have modified their high predestinarian doctrine in at least the statement of it. The common Augustinian doctrine of the Calvinistic symbolical books is called 'infra-lapsarianism;' moderate Calvinists or 'sub-lapsarians' hold that the fall of man (*lapsus*) was foreseen but not decreed by God (thus trying to avoid ascribing to God the origin of sin); while extreme predestinarians or 'supra-lapsarians' affirm that God not only foresaw and permitted, but decreed the fall of man, overruling it for good. Jonathan Edwards (q.v.) is a modern representative of rigid Calvinism. Catholics hold that the question is one rather of metaphysics than of faith.

See the article WILL and works there quoted, and the articles on Augustine, Pelagius, Calvin, Jansen, &c.; the theological handbooks of dogmatics; Luthardt, *Vom Freien Willen* (1863); Forbes, *Predestination and Free-will* (1878); Canon Mozley, *Treatise on the Augustinian Doctrine of Predestination* (1878).

Predicables. This is a term in the scholastic logic connected with the scheme of classification. There were five designations employed in classifying objects on a systematic plan: *genus*, *species*, *difference* (differentia), *property* (proprium), and *accident* (accidens). The first two—Genus and Species—name the higher and lower classes of the things classified; a Genus comprehends several Species. The other three designations—Difference, Property, Accident—express the attributes that the classification turns upon. The Difference is what distinguishes one species from the other species of the same genus; as, for example, the peculiarities wherein the cat differs from the tiger, lion, and other species of the genus *felis*. The Property expresses a distinction that is not ultimate, but a consequence of some other peculiarity. Thus, 'the use of tools' is a property of man, and not a difference, for it flows from other assignable attributes of his bodily and mental organisation, or from the specific differences that characterise him. The Accident is something not bound up with the nature of the species, but chancing to be present in it. Thus, the high value of gold is an Accident; gold would be gold though it were plenty and cheap. See CATEGORIES, GENERALISATION.

Pre-emption. In the United States, under the Pre-emption Act of 1841, an actual settler on the public lands enjoys the right, in preference to any one else, of purchasing at a fixed price the land on which he has settled, to the extent of not more than 160 acres. In the case of 'offered' lands the settler must file his 'declaratory statement' within thirty days after entry, and within a year proof must be made of settlement and cultivation, and the land thereupon paid for, at $1·25 per acre if outside the limits of a railroad grant, or $2·50 if within such limits. If the tract settled on is 'unoffered,' an approved plan of the township must first be received at the district land office; the statement must then be filed within three months, and final proof and payment be made within thirty months thereafter. Title to land is thus obtained much sooner (possibly within six months) than under the homestead laws (see HOMESTEAD); but a homestead settler may at any time after six months purchase the land under the pre-emption laws; as, on the other hand, the holder of a pre-emption claim may convert it into a homestead.

Pre-established Harmony. See LEIBNITZ.

Pre-existence, DOCTRINE OF. The notion that human souls were in existence before the generation of the bodies with which they are united in this world was anciently, and is still, widely spread throughout the East. The Greek philosophers, too, especially those who held the doctrine of transmigration, as the Pythagoreans, Empedocles, and even Plato—if with him transmigration is not simply a symbolical myth—were familiar with the conception. Plato taught that all human souls had existed from the very beginning, still and silent, in the realm of potentiality, and Origen introduced the theory into Christian theology. The dogma of the assumption of the divine and human nature in Christ offers a grave difficulty in the relations between the two natures in pre-existence. Yet the belief continued to survive, and we find it in Scotus Erigena, in the

younger Fichte, in Glanvil and Henry More, and in one of the profoundest works of modern theology —Müller's *Christian Doctrine of Sin*—where it forms a basis for the doctrine of hereditary sin. Among the early Christians the assumption of such pre-existence was connected with the belief that God had created the souls of men before the world, and that these were united with human bodies at generation or at birth. Another view long prevalent in the Western Church was that of Traducianism, according to which children received soul as well as body from their parents through natural generation. The third theory, which ultimately became that of the orthodox, was Creationism, according to which each soul is created successively. Direct intellectual interest in the doctrine of pre-existence has nearly altogether ceased in modern times, yet the dream has again and again haunted individual thinkers. Almost every one is familiar in dreams, and even in a waking state, with a haunting sense of a want of reality in the common objects around, and a vague consciousness that everything one sees or hears has happened before, when we seem, in the words of Tennyson,

> To lapse far back in a confused dream
> To states of mystical similitude.

There is a striking expression of this experience in Sir Walter Scott's *Diary*, under February 17, 1828, and there is an interesting allusion to the same subject in a well-known passage in *Guy Mannering*. And Wordsworth has given supreme poetical expression to it in his famous ode—*Intimations of Immortality from Recollections of Early Childhood* (the germ of which will be found in a less known poem of Vaughan the Silurist):

> Our birth is but a sleep and a forgetting.
> The soul that rises with us—our life's star,
> Hath had elsewhere its setting,
> And cometh from afar,
> Not in entire forgetfulness,
> And not in utter nakedness,
> But trailing clouds of glory do we come
> From God, who is our home.

Prefect (Fr. *préfet*, from Lat. *præfectus;* see PRÆFECT), the administrative head of a modern French department (see FRANCE, Vol. IV. p. 775), whose duties correspond with those of the old *Intendant* before the Revolution.

Pregnancy. The first symptom which calls attention to the occurrence of pregnancy is usually absence of the menstrual flow. This may, of course, be suppressed by many other causes; and, exceptionally, may persist during the first few months of pregnancy. 'Quickening,' or the sensations experienced in consequence of the movements of the fœtus, is usually noticed in the fourth month. Of the changes which take place elsewhere than in the generative organs the first and most noticeable is sickness, usually occurring in the early morning, and not persisting beyond the first three months. 'Longings,' or cravings for special, and sometimes very curious articles of diet, are not unusual. The heart becomes enlarged in order to provide the increased blood-supply necessary for the nutrition of the fœtus. There is often an increased liability to toothache, fainting, and other disturbances of health; and not unfrequently the disposition is altered, and an unnatural fretfulness or irritability manifests itself. In some cases, on the other hand, the health is exceptionally good. The duration of pregnancy is, in the great majority of cases, about 275 days; but, as variations of a week or ten days in either direction are common, it is impossible to predict the exact date of delivery. Well-authenticated cases have occurred where it has been prolonged to nearly 300 days. It may, of course, come to an end at any time prior to its proper term (see FŒTUS). There is a curious condition called *spurious pregnancy*, which may so closely simulate true pregnancy in all its main features as entirely to deceive the patient as well as others. It is generally associated with Hysteria (q.v.) or some allied mental disturbance (see MARY I., and SOUTHCOTT). A careful examination enables a medical man to detect the mistake; but it may be difficult to persuade the patient and her friends of it. As a work of reference for others than specialists, Chavasse's *Advice to a Wife on the Management of her Health* (1842; new ed. 1889) may be recommended.

CONCEALMENT OF PREGNANCY is a criminal offence, or rather it is taken to be the main proof of the offence of concealing the birth of a child in certain circumstances. See BIRTH.

Prehnite, a hydrous silicate of alumina and lime, the alumina usually partly replaced by ferric oxide. It is a widely diffused mineral, and, although first discovered at the Cape of Good Hope, has been found in great beauty in some places on the continent of Europe and in Scotland. Prehnite exhibits a great variety of forms, being found in crystals in fan-shaped and cockscomb-like groups, granular, reniform, fibrous, &c. It is sometimes colourless, but more generally greenish, and sometimes yellowish. It occurs, as a product of the alteration of various silicates, in veins and cavities in crystalline igneous rocks, such as diorite, porphyrite, &c. Less commonly it is met with under similar conditions in granitoid and schistose rocks, and occasionally in lodes associated with copper.

Prejevalski, NICHOLAS, Russian traveller, was born in the government of Smolensk on 31st March 1839. He entered the army (1855), and took part in quelling the Polish insurrection of 1861. Having joined the general staff in 1867, he was moved to Siberia. There he began to satisfy his longing for travel by exploring the Usuri region, south of the Amur. This, however, was a small thing in comparison with his subsequent labours in geographical exploration. The three years 1871–73 he spent in travelling from Peking through southern Mongolia (region of the Ordus) to the Ala-shan, Koko-nor, and the upper waters of the Yang-tsze-Kiang. Four years later he made the first of the journeys undertaken with the hope of reaching Lhassa in Tibet, the goal of all his subsequent efforts. He rediscovered Lob-nor on the borders of East Turkestan and China, but failed three times in the same year to penetrate into Tibet. Two years afterwards he once more set out, and, after crossing the difficult highland region between East Turkestan and Tibet, had reached a point some 160 miles north of Lhassa, when the Tibetan authorities turned him back. He then went east, and explored the upper course of the Hoang-ho for about 200 miles, and finally reached Kiachta after a journey of nearly 15,000 miles. In the winter of 1883–84 he once more crossed the Desert of Gobi, and got as far as the upper Yang-tsze-Kiang, but, not being able to cross it or travel down it, was obliged to return. He died at Karakol, on the east side of Lake Issykkul in West Turkestan, just starting on his fifth expedition, on 1st November 1888. Prejevalski brought back from these journeys most valuable collections of animals and plants, now all preserved at St Petersburg; amongst other things that he discovered were the wild camel and the wild horse, the ancestors of the domesticated varieties. His accounts of his journeys were published in the *Proceedings* of the St Petersburg Geographical Society, in *Petermann's Mitteilungen*, and other journals, as well as in two independent Russian works (1875 and 1883). See *Nature*,

8th November 1888, and *Proc. Roy. Geog. Soc.*, 1879 *et seq.* The name also appears in the forms Prjevalski, Prchevalsky, and Prschevalsky.

Prelate (Lat. *prælatus*, 'one set over'), in Church law, is the name given to the holders of those higher dignities in the church, to which, of their own right, is attached a proper jurisdiction, not derived by delegation from any superior official. In this sense the name comprises not only prelates of the first class, as bishops, but also the heads of religious orders, abbots or priors of religious houses, and other similar ecclesiastical dignitaries. In the pope's court and household many of the officials, although not possessing episcopal or quasi-episcopal jurisdiction, have the insignia and title of prelate; and these honours are frequently bestowed on clergy whose duties keep them far from Rome.

Prelude (Lat. *præ*, 'before,' and *ludo*, 'I play'), the introductory movement of a musical work (see INTRODUCTION). The first movement of a suite was usually a prelude; and the term is especially associated with the pieces prefaced by Bach to his celebrated clavichord and organ fugues. It has also been applied, without special significance, by Chopin to his collection of short pieces, op. 28. Its form is indeterminate, but the piece is always in the same key as that succeeding it.

Premature Interment. See BURIAL.

Premature Labour. See ABORTION, FŒTUS, BIRTH.

Premier. See TREASURY, CABINET.

Pre-millenarians. See MILLENNIUM.

Premonstratensians (called also NORBERTINES), an order of regular canons, founded by St Norbert, a canon of Cleves, in 1119, at a place in the forest of Coucy, pointed out in a vision, and thence called Prémontré (Lat. *Pratum Monstratum*, 'the meadow pointed out'). Their habit was white, hence in England they were commonly called the White Canons. Norbert organised his new order, which was substantially a branch of the Canons Regular of St Augustine, as well with a view to the sanctification of the members as to their usefulness in effecting the reformation of the age. Himself a man of remarkable piety and austerity of life, his rule is a return to the primitive fervour of the monastic institute; and the great work which he proposed for his brotherhood, in addition to the daily choral services of the church, was the practical instruction of the people, and the direction of consciences in the confessional. It was taken up with ardour, and spread rapidly in France and the Low Countries, and afterwards—on Norbert's being chosen, in 1127, Archbishop of Magdeburg—in Germany; the abbot of the mother-house at Coucy, however, retaining the rank of general and of superior of the entire order. In 1512 all the abbeys in England and Wales were placed under the Abbot of Welbeck. There, just before the dissolution, were thirty-five houses; in Scotland there were six, one of them Dryburgh. It does not seem at any time to have made much progress, or at least to have established many houses, in Italy or Spain. In the same spirit of reformation Norbert established an order of nuns, which attained to equal success. Hélyot states that at one time there were as many as a thousand Premonstratensian abbeys, besides provostships and priories, and 500 houses of nuns, mostly in France, Germany, and the northern kingdoms. Lecuy, the last abbot of Prémontré, died so late as 1834. The abbeys were proscribed at the Revolution, and even in Germany, Belgium, and Austria there remain only miserable fragments of their former splendour. Small communities have been revived at Crowle and Spalding in Lincolnshire and at Storrington in Sussex.

Prentice Pillar. See ROSLIN.

Prenzlau, or PRENZLOW, an agricultural town of Prussia, stands at the northern end of Lake Ucker, 67 miles by rail NNE. of Berlin. It has a beautiful Gothic church (1325–40). Pop. (1895) 19,689.

Pre-Raphaelitism. English art of the 18th century had in its genesis one national peculiarity. There being no demand for it from church or state, it had to find its patrons (i.e. its means of existence) in the wants of the people. Hogarth, the first distinctly national subject-painter, found his themes in the social manners of his day, which were valued by the true instinct of the common people. Portrait-painters of national origin there had been before his time, but these, good and bad alike, had been followers of foreign masters introduced by the court and supported by its patronage. That art other than architecture was not necessarily an exotic in England is proved convincingly by the many beautiful examples of monumental portraiture produced by native workmen before the Wars of the Roses. The bronze effigies of Henry III. and Queen Eleanor in Westminster Abbey were executed by William Torel, citizen of London, in 1291–92, and those of Richard II. and Queen Anne of Bohemia by Nicholas Broker and Godfrey Prest, coppersmiths and citizens of London, in 1395–97. Austin of London furnishes an excellent and later example of this in his monumental tomb in the Beauchamp Chapel, Warwick. Those wars, followed as they were by the Reformation and in quick succession by the parliamentary troubles, smothered native art and necessitated the calling in of foreign aid; for it must be remembered that under the happiest conditions a native artist cannot be produced in less time than a full generation.

Hogarth having once arisen with full daylight of an independent inspiration, it was no longer possible for the mannered reproductions of the imitators of Kneller and Lely to satisfy the spirit of an age now awakened from its long sleep. Hogarth at first gained a footing by portraiture, and when later he devoted himself to subject-pictures he found a poor support by the sale of his engravings to the strictly middle classes. Amongst the wealthy there were two incentives to interest in art, one of these being found in ancestral dignity, the other in that love of sport so indelibly stamped upon English character. Sir Joshua Reynolds and Gainsborough arose, inspiring portraiture with their own precious grace and loveliness; animal-painters now well-nigh forgotten (such as Stubbs and his fellows) satisfied the latter; and Wilson as a landscape-painter made a heroic effort to graft upon the sportsman's instinct a larger love of nature. It has always been regarded as fortunate that at this time the reigning monarch, George III., declared his interest in the higher aims of art, an interest which expressed itself first in the establishment of the Royal Academy, and later in the patronage of Benjamin West for subjects of an exalted character. Although it is just that many of the works of this painter have since suffered a reversal of judgment, his picture of the 'Death of General Wolfe' will always remain a noble illustration of English history, largely justifying the king's favour. The great war for supremacy which at that time absorbed the nation's life, together with the almost ruinous debt then contracted, made further royal patronage impossible. It is easy now for any thoughtful person to trace how the high standard originally set was largely instrumental in sustaining the character of the art that followed. Its effects may be seen in the noble nature of the best works of Romney, Copley, Raeburn,

Opie, Girtin, Blake, Lawrence, Stothard, Constable, Wilkie, Haydon, De Wint, Crome, Turner, Leslie, and not less in the decorative designs of houses by the Adams brothers, in Wedgwood ware, in gold and silver work, and in furniture.

It is rarely that any cause for rejoicing may be found in the disastrous war of the beginning of the 19th century, but undeniably it did great things for the strengthening of English character, and this was the case in no direction more surely than in that of art. When in the peace of 1814 the Continent was thrown open, it is noted by three great painters, Haydon, Leslie, and Constable, that England stands supreme in painting among the nations, and this verdict was endorsed by the judgment of many able foreigners. The selection of Sir Thomas Lawrence to paint the members of the Holy Alliance is a convincing proof of this opinion, and the recognition of Constable by France in 1820 is further evidence to the same effect. But alongside of virtuous influences there had been at work a deadly academic dogma which the few far-seeing of that generation recognised as threatening destruction to the still struggling English school, an influence which had already completely destroyed decorative design. To glance at the members' lists of exhibitions of that day and to recognise how many then held great are now perfectly unknown, brings this to the proof. These painters were creatures of orthodox rule, line, and system, seeing whose influence Constable in 1821 prophesied 'in thirty years English art will cease to exist.' Following up this forecast of the great landscape-painter, Leslie thirty years later finds the fulfilment of Constable's prediction in the death of Turner.

It remained for the young generation to find out what lay at the root of the decay and also its remedy. How to get free from the prejudice which blinds the eye to established errors is the preliminary problem to effecting all reformation. The attempt made in Germany in the beginning of the century to cultivate what was called 'Early Christian Art,' was participated in by W. Dyce, D. Maclise, and a few other artists in England. But for youthful seekers after a perfect method these efforts, even where they expressed much of English individuality, were not unboundedly promising, because they lacked the full inspiration of nature. One of the earnest young students of the day was William Holman Hunt, who, already feeling his way as a practical painter, was led by circumstances to study in exceptional degree the works of the greatest old masters, and he perceived that in every school progress ended when the pupils derived their manner through dogmas evolved from artists' systems rather than from principles of design taught by nature herself. He determined therefore, for his own part, to disregard all the arbitrary rules in vogue in existing schools, and to seek his own road in art by that patient study of nature on which the great masters had founded their sweetness and strength of style. Without any idea of 'forming a school,' but for his own development alone, he began to study with exceptional care and frankness those features of nature which were generally slurred over as unworthy attention; and to this purpose he found most timely encouragement in the enthusiastic outburst of Ruskin's appeal to nature in all vital questions of art criticism, as expressed by him in *Modern Painters*.

At this period an increasing intimacy was cemented between W. Holman Hunt, aged nineteen, and John Everett Millais, who was already at the age of seventeen the precociously efficient medal student of the Royal Academy and an emulator of the pseudo-classical Etty. This youthful friendship led to frequent consultations over the needs of the growing generation of artists, and Millais declared his confidence in the closer study of nature, which he determined to adopt as soon as work to which he was committed should be completed.

Dante Gabriel Rossetti was at this time also fascinated by the newly-revived principle of patient striving after nature, but he had not yet become a practical painter, and there was no certainty that he would do so. He had, before his intimacy with Holman Hunt, begun the study of art under Ford Madox Brown, a painter who had distinguished himself by some of the most admirable contributions to the Westminster Hall competition, works which Rossetti had the independent good sense to admire. In the year 1848 (when Holman Hunt was engaged on a picture of Rienzi, of which he had already completed the painting of the landscape from nature, and other complicated preparatory work) D. G. Rossetti placed himself with Holman Hunt in his studio in Cleveland Street, where he followed a course of study specially devised for him by the older student to enable him to cope with the difficulties of a picture undertaken in pure experiment, in which finally he triumphed; this picture is now well known as 'The Girlhood of the Virgin.'

Millais, on his part, forthwith took for his first subject to be treated on the new principles a design from Keats's *Isabella*. This was originally intended for one of a series of etchings which the three, now formed into a band called the Pre-Raphaelite Brotherhood, had undertaken to publish. It is the justly famous picture now in the Liverpool Art Gallery.

The three artists, as representing the Pre-Raphaelite body, appeared in the exhibition season of 1849, Millais with 'Lorenzo and Isabella,' Holman Hunt with 'Rienzi,' Rossetti with 'The Girlhood of the Virgin,' and excited the most flattering attention; but by the following year a storm of enmity of the most bitter kind was raised against them. Their pictures this second year were 'Christian Priests Escaping from Druid Persecution,' by Holman Hunt; 'Christ in the House of his Parents,' by Millais; Rossetti's picture of the 'Annunciation' he exhibited (as he had done with his picture of the previous year) at another exhibition than the Academy. Many journals now joined the onslaught upon the three young artists, but undeniably the most damaging attack was one made by Charles Dickens in *Household Words*. (From this date to his life's end Rossetti discontinued public exhibition.) With this attack the bitter feeling against the young men so increased that in the following year (1851) one influential journal advocated that their pictures should be removed from the walls of the Royal Academy a few weeks after the opening of the exhibition. Thus, in the third year of its joint existence, the new school was threatened on all hands by powerful opponents, when there appeared in the *Times* three letters from Ruskin denouncing the spirit of jealousy and injustice with which the young men had been assailed. He pointed out the merits of the works and the great influence for good which the revival was likely to exercise upon the English school. Later followed a succession of pictures from the hands of the three young painters, works the titles of which have become familiar throughout England.

Among the works of Holman Hunt are 'Rienzi' (1849), 'Christian Priests Escaping from Druid Persecution' (1850), 'Two Gentlemen of Verona' (1851), 'Claudio and Isabella' (1853), 'Strayed Sheep' (1853), 'Light of the World' (1854), 'Scapegoat' (1856), 'Finding of Christ in the Temple' (1860), 'Isabella and the Pot of Basil' (1867), 'Christ the Carpenter' (1874). 'The Triumph of the Innocents' (1885). Amongst those of J. E. Millais are 'Isabella' (1849), 'Christ in the House of His Parents'

(1850), 'Ferdinand lured by Ariel' (1850), 'The Huguenot' (1852), 'Ophelia' (1852), 'The Order of Release' (1853), 'L'Enfant du Régiment' (1855), 'Vale of Rest' (1859), 'Autumn Leaves' (1865), 'Chill October' (1870), 'A Flood' (1870). Amongst those of D. G. Rossetti are 'The Girlhood of Mary Virgin' (1849), 'The Triptych. Llandaff Cathedral' (1856), 'Giotto painting the Portrait of Dante' (1859), 'Mary Magdalene at the Door of Simon the Pharisee' (1861), 'Beata Beatrix' (1865), 'The Blessed Damozel' (1877), 'La Donna della Finestra' (1879), 'The Day Dream' (1880), 'Dante's Dream' (1881), 'Found,' 'Proserpine' (1882). Many of these pictures exist in replica. For a list of Holman Hunt's collected works, see catalogue of Fine Art Society (1886); for J. E. Millais, Fine Art Society (1884), and Grosvenor Gallery (1886); for D. G. Rossetti, Royal Academy (1883).

Two of Rossetti's noble pictures have since his death become the property of the nation. These are the 'Annunciation' and 'Beata Beatrix.' Rossetti makes reference to many of his pictures in his sonnets. The title Pre-Raphaelite was adopted not without some sarcastic spirit intending to reflect upon the use of the name of the prince of painters by artists of the day to justify their own flimsy and un-Raphaelesque art; but it had also a more serious justification in the conviction that Raphael's latest style, having been adopted, as that of an emulator, from the system built up with slow effort by Michael Angelo and Leonardo da Vinci, did not at last altogether escape those marks of decadence entirely unknown in the works of his immediate forerunners. This defect the seekers after the second Renaissance traced to the remoteness of Raphael from those influences of the training of humility which the study of nature had directly or indirectly given in full measure to Michael Angelo and Leonardo da Vinci. The first pictures of the new school had upon them, together with the initials of the painters, the letters P.R.B., meaning Pre-Raphaelite Brotherhood; when public hostility became highly injurious (the meaning of the letters having been revealed, contrary to the original intention) this practice was abandoned.

Besides the three working founders, some few friends were enrolled as hopeful converts, with the idea that they would assist the movement. These were James Collinson and Thomas Woolner among artists, W. M. Rossetti, brother of the painter, and F. G. Stephens, who have followed other professions than art. There can now be little question that the Pre-Raphaelite school has exercised a powerful influence upon modern art; whether it has done so to the extent hoped for by its promoters lies with the future to reveal. One ambition which it had from the beginning was the restoration of decorative art; this has been much retarded by the hindrances of opposing forces; still, a great movement, clearly traceable to the revival, has taken place. There is no question that many established painters of the time were beneficially affected by the new impulse, but still more was this the case for the men who followed them. Unfortunately for the school, its recognition came too late for it to profit by the temporary patronage of art extended by government in the decoration of the Houses of Parliament, for which all the commissions were bestowed before the Pre-Raphaelite school could claim attention; their work, therefore, has been confined to the limits of private patronage, which for the poetic and ambitious art they aimed at is too limited a sphere. Works of national importance are the only entirely appropriate field for the highest efforts.

[In fulfilling the part of chronicler of Pre-Raphaelitism it has been inevitable that the writer should avow the degree of responsibility which he himself had in the movement, the more so, as statements of different tenor have appeared, and although the present article bearing the author's name may to some persons appear egotistical.—W. H. H.]

Prerogative, Royal. See Divine Right, Parliament, Sovereign, Pardon, Reprieve.

Prerogative Court, in England, was the court wherein all wills were proved and administrations taken out. It was so called because it belonged to the prerogative of the archbishop to take charge of these matters, which formerly fell under ecclesiastical superintendence. Hence there was a Prerogative Court for the province of Canterbury and another for the province of York. This jurisdiction was entirely taken away in 1858 from the ecclesiastics, and transferred to a new court called the Probate Court (q.v.).

Presburg (Ger. *Pressburg*, Hung. *Pozsony*), a town of Hungary, stands on the left bank of the Danube, 40 miles by rail E. by S. of Vienna and close to the Austrian frontier. It is backed by the spurs of the Little Carpathians, and is a pleasant town. Its principal buildings are the cathedral, a Gothic edifice of the 13th century (restored in the middle of the 19th), in which the kings of Hungary used to be crowned; the church of the Franciscans (1290–97); the town-house (1288), with a natural history collection; the parliament house, in which the Hungarian representatives used to meet until 1848; and some private houses. The royal castle (1645) was destroyed by fire in 1811, and is now a ruin. There is an academy of jurisprudence and philosophy. The chief objects of manufacture are beer, dynamite, wire, starch, spirits, confectionery, biscuits, &c.; and there is considerable trade in corn, sheep, cattle, swine, and wine. Pop. (1890) 52,411. Presburg grew to be a prominent town during the 11th and 12th centuries, and was frequently chosen for conferences and meetings between the rulers of Austria and Hungary. From 1541 (when the Turks seized Buda) down to 1784 it was the capital of Hungary. The town was taken by Bethlen Gabor in 1619, by the Austrians in 1621, and was bombarded by Davoût in 1809. Here on 26th December 1805 Napoleon concluded a treaty with the emperor after the battle of Austerlitz.

Presbyopia (Gr., 'old sight'), a change in the power of vision, not usually noticed till about forty-five years of age, when near objects come to be less distinctly seen than those at a distance. See Eye, Vol. IV. p. 512.

Presbyterianism. The name Presbyter is from the Greek *presbyteros*, 'elder.' The elders formed one division of the great council of the Jews, with the priests and scribes (Mark, xiv. 43); and every synagogue had its body of ruling elders (Luke, vii. 3, viii. 41). From these the name and some portion of the duties were transferred to the Christian church. We have no record of the first appointment of elders, but we find them as recognised rulers in the church of Jerusalem so early as the year 44 (Acts, xi. 30). The duties entrusted to them are these: (1) They had charge of the collections for the poor which were sent by the hands of Barnabas and Saul (Acts, xi. 30). (2) They are specially named as taking part in the council which was held at Jerusalem about the year 51 (Acts, xv. 2), and at the meeting of the church there when Paul reported his success among the Gentiles (Acts, xxi. 18). (3) They took part in the ordination of Timothy (1 Tim. iv. 14). (4) They were the pastors and bishops of the congregations. Thus the apostle Paul, addressing the elders of Ephesus, says, 'Take heed . . . to all the flock over which the Holy Ghost hath made you overseers (bishops) to feed the church of God' (Acts, xx. 28). And

writing to Timothy, he says, 'Let the elders that rule well be counted worthy of double honour, especially they who labour in word and doctrine' (1 Tim. v. 17). Elders also are found in all the churches. We have seen them in the mother-church of Jerusalem; and when Paul and Barnabas went forth on their first missionary journey, about the year 46, they ordained elders in every church (Acts, xiv. 23). Accordingly we find them in Ephesus about the year 60 (Acts, xx. 17), and in the same city a few years later (1 Tim. v. 17, with chap. i. 3), and in Crete. Titus is commanded 'to ordain elders in every city' (Tit. i. 5). These are the scripture facts on which the system of Presbyterianism as a government by elders is based. It does not recognise the bishop as the superior of the presbyter, for they were originally two names of the same persons. Thus in Titus, i. 5, 7, the apostle writes, 'Ordain elders in every city . . . for a bishop must be blameless,' and in Acts xx. those who in verse 17 are termed elders in verse 28 are termed bishops. On the original identity of the bishop and presbyter Bishop Lightfoot says, 'It is a fact now generally recognised by theologians of all shades of opinion, that in the language of the New Testament the same officer in the church is called indifferently bishop (*episcopos*) and presbyter.' There are two instances in which the term 'bishop' occurs apart from his being described as 'elder,' just as there are many examples of the elder being mentioned without his being termed bishop (Phil. i. 1; 1 Tim. iii. 2). In the writings of Clement of Rome, about the end of the 1st century, there is the same identity between the elder and the bishop; but from this period onwards the distinction between the two begins to appear, though Jerome in the 4th century writes: 'Among the ancients bishop and presbyter are the same, for the one is a term of dignity, the other of age.' See the articles BISHOP, CHURCH HISTORY, ORDERS (HOLY).

It used to be claimed that Presbyterianism survived in the ancient Celtic Church; but the Celtic polity, though differing widely from diocesan Episcopacy, was very unlike Presbyterianism (see IRELAND, p. 210; SCOTLAND, p. 242; COLUMBA; CULDEES). The Waldenses (q.v.) were perhaps anti-episcopal. But Presbyterianism as we know it first asserted itself at or after the Reformation, when earnest attempts were everywhere made to restore to the church primitive doctrine and form. In Germany, France, and the Continent, from the relationship of church and state, its free development was prevented (see CONSISTORY). It was Calvin (q.v.) in Geneva who, though not its originator, gave Presbyterianism the form which, with modifications, it has ever since retained. It occupies a middle position between diocesan Episcopacy and Congregationalism, and may be styled ecclesiastical republicanism. The congregation elects its own minister and elders, and by deacons or managers regulates all its financial affairs. The session, consisting of the minister and elders, has the spiritual oversight of the congregation. The ministers, with one or more elders from each congregation, constitute the presbytery (formerly sometimes called *classis*) of a defined district, having a general superintendence of the congregations; to it appeal may be made from congregations or sessions. Some churches still retain as part of the regular organisation the synod, consisting of a number of presbyteries in a province, and a court of appeal from presbyteries; other churches dispense with this intermediate court. The General Assembly or General Synod is the highest court, and consists of all the presbyteries or their representatives.

Presbyterianism was for a short time dominant in England, but is now most fully represented in Scotland, the north of Ireland, the British Colonies, and the United States. 'The alliance of the Reformed Churches holding the Presbyterian System' was founded at London in 1875, and has held 'Pan-Presbyterian' councils at Edinburgh (1877), Philadelphia (1880), Belfast (1884), London (1888), Toronto (1892), and Glasgow (1896), with Washington (1899) to follow. All churches are eligible 'having a creed in harmony with the consensus of the Reformed Confessions.' In 1896 there were 28 Presbyterian churches on the continent of Europe, 12 in the United Kingdom, 16 in North America, 7 in Australia, 2 in New Zealand, and 21 scattered over the rest of the world—86 in all, of which 67 were in the alliance. There were in all 29,364 Presbyterian church buildings, 25,477 ministers, and 4,627,140 communicants.

England.—The principles of the Puritans (q.v.) were essentially Presbyterian, although many of them were so much occupied with questions of doctrine and discipline, and with resistance to power exercised, as they believed, contrary to the word of God, that they paid little heed to the development of their principles in church government. Yet in 1572 a presbytery was formed at Wandsworth, in Surrey, by ministers of London and its neighbourhood, separating from the Church of England; and other presbyteries were soon formed, notwithstanding the extreme hostility of Queen Elizabeth. When the Westminster Assembly met in 1643 the Puritans of England were generally inclined to adopt Presbyterianism as their system of church government, although some still preferred a modified Episcopacy, and some had adopted the principles of Independency or Congregationalism. The Presbyterians were, however, the strongest party at the beginning of the Civil War, although the Independents gained the ascendency afterwards. The establishment of Presbyterian church government in the Church of England was voted by parliament (the Long Parliament), 13th October 1647; but it was never really established. The influence of the Independents prevented it. London and its neighbourhood were, meanwhile, formed into twelve presbyteries, constituting the Provincial Synod of London, which continued to hold regular half-yearly meetings till 1655, the meetings of presbyteries being continued till a later date; but the whole Presbyterian system was overturned by Cromwell's Committee of Triers, appointed for the examining and approving of all persons elected or nominated to any ecclesiastical office. Cromwell's policy aimed at bringing all ecclesiastical matters under the immediate control of the civil power. The Restoration was followed by the fruitless Savoy Conference (q.v.), and soon after by the Act of Uniformity, which came into force on 24th August 1662; and on that day about 2000 ministers in England and Wales resigned their benefices, or submitted to be ejected from them, for conscience' sake. The first Nonconformists were mostly Presbyterians, but a small minority of Independents among them prevented the institution of a regular Presbyterian system, and the consequence was that the Nonconformists of England became in general practically Independent. Antinomianism and Arminianism soon appeared among them, and were followed by Socinianism or Unitarianism to such an extent that the name *Presbyterian* became synonymous in England with *Socinian* or *Unitarian;* old endowments, legacies of Presbyterians, being in many instances enjoyed by Unitarians. Meanwhile, there sprang up in England a few congregations connected with the Church of Scotland, and with what was formerly known as the 'Secession Church,' now the United Presbyterian Church. The number of such afterwards very much increased. At the time of the formation

of the Free Church of Scotland (q.v.) the greater number of the English Presbyterian churches connected with the Church of Scotland sympathised with the cause of the Free Church, and took the name of the Presbyterian Church in England. In 1876 a union, which had been long desired, was consummated between the synod more intimately related to the Free Church of Scotland and the congregations belonging to the United Presbyterian Church. The name assumed by the united church is the Presbyterian Church of England. At the time of the union the Presbyterian Church in England had about 150 churches, and the United Presbyterian Church more than 100. At the same date the Church of Scotland in England had about twenty congregations.

Scotland.—The Presbyterian Churches of Scotland are separately treated in the articles SCOTLAND (CHURCH OF); FREE CHURCH OF SCOTLAND and UNITED PRESBYTERIAN CHURCH, now the UNITED FREE CHURCH (q.v.); and CAMERONIANS.

Ireland.—The Irish Presbyterian Church originated in the settlement of Ulster by Scottish colonists during the reign of James I. After various struggles a Presbyterian church was founded by the formation of a presbytery at Carrickfergus in 1642. The Presbyterian population of Ulster was greatly increased in number by immigration from Scotland about the middle of the 17th century; and, notwithstanding many difficulties, from the opposition of prelates and of the civil power, the church continued to increase. It is a curious fact that the Presbyterian ministers received a pension from government, under Charles II., in 1672, which *Regium Donum* (q.v.), however, was not regularly paid until the reign of William, when it was augmented, although only to the paltry amount in all of £1200 a year. It was afterwards repeatedly augmented, till it reached the amount of £70 for each minister. A seminary for the education of ministers was erected at Killaleagh; and in 1710 the synod of the Presbyterian Church resolved to institute the preaching of the gospel to the Irish in their own language. During this period of its history the Irish Presbyterian Church experienced the utmost opposition from the High Church party. Afterwards dissensions sprang up within it, and these with reference to the most important doctrines. A body opposed to the doctrine of the Westminster Confession of Faith was organised as the Presbytery of Antrim. But the doctrine of the Westminster Confession was more and more departed from in the Irish Presbyterian Church itself, which became to a large extent Arian or Unitarian. In 1830 a separation took place from the Arians, who then formed the *Remonstrant Presbytery of Ulster*. In 1840 a union took place of the Irish Presbyterian Church forming the *Synod of Ulster* and the *Secession Church in Ireland*, an offshoot of the Scottish Secession Church, which then reckoned 141 congregations in the north of Ireland. The Irish Presbyterian Church, adhering to the Westminster Confession, in 1889 had 620 ministers, with 102,057 communicants (Presbyterian pop. at 1891 census, 446,687), and it has not only displayed much zeal for the advancement of Protestantism in Ireland, but also of Christianity in other parts of the world, and supports a very successful mission in Gujarat and Manchuria. The act disestablishing the Irish Church in 1869 provided also for the discontinuance of the *Regium Donum* to the Presbyterians, with reservation of annuities for life to ministers already entitled to it: and further gave power for commutation of annuities for a capital sum, of which advantage has been taken to a very large extent, so that a fund has been formed for paying annuities and leaving a large surplus as the nucleus of a Sustentation Fund for the ministers in time to come. There are two colleges—one purely theological, at Belfast, with seven professors; the other, at Londonderry, has eight professors and a complete curriculum. The colleges were empowered in 1881 jointly to grant degrees in theology.

United States.—The first Presbyterians in America were emigrants from Scotland and Ireland. The first Presbyterian congregations in America were organised in Maryland before the close of the 17th century—the oldest that of Rehoboth, dating about 1690—and the first presbytery in Philadelphia in 1705. A synod, consisting of four presbyteries, was constituted in 1716. Dissensions ensued; but in 1758 the American Presbyterian churches were united in one; and in 1788 a General Assembly was instituted, the whole number of congregations being then 419, and of ministers 188. The increase of the church was rapid, and in 1834 it contained 22 synods, 111 presbyteries, and about 1900 ministers. In 1801 a scheme of union was adopted between Presbyterians and Congregationalists, under which hundreds of congregations were formed in the state of New York and elsewhere. About the beginning of the 19th century the Cumberland Presbyterians (q.v.) separated from the main body; and in 1838 the American Presbyterian Church was divided into two great sections, commonly known as *Old School* and *New School* Presbyterians, the former holding high Calvinistic doctrines, the latter a somewhat modified Calvinism. Both of these churches are extended over the whole of the United States, and both of them have missions in different parts of the heathen world, their collections for missions forming a large part of the contributions for that object from the United States of America. For some years they showed symptoms of a sincere desire to reunite; and this object they accomplished in 1869, notwithstanding the dissensions and new divisions caused by the struggles between the Northern and Southern States on the question of slavery. At the time of this union the Old School Presbyterians counted 2381 ministers, 2740 churches, and 258,903 communicants; while the New School numbered 1848 ministers, 1631 churches, and 170,562 communicants. Each possessed at the same time five theological seminaries. A revision of the Confession has been carried out since 1890. There are several sections of the Presbyterian Church in the United States, each having its own theological seminaries and colleges, such as the Presbyterian Churches Northern and Southern, the Cumberland, the Reformed, the United Presbyterian, the Reformed Dutch and German, &c. In 1890 the number of ministers was over 11,000, and of communicants, 1,587,790.

British Colonies.—By the middle of the 18th century Presbyterian ministers were labouring in Nova Scotia and Quebec, the various divisions of the home churches being represented at an early stage; but most of the early ministers came from the Secession Church. A union between the sections representing the Free and United Presbyterian Churches took place in 1861. The Presbyterian Church in Canada is strong and prosperous, with six theological colleges. In 1890 there were above 800 ministers, and about 140,000 communicants. In the Australasia colonies Presbyterianism is also vigorous; see articles on the several colonies. In the Cape Colony and minor colonies Presbyterianism is also represented.

On Presbyterianism, as against Episcopacy and Independency, see, in the 17th century, works by Gillespie, Rutherford, Baillie, 'Smectymnuus,' Byfield, Baxter, Clarkson; in the 18th, Welles, Hall, John Brown, Whytock; later, Barnes, *Scriptural Argument for Episcopacy Examined* (1835), and *The Apostolic Church* (1843);

The Plea of Presbytery (1840); Miller, *Manual of Presbytery* (1842); Smyth, *Presbytery the Scriptural Polity* (1843); King, *Church Government* (1854); Macpherson, *Presbyterianism* (1883); Bannerman, *Worship of the Presbyterian Church* (1884); *Constitution and Law of the Church of Scotland* (1884); Witherow, *Form of the Christian Temple* (1889); Killen, *The Framework of the Church* (1890); works on the Westminster Assembly and its Confession of Faith by Hetherington (new ed. 1891), Hodge (1869), Macpherson (1881), Mitchell (1867, 1883, 1886). See also the articles in this work on CALVIN, KNOX, ASSEMBLY (GENERAL), ELDER, CHURCH HISTORY, REFORMATION, CONFESSIONS, WESTMINSTER ASSEMBLY. For Presbyterian missions, see MISSIONS. For Presbyterianism in England, see Madrie, *Annals of English Presbytery* (1872); Drysdale's *History of the Presbyterians in England* (1889); *Minutes of the Manchester Presbyterian Classis* (Chetham Society, part i.–iii. 1890–91). For Ireland, see IRELAND; also Reid. *History of the Presbyterian Church in Ireland* (1867); Irwin, *Irish Presbyterianism* (1890). For America, see Webster, *History of the Presbyterian Churches in America* (1857); Gillett, *History of the Presbyterian Church in the United States* (1864); *American Presbyterianism* (1885).

Presbytery. For presbytery as a part of Presbyterian church government, see the preceding article. In ecclesiastical architecture the presbytery is the space in the choir of a church in which the high altar is placed; the name is sometimes extended to the whole choir.

Prescot, a manufacturing town of Lancashire, 8 miles E. by N. of Liverpool. It has manufactures (introduced from Yorkshire in 1730) of watch-movements, watch-tools, small files, &c., and there are potteries near it. Prescot was the birthplace of John Kemble. Pop. (1851) 7393; (1891) 6745.

Prescott, till 1891 the capital of Arizona, lies in a picturesque mountain-valley, some 6000 feet above the sea-level. There is a railway (74 miles north) to Prescott Junction, which is on the Atlantic and Pacific Railroad, 595 miles SW. of Denver. Gold and silver are found in the neighbourhood, and daily lines of the United States Mail Coaches connect it with the numerous mining camps round about. Besides bullion, it has a trade in lumber and wool. Pop. 1759.

Prescott, WILLIAM HICKLING, historian, was born at Salem, Massachusetts, May 4, 1796. His father was a prosperous lawyer; his grandfather, Colonel William Prescott (1726–95), was a distinguished soldier in the Revolution, to whose memory a statue was erected on Bunker Hill in 1881. He entered Harvard College in 1811, and graduated in 1814. Early in his college course he had his left eye blinded by a piece of bread playfully thrown by a fellow-student, and the other was soon sympathetically affected, so that he was obliged to live for months in a darkened room. He next travelled in England, France, and Italy, married in 1820, and abandoned the study of law for literature. He now devoted himself to severe study, and formed splendid literary projects, in spite of the grievous disadvantage of being able only to use his remaining eye for brief periods. His first studies were in Italian literature, and it was not till the beginning of 1826 that he had found the work of his life within the range of Spanish history. Fortunately his means were ample, so that he was able to procure the services of assistants, and to live amid conditions of comfort. By constant habit he gained the power of carrying a great deal in his memory, and after he had revolved the whole of a chapter in his mind he quickly transferred it to paper by means of his stylus and an ingenious writing-case specially constructed for the blind. His first secretary knew no Spanish, yet he went through the seven quarto volumes of Mariana's History with him. So he laboured with almost unexampled courage and patience at his *History of Ferdinand and Isabella* (3 vols. Boston, 1838), which quickly carried his name across the ocean to the Old World, and was straightway translated into French, Spanish, and German. He next devoted six years to the *History of the Conquest of Mexico* (3 vols. 1843), and four years to the *Conquest of Peru* (2 vols. 1847). These works deservedly brought him a great reputation; he was chosen a corresponding member of the French Institute, and on a visit to Europe in 1850 was received with the highest distinction. In 1855 he published two volumes of his *History of Philip II.*, and a third volume in 1858, but died of apoplexy before its close at Boston, January 28, 1859. Prescott's style alone would have assured him popularity, and to this day he remains unrivalled among English historians for vigorous and direct narrative and for sustained splendour of colour. His imagination worked all the more freely because he saw but with the inward eye, and the splendid visions that it wove gave his pages the vivid colours of reality and life. He is not a philosophical historian, but he is a master of narrative and incident, and there is not a dull passage in all his histories.

See the complete edition of Prescott's works in 15 volumes by his secretary, J. Foster Kirk (1884; new ed. 1889); and the Life of him by George Ticknor (1864; new ed. Lond. 1875).

Prescription is the written direction given by physician or surgeon to the chemist, and may demand an officinal or an extemporaneous compound. Officinal compounds (or preparations, as they are frequently termed) are those for which formulæ are introduced into the national pharmacopœias, and are therefore supposed to be always at hand in the laboratory of the dispensing chemist (such, for example, as *Mistura Ferri Composita*, *Pulvis Ipecacuanhæ Compositus*—i.e. Dover's Powder—*Confectio Sulphuris*, &c.); while extemporaneous compounds are those which are devised on the instant with the view of meeting the various peculiarities which almost every case of disease presents. In some cases, where no chemical action is apparent or probable, a mixture of two or more drugs seems to modify the physiological effect of each ingredient. For example, Dover's Powder contains as its active ingredients ipecacuanha and opium, and yet in well-regulated doses it neither exhibits the nauseating properties of the former nor the narcotic influence of the latter substance. The selection of the most eligible form of the remedy is of extreme importance. The physician here has to determine whether he shall prescribe his remedy in the form of pill, powder, or mixture; whether he shall administer it as an injection into the lower bowel; whether the patient shall (in certain cases) inhale it; &c. As a general rule we should accommodate the form and flavour of our remedies, provided we do not sacrifice their virtues, to the taste of the patient, who usually prefers pills to draughts or powders. The unpleasant taste of many medicines which must be given in the fluid form may often be obviated by the skill of the prescriber. Castor-oil, cod-liver oil, and copaiba are most easily taken on the surface of orange-wine, or water containing a bitter tincture, care being taken to moisten with water the edge or rim of the glass at the part applied to the mouth. The taste of solution of potash and of lime-water is best covered with milk; and the disagreeable flavour of senna is said to be concealed if its infusion is made with strong tea.

In conclusion it may be remarked that it is the custom to write prescriptions in the Latin language, to abbreviate well-known words, to use symbols for weights and measures, and to

commence each prescription with the symbol ℞, which signifies *Recipe*, 'take.' As an illustration, we append a prescription for a tonic draught (where *f.* ℥ stands for fluid ounce; *f.* ℥ for fluid drachm; ♏ for minim; *gr.* for grain; M. for *misce*, 'mix'):

(*Name of Patient.*)

℞	Quinia Sulph.,	*gr.* j
	Tinct. Calumbæ,	*f.* ℥i
	Acid. Sulph. Dilut.,	♏x
	Syrup. Aurant.,	*f.* ℥iss
	Infus. Calumbæ,	*ad f.* ℥j
M.	*Fiat Haustus ter quotidie sumendus.*	

Date. (*Initials or name of prescriber.*)

As a parallel to this retention in western Europe of a mediæval usage, it may be mentioned that in the palmy days of the republic of Athens the Attic-speaking practitioner was held bound to write his prescriptions in the ancient Doric dialects; the reason in this case being that the schools of medicine in the Doric colonies of Magna Græcia and elsewhere were long the most celebrated.

Prescription, in Roman law, means a clause inserted in the preface to the formula under which an action was tried. The prescription *longi temporis* directed that the claimant should not succeed if the defendant had been so long in possession of the property in dispute that equity would not allow him to be disturbed. In England lapse of time may affect property rights in various ways. The right of a claimant to bring an action may be taken away by statutes of Limitation (q.v.), or the law may regard the long enjoyment of the possessor as evidence to show that his rights had a lawful origin. Possessory title to land is now gained under the express provisions of the modern statutes of limitation. In proving title by prescription to easements (such as rights of way, ancient lights, &c.) and other incorporeal rights over the land of another the claimant relies on immemorial enjoyment; but the courts would always infer the immemorial character of the right from a comparatively short period of actual enjoyment. And now, under the Prescription Act of 1832, the period is fixed at twenty years in the case of lights and other easements and thirty years in the case of profits (such as common of pasture, and the like). For the rules of the act, see Shelford's *Real Property Statutes*.

In the law of Scotland prescription is a method both of acquiring and of losing a right; hence it is divided into positive and negative. The positive prescription was introduced by Statute 1617, chap. 12. As that statute has been interpreted by decisions, possession of heritable subjects for forty years, on the requisite titles, recorded in the appropriate register, is sufficient to secure an owner against any one alleging a better title; or to determine the extent of an estate, where a question arises either as to what is comprehended under a general description or as to whether a specific piece of property has been carried under a clause of parts and pertinents; or to merge a title of property in the higher title of superiority. The possession must be uninterrupted and co-extensive with the right claimed. The Conveyancing Act, 1874 (37 and 38 Vict. chap. 94 sect. 34), simplified the title necessary for founding prescription, by enacting that 'any *ex facie* valid, irredeemable title,' recorded in the appropriate register, shall be sufficient; and shortened the prescriptive period by enacting that possession for twenty years continually and together, following on such recorded title, shall be equivalent to possession for the old period of forty years.

The negative prescription of obligations was first introduced by the Statute 1469, chap. 29, which declares that unless a person follow an obligation and take document thereon within forty years, his right shall prescribe and be of no avail. By the Act 1617, chap. 12, this prescription was extended to heritable bonds and other heritable rights, and it was enacted that the years of minority of the party against whom the prescription was used should not be counted. In addition to these long prescriptions there are several shorter prescriptions, whose object, generally speaking, is to protect parties against the consequences of negligence in preserving vouchers and, after the expiration of the prescriptive period, to change the *onus probandi* and to restrict the mode of proof. Among these lesser prescriptions are the vicennial prescription of twenty years, applicable to retours and holograph writings; the ten years' or decennial prescription, applicable to actions against tutors and curators; the septennial prescription of cautionary obligations; the sexennial prescription of bills of exchange; the quinquennial prescription of arrears of rent in an agricultural lease, of ministers' stipends, of bargains concerning movables made verbally, and of inhibitions; the triennial prescription, introduced by the Act 1579, chap. 83, applicable to actions for servants' wages, for house-rents, or for accounts to attorneys, surgeons, agents, &c. In Scotland if, within twenty years after the commission of a crime, no step has been taken to bring the offender to justice, it would appear that the right to prosecute falls to the ground.

Presentment. See CRIMINAL LAW.

Preserved Provisions. Under the term *preserves* is usually included fruit, eaten whole or broken, or the juice of fruit, preserved by boiling with sugar. Whole fruit is boiled in clear syrup in such a manner that the sugar penetrates the fruit completely. It is then drained and dried at a gentle heat, so that the absorbed sugar crystallises in the substance and on the surface of the fruit, which is then known as *candied*. Jam consists of fruit boiled with an equal weight of sugar, which latter dissolves in the fruit juice set free as the fruit breaks down. If well made they can be preserved in this manner for years, but the quality deteriorates after twelve or eighteen months, owing to crystallisation and other changes taking place in the sugar. Fruit jellies consist of the juice of the fruit only, boiled with sugar, this vegetable jelly consisting principally of a substance known to chemists under the name of *pectin*. Fruits are also preserved by covering with water in suitable vessels, heating to a high temperature, and closing the vessel whilst hot.

Meat, vegetables, and other provisions may be preserved with more or less success in a number of ways, which may be classed roughly under four headings: (1) desiccation; (2) use of cold; (3) by chemical compounds (antiseptics); (4) by exclusion of air. The simple process of drying is effective both with meat and vegetables, and if completely carried out prevents the ordinary putrefactive changes from taking place. Dried vegetables are prepared largely for use on board ship, and the soup tablets so extensively used nowadays consist of meat and vegetables dried and pressed together. Jerked Beef (q.v.) and Pemmican (q.v.) are prepared chiefly by drying in the sun. The use of cold is mainly a temporary expedient employed for the carriage of meat from one country to another. This industry is carried on extensively in America, Australia, and New Zealand. The carcass is frozen hard by a refrigerating machine, and packed on board ship in a chamber cooled by a similar apparatus. Meat so preserved arrives in Europe in good condition, and if properly thawed is superior to all but the best home-grown beef

and mutton (see REFRIGERATION). For condensed milk, see MILK.

Certain chemical substances have the power to prevent decay or arrest putrefactive changes, by destroying the activity of the germs or ferments which act as the exciting cause. Common salt is variously applied for the purpose of preserving meat (the food-value being thereby somewhat decreased); the meat may be immersed in brine, packed in salt, rubbed with salt and dried, or salted and smoked. The method of salting and smoking ham is described at HAM; the chief preservative element in the wood-smoke is creasote. Creasote, boric acid, salicylic acid, and sulphur compounds are all substances that can be used as food preservatives, but the objection to the use of chemical agents is that they either have a distinct taste themselves or have a toxic influence on the human body. Salicylic acid has been used in large quantities for preserving milk and other foods, but, when taken even in small doses for a lengthened period, it disturbs the animal economy; and in France any food preserved by its means is now condemned as unfit for human consumption. The use of creasote is confined to meats which are usually smoked. Boric acid has no taste, and in all probability is harmless when taken in the small quantities present in food preserved by its means. Milk, fish, poultry, and meat of all kinds may be preserved for months by its use. A very ingenious method of using this preservative has been tried with success. The boric acid is injected into the large vein of an insensible but living animal, so that it is carried in the ordinary circulation to all parts of the body, and the animal is then killed; meat so prepared has been kept fresh and palatable for about three months. Some sulphur compounds, notably the bisulphite of lime and sulphurous acid, are good preservatives, but they have an objectionable taste. The former is used by butchers as a preserver of meat in hot weather.

Exclusion of air is a method of preserving which is used almost exclusively for cooked foods. Various plans of coating meat with air-tight coating have been tried, but they have been carried little further than the experimental stage. Meat has been dipped in molten paraffin-wax, gelatine, gutta-percha, &c.—all of which exclude air; but the air, or, more correctly, the germs present in the air, are imprisoned in the tissues of the meat, and these speedily set up putrefactive changes. The only process which has successfully accomplished the desired end is by the use of high temperature to expel the air and destroy the germs, and then sealing to prevent ingress of more air. Many have claimed the credit of this invention, but in all probability it was first proposed by a M. Appert of Paris in 1810. The process as now carried on, however, is the outcome of many minds, Appert's original method simply supplying the groundwork. The various tinned meats, soups, &c. now in the market are examples of this method of preserving food. The meat, &c. is placed in tins, which are immersed in a solution of calcium chloride heated up to a temperature of 270° F., which destroys both germs and spores. The tins are previously closed, except a small pin-hole for the escape of steam. They are heated thus for about three hours, when the pin-holes are closed by solder, and the tins are allowed to cool. This process is thoroughly successful as far as mere preservation goes. Tins of meat thus treated have been opened after twenty years, and no sign of putrefaction has been noted; occasionally through some carelessness the air may not have been thoroughly removed and putrefaction ensues; such exceptions, however, are rarely met with in tins sent out by good firms. A bad tin can be detected before opening by the bulged-out appearance of the tin, the gases of decomposition pressing out the sides or ends. The objection to the process lies in the over-cooking to which the meat must be subjected. This impairs both the appearance and flavour, and no doubt removes some of the nutritive value of the meat, although this latter point is denied by some. Other plans, varying somewhat in detail but similar in principle, have been patented, and are in use in some of the food-preserving factories. Aberdeen and London are centres for this industry, the former having five factories, whilst in America and New Zealand (q.v.) a large amount of capital is invested in the trade. See SALMON.

The various extracts of meat are in a way preserved foods. They consist of the juice and extractive matter of the meat evaporated down to a thick consistence, and frequently preserved by a large addition of salt. The majority of these extracts are stimulants rather than foods, some of them being practically useless. Vegetables are frequently preserved by the process of pickling. The vegetables are boiled with vinegar and spices. The latter two substances, being antiseptic in their nature, prevent putrefaction and decay. For the preservation of wood, see DRY ROT.

Presidency. See INDIA.

President of the United States, the head of the executive of the United States, is also the only executive officer who reaches his position by election; the appointment of the others being either in his hands (subject to their confirmation by the senate) or regulated by law. The president is elected for a term of four years; seven presidents—Washington, Jefferson, Madison, Monroe, Jackson, Lincoln, and Grant—have been chosen for a second term of office, but a third term, although there is nothing in the constitution to prevent it, is practically prohibited by the popular prejudice against it. A candidate must be a natural-born citizen of the United States, not under thirty-five years of age. The president has a salary of $50,000 a year, and must receive no other emolument during office from the United States or any state. He is commander-in-chief of the army and navy of the United States, and of the militia when in the actual service of the Union; he has the power to grant reprieves and pardons for offences against the United States, except in cases of impeachment, and (by and with the advice and consent of two-thirds of the senate) to make treaties and to appoint ambassadors, consuls, and all other officers of the United States whose appointments are not otherwise provided for; from time to time he sends to congress a 'message' (cf. the 'Queen's Speech') giving information as to the state of the Union, and recommending measures for consideration; he may convene both houses, or either house, in special session; and, if the two houses disagree as to the time of adjournment, he may adjourn them to such time as he thinks fit. The president, like the vice-president and all other civil officers, may be removed from office on impeachment by the House of Representatives for and conviction by two-thirds of the senate of treason, bribery, or other high crimes and misdemeanours. He may require the opinion, in writing, of the head of any of the executive departments on any subject relating to the duties of his department. Every bill which passes congress must have the president's signature to become a law, unless, after he has returned it with his objections, two-thirds of each house support it and pass it over his veto.

The Vice-president of the United States, although elected along with the president, is no part of the executive department. His sole function is to

preside over the senate, where he has no vote unless in the case of a tie; and in practice he has little influence on the administration, and is regarded only as an 'under-study,' in readiness to take the presidency in the event of its being vacated by the president's removal, death, resignation, or inability. Four vice-presidents—Tyler, Fillmore, Johnson, Arthur—have so succeeded to the presidency. In the event of the removal, death, resignation, or inability of both the president and the vice-president, the secretary of state, and after him, in their order, other members of the cabinet, would act as president until the disability of the president was removed, or a new president elected. On the death of a vice-president the duties of his office are fulfilled by the president *pro tempore* of the senate.

The election of president and vice-president is controlled by the electoral system, under which the people do not vote directly for the candidates, but for electors from their separate states who are pledged to cast their votes for particular candidates. Each state is entitled to a number of electors equal to its number of senators (two in each case) and representatives in congress; these latter range from one to thirty-four (see table below). At first the electors simply voted for two candidates, and the one who received the second highest number of votes for president became vice-president; but since 1804 provision has been made for a separate election of the vice-president. In the event of no candidate having a majority of the electoral votes the House of Representatives chooses a president, voting by states, each state having one vote; if no vice-president is elected the senate chooses a vice-president, voting as usual. Such cases occurred in 1800–1, when Jefferson and Burr had tied, and the former was made president and the latter vice-president; in 1824–25, when none of the four candidates for the presidency had a majority, and John Q. Adams, who had received eighty-four electoral votes, was chosen by the House over Andrew Jackson, who had ninety-nine; and finally in 1836–37, when Richard M. Johnson, who had obtained a plurality of electoral votes for the vice-presidency, was elected by the senate. The territories have no vote in any case.

For other presidents, see the articles on the several republics that have such officers at the head of the government.

The presidents of the United States have been George Washington (1789–97), John Adams (1797–1801), Thomas Jefferson (1801–9), James Madison (1809–17), James Monroe (1817–25), John Quincy Adams (1825–29), Andrew Jackson (1829–37), Martin Van Buren (1837–41), William Henry Harrison (March–April 1841), John Tyler (1841–45), James Knox Polk (1845–49), Zachary Taylor (1849–50), Millard Fillmore (1850–53), Franklin Pierce (1853–57), James Buchanan (1857–61), Abraham Lincoln (1861–65), Andrew Johnson (1865–69), Ulysses S. Grant (1869–77), Rutherford Birchard Hayes (1877–81), James Abram Garfield (March–September 1881), Chester Alan Arthur (1881–85), Grover Cleveland (1885–89), Benjamin Harrison (1889–93), Cleveland (1893–97), William McKinley (1897, 1900). See separate articles. The following table shows the number of electoral votes allowed to each state since the census of 1890:

Alabama	11	Maine	6
Arkansas	8	Maryland	8
California	9	Massachusetts	15
Colorado	4	Michigan	14
Connecticut	6	Minnesota	9
Delaware	3	Mississippi	9
Florida	4	Missouri	17
Georgia	13	Montana	3
Idaho	3	Nebraska	8
Illinois	24	Nevada	3
Indiana	15	New Hampshire	4
Iowa	13	New Jersey	10

Wisconsin	12		
Wyoming	3		
Total	444		

Presidio, a Spanish word for 'a fort,' applied especially to four Spanish fortified posts on the coast of Morocco—Ceuta, Melilla, Alhucemas, and Peñon de Velez.

Press, Freedom of the, the expression used to denote the absence of any official restraint on the publication of books and other printed matter. In England, at the Reformation, the control of the press came to be centred in the crown, the ecclesiastical in addition to the secular government being vested in Henry VIII. as temporal head of the church. The Company of Stationers, who came to have the regulation of printing and publishing, were servants of the government, subject to the control of the Star Chamber. The censorship of the press was enforced by the Long Parliament, in spite of Milton's eloquent protest (see his *Areopagitica*), and was re-established more rigorously at the Restoration. It was continued at the Revolution, and the statute regulating it was renewed from time to time till 1693, when the Commons by a special vote struck it out of the list of temporary acts to be continued. Since that time the censorship of the press has ceased to exist in Britain. But, though there are no official restrictions on what shall and what shall not be published, the authors and publishers of criminal or injurious matter are amenable to the law of libel; and there are certain statutory requirements in force to enable them to be traced. Every person who prints anything for hire or reward must, under a penalty of £20, keep one copy at least of the matter printed, and write on it the name and place of abode of the person who employed him to print it. Every person who prints any paper meant to be published must print on the first or last leaf his name and usual place of business; and on failure to do so he forfeits the sum of £5, and so does any person publishing the same. There are a few printed papers exempted from conforming to the above requirement—as, for instance, papers printed by parliament or in government offices, engravings, auction lists, bank-notes, bills of lading, receipts for money, and a few other similar matters. In the case of a libel legal publication is constituted by sending or showing a copy printed or in manuscript to any person; the sale of a newspaper or other publication in a shop, or its delivery to an officer at the Stamp-office, is also considered an act of publication. The truth of the statements published may be urged as a plea of defence in an action for libel; in criminal proceedings truth is a defence if the publication is for the public benefit. The publisher of a book or newspaper may also defend himself by showing that the matter complained of was published by order of either House of Parliament, that it is a fair criticism on a public person or act, or that it represents the honest belief of the defendant, and is published by him in the course of his official or moral duty. If a bill shall be filed in any court for the discovery of the name of the printer, publisher, or proprietor of a newspaper or other publication, with the view of rendering him liable in damages for slanderous matter, the defendant is bound to make the discovery required, which, however, cannot be made use of against him in any other proceeding than that for which it has been made. The penalties against newspapers can only be sued for in the name of the Attorney-general or Solicitor-general, or Lord Advocate. Certain regulations also exist regarding the exhibition of Plays (q.v.). Subject to these restrictions, the freedom of the press has subsisted in Britain since 1693. At least an equal degree of freedom obtains in the United States, where privilege is much more widely extended. See Libel.

A more or less rigorous censorship of the press

exists in most European states. There is often no direct supervision previous to publication, but the official censor has it in his power to stop any publication which he deems objectionable, to confiscate the edition, and to prosecute the author and editor. Newspapers and pamphlets are generally subjected to a stricter censorship than larger works. See INDEX; also Odgers on Libel, and Paterson on the Liberty of the Press.—For Correction of the Press, see PROOFS.

Pressensé, EDMOND DE, a prominent French Protestant theologian, was born in Paris, January 24, 1824, studied at the university there, next under Vinet at Lausanne, and Tholuck and Neander at Halle and Berlin, and in 1847 became a pastor at Paris. He was deputy to the National Assembly for the Seine department in 1871–76, and was elected a senator for life in 1883. He received the D.D. degree from Breslau in 1869 and Edinburgh in 1884. He died April 8, 1891. A strong thinker and vigorous writer, as well as eloquent preacher, Pressensé took a foremost part in the great theological as well as ecclesiastical controversies of the day; published many learned and important books, most of which have been translated into English and German; and contributed to the theological and literary magazines on both sides of the Channel—the article on CHRISTIANITY in the present work is from his pen.

The following are the most important books: *Le Rédempteur* (1854; Eng. trans. 1864); *Histoire des Trois Premiers Siècles de l'Église Chrétienne* (4 vols. 1858–77; Eng. trans. 1869–78; a thoroughly revised and extended edition had reached its third volume in 1890); *L'Église et la Révolution Française* (1864; Eng. trans. 1869); *Jésus Christ, son Temps, sa Vie, son Œuvre* (1866; Eng. trans. 1866); *Études Contemporaines* (1880; Eng. trans. New York, 1880); and *Les Origines* (1882; Eng. trans. 1883).

Pressgang. Impressment was the mode formerly resorted to for manning the British navy. The practice had not only the sanction of custom, but the force of law. It may be traced in English legislation from the days of Edward I.; and many acts of parliament, from the reign of Philip and Mary to that of George III., were passed to regulate the system of impressment. Impressment consisted in seizing by force, for service in the royal navy, seamen, river-watermen, and at times landsmen, when state emergencies rendered them necessary. The pressgang, an armed party of reliable men commanded by officers, usually proceeded to such houses in the seaport towns as were supposed to be the resort of the seafaring population, laid violent hands on all eligible men, and conveyed them forcibly to the ships of war in the harbour. As it was not in the nature of sailors to yield without a struggle many terrible fights took place between the pressgangs and their intended victims —combats in which lives were often lost. In point of justice there is little, if anything, to be said for impressment, which had not even the merit of an impartial selection from the whole available population. Under the laws all eligible men of seafaring habits were liable between the ages of eighteen and fifty-five; but exemptions were made in favour of apprentices who had not been two years apprenticed, fishermen at sea, a proportion of able seamen in each collier, harpooners in whalers, and a few others. A pressgang could board a merchant-vessel or a privateer of its own nation in any part of the world, and carry off as many of the best men as could be removed without actually endangering the vessel. The exercise of this power made a privateer dread a friendly man-of-war more than an enemy, and often led to as exciting a chase as when enemies were in pursuit of each other; for the privateer's men were the best sailors, for their purpose, that the naval officers could lay hold on. Mitigations of the harsh laws on the subject were frequently introduced. As early as 1563 the naval authorities had to secure the sanction of the local justices of peace; in 1835 the term of an impressed man's service was limited to five years save in urgent national necessity. By that time the system was becoming obsolete; the navy is now manned by voluntary service. In recent times, when volunteers fail, a system of bounties has been resorted to. But the laws sanctioning impressment slumber, without being repealed.

Pressing to Death. See PEINE FORTE ET DURE.

Prester John, the name applied by mediæval credulity for two hundred years to the supposed Christian sovereign of a vast but ill-defined empire in central Asia. The idea of a powerful Christian potentate in the far East, at once priest and king, was universal in Europe from about the middle of the 12th to the beginning of the 14th century, when it was transferred to Ethiopia and finally found a fancied historical justification in identification with the Christian king of Abyssinia.

The first mention of a Prester John, sprung from the ancient race of the Magi of the Gospels, occurs in the Chronicle of Otto, bishop of Freisingen. Here, on the authority (1145) of the bishop of Gabala (*Jibal* in Syria), we find a circumstantial account of his power, his Christianity after the Nestorian pattern, his victories over the Medes and Persians, and how his progress to Jerusalem was stayed by the intervening Tigris, which refused to freeze over to give him passage. Again, about 1165, there was widely current in Europe an extravagant epistle supposed to be addressed by Prester John to the Greek emperor Manuel. Herein we read astounding wonders enough: how that he ruled over the three Indies and countless hordes of men, among them those unclean races which Alexander the Great shut up within the northern mountains; that thirteen great crosses of gold and jewels were borne before as many armies, each of 10,000 knights and 100,000 foot; that all his subjects were virtuous and happy; attendant upon him were seven kings, sixty dukes, and 365 counts, twelve archbishops, and twenty bishops, while seventy-two kings with their kingdoms were his tributaries; before his throne stood a wondrous mirror, in which he saw everything that was happening in all his vast dominions; his kingdom contained the Fountain of Youth, the Sea of Sand, the River of Stones, and the river whose sand was precious gems, ants that dug gold, fish that yielded purple, pebbles that give light and make invisible, and the salamander which lives in fire, from the incombustible covering of which were fashioned robes for the presbyter to wear. There is also extant a letter of date 1177, written by Pope Alexander III. and evidently addressed to the imaginary author of the grandiloquent epistle of 1165.

About the year 1221 the distant rumour of the conquests of Genghis Khan again gave strength to the belief in such a mighty Christian potentate. M. d'Avezac first pointed out the true historical source of the story in the Chinese Yeliu Tashi, founder of the empire of Karâ-Khitâi, who assumed the title of Gur Khân (supposed by Oppert to have been confounded with *Yukhanan* or *Johannes*), and fixed his capital at Balasaghun, north of the T'ian Shan range. He defeated Sanjar the Seljuk sovereign of Persia in 1141 at a great battle near Samarkand, but, though hateful to the Moslem historians, of course never made any profession of Christian faith. Professor Bruun of Odessa identifies Prester John with the 12th-century Georgian prince John Orbelian, a redoubtable enemy of the Turks

(see Colonel Yule's *Marco Polo*, 2d ed. 1875, app. to vol. ii.). Many writers about the close of the 13th century, as Marco Polo, the Sieur de Joinville, and even Gregory Abulfaraj, identify him with Ung Khán, king of the Nestorian tribe of Kerait. Friar Odoric about 1326 visited the country—the Tenduc of Marco Polo—still ruled over by a prince whom he styles Prester John, but he adds, with the cautious gravity of the true historian, 'as regards him, not one hundredth part is true that is told of him as if it were undeniable.' From this time the Asiatic phantom entirely disappears from view, but from the 14th century onwards Prester John continues a less romantic existence under the guise of the Christian king of Abyssinia.

See D'Avezac in vol. iv. (1839) of the *Recueil de Voyages et de Mémoires* of the Paris Société de Géographie; Dr Gustav Oppert, *Der Presbyter Johannes in Sage und Geschichte* (2d ed. 1870); Friedrich Zarncke, *Der Priester Johannes* (1876–79). See also Colonel Sir Henry Yule's article in *Ency. Brit.* (9th ed.), his Hakluyt Society *Cathay and the Way Thither* (vol. i. 1866), and *The Book of Ser Marco Polo* (2d ed. 1875).

Preston, an important manufacturing town of Lancashire, a municipal, parliamentary, and county borough, on the north bank, and at the head of the estuary, of the Ribble, 14 miles from the Irish Sea, 28 NNE. of Liverpool, 31 NW. of Manchester, and 209 NNW. of London. Occupying an eminence 120 feet above the river, and built mostly of brick, it is on the whole well laid out, and is surrounded with pleasing scenery. The town-hall, built in 1862–67 from designs by Sir G. G. Scott at a cost of £80,000, is a French Gothic pile, with a clock-tower and spire 195 feet high. In September 1882 were laid the foundation-stones both of the Lancashire county hall and of the Harris free library and museum, to the latter of which in 1883 Mr R. Newsham bequeathed a collection of pictures and art-treasures worth £70,000. The places of worship are all of them modern, for even the parish church has been rebuilt. St Walburge's (Roman Catholic), by Hansom of cab celebrity, has a spire 306 feet high, the loftiest built in England since the Reformation, which amply redeems 'proud Preston' from its old 'no-steeple' reproach. Other edifices are the grammar-school (1550; rebuilt 1841), the corn exchange and market-house (1824), public baths (1851), a covered market (1870), militia barracks (1856), the infirmary (1869), &c. Three large public parks were laid out in 1867—the Miller and Avenham parks, and the former unsightly 'Moor' of 100 acres to the north of the town. In the first a statue was erected in 1873 of the fourteenth Earl of Derby; in Winckley Square is a monument to Sir Robert Peel. Preston was constituted an independent port in 1843; and great improvements have been effected at a cost of over a million under the 'Ribble Navigation and Preston Dock Act, 1883,' these including the deepening of the channel so as to admit vessels of 1000 tons, construction of a dock of 40 acres (opened 1892), erection of warehouses, &c. Arkwright (q.v.), who was born here in 1732, in 1768 set up here his famous spinning-frame; and Preston now is one of the principal seats of the cotton industry, which gradually superseded the linen manufacture, its staple in the 18th century. There are also iron and brass foundries, iron shipbuilding yards, engineering and machine shops, steam-boiler works, rope-walks, &c. A guild-merchant festival, first clearly heard of in 1397, has been held regularly every twenty years since 1562—the last on 4th September 1882. Preston, the first of whose royal charters was granted by Henry VI., returns two members to parliament. The borough boundary was extended in 1885. Pop. (1811) 17,115; (1841) 50,073; (1881) 100,262; (1891) 111,696.

Preston arose whilst ancient *Coccium* or Ribchester, higher up the Ribble, decayed. In Athelstan's reign Amounderness, the hundred in which it is situated, was granted to the cathedral church of York; hence its chief town came to be known as Preston or 'priests' town.' Near Preston, on 17th August 1648, Cromwell totally routed the royalists under Sir Marmaduke Langdale; and Preston figures in both the Jacobite rebellions of 1715 and 1745. For Forster's little army surrendered here to General Willes; and Prince Charles Edward occupied the town on both his march to and his retreat from Derby. Lady Hamilton has been claimed, but falsely it seems, as a native. On 1st September 1832 Joseph Livesey of Preston and six others here signed a pledge of total abstinence—the first ever taken in England.

See works by Whittle (2 vols. 1821–37), Dobson (four, 1856–62), Hardwick (1857), Abram (1882), and T. C. Smith (1891).

Prestonpans, a coast-town of Haddingtonshire, 8 miles E. of Edinburgh. Its salt-pans flourished from the 12th century till 1825; now brewing and fishing are the principal industries. Pop. 2223. To the south-east, on 21st September 1745, was fought the battle of Prestonpans, Preston, or Gladsmuir, when in a five minutes' rush Prince Charles Edward's 2500 Highlanders completely routed 2300 disciplined soldiers under Sir John Cope and Colonel Gardiner (q.v.).

Prestwich, a cotton manufacturing town of Lancashire, 4 miles NNW. of Manchester, with a 13th c. Gothic church. Pop. (1891) 7869.

Prestwich, Sir Joseph (1812–96), was a London wine-merchant till he was sixty, in 1874 became professor of Geology at Oxford, and in 1896 was knighted. See the Life by his wife (1899).

Prestwick, the headquarters of golf on the Ayrshire coast, 2½ miles N. of Ayr; pop. 2000.

Presumption, an inference drawn by the law in certain circumstances, and used to start an argument. A person who has possession of goods is presumed to be the owner till the contrary is proved. A man is presumed to be innocent till the contrary is proved. The law of England presumes that any one who has not been heard of for seven years is dead. By an act of 1881 for Scotland the heir of a person who has disappeared for seven years may obtain authority to uplift the annual income, and thirteen years later may obtain full possession of the heritable estate of the person presumed to be dead; for securing full right to inherit and dispose of movable estate, the person must be dead for fourteen years.

Pretender. See Jacobites, Stewart.

Pretoria, capital of the Transvaal, in South Africa, stands in a plain sheltered by encircling mountains, 980 miles from Capetown and 285 by rail (1893) W. of Lorenzo Marques, on Delagoa Bay. It is named from the Boer leader Andries Pretorius (died 1853), who saved the Trekkers by repeatedly defeating the Zulus, till then triumphant (see Transvaal). New public buildings were erected in 1891, and the railway hither was opened in 1893. During the Transvaal war it was formally occupied by Lord Roberts on 5th June 1900, and the new government of the city as a British town organised. Pop. 10,000.

Preventive Service. See Coastguard.

Preveza, or Previsa, a town in the south-west of Turkey, on the Gulf of Arta, exporting valonia, wool, cotton, and oil; pop. 6000.

Prévost, Abbé. Antoine François Prévost d'Exiles, commonly called the Abbé Prévost, and

immortal as the author of *Manon Lescaut*, was born of good family at Hesdin in Artois, 1st April 1697. He was educated by the Jesuits at Hesdin, and at the Collége d'Harcourt in Paris, at sixteen volunteered for service as the last war of Louis XIV. was drawing to its close, but soon returned to the Jesuits, and indeed had almost joined the order when a fresh temptation drew his impulsive and restless nature once more to the soldier's life. Of this second period of soldiering little is known, but it is certain that at twenty-four he joined the Benedictines of St Maur, and spent the next six years in a round of religious duties, in study, and in writing a volume of *Gallia Christiana*. About the year 1727, being anxious to be transferred to Cluny, where the rule was less austere, he discounted his permission, and so found himself unexpectedly guilty of the sin of disobedience. He fled to Holland, and spent six years of exile in that country and in England, and there is even a dim story of a love entanglement against which he strove for a while in vain. In 1728 he published the first and best of his long novels, the *Mémoires d'un Homme de Qualité*, to which indeed *Manon Lescaut* (apparently first published at Amsterdam in 1733) forms a kind of supplement. His fluent pen employed itself in further novels—*Cléveland, fils naturel de Cromwel; Le Doyen de Killerine*—in translations, and in *Le Pour et Contre* (1733–40), a periodical review of life and letters, modelled on the *Spectator*, and showing an excellent appreciation of English books. By 1735 he was back in France by royal permission, and allowed to wear the dress of the secular priesthood. He was befriended by Cardinal de Bissy, and the Prince de Conti, whose chaplain he became, and for thirty years he wrote assiduously over a hundred volumes of compilations, including a voluminous *Histoire générale des Voyages* (of which vol. i., 1746, contains a fine portrait by Schmidt), histories, moral essays, translations of *Pamela* and *Clarissa Harlowe*, and at least one novel—*Histoire d'une Greeque Moderne*. In 1741 a literary service thoughtlessly rendered to a satirical novelist drove him from France to Brussels, thence to Frankfort; but he was soon forgiven by M. de Maurepas, and allowed to return. He lived in a cottage at Saint-Firmin near Chantilly, walked much in the woods there, and died of the rupture of an aneurism, 23d November 1763. The story was long current that after he was thought to have died of apoplexy, a stupid surgeon, in haste to begin a post-mortem examination, both brought him to life and killed him with a single thrust of his knife; but this hideous romance first appeared about 1782, and was completely disproved by Harrisse (see his *L'Abbé Prévost*, 1896). Many other legends have clustered round Prévost's romantic life. Of these the most remarkable is a perfectly baseless calumny that he killed his own father, who had caught him in an intrigue, by throwing him downstairs.

Prévost's is one of the names lifted securely above the flood of time by one book written in a moment of happy inspiration. *Manon Lescaut* remains fresh, charming, and perennial, from its perfect and unaffected simplicity, the stamp of reality and truth throughout, and a style so flowing, easy, and natural, that the reader forgets it altogether in the overpowering pathetic interest of the story. The half-dozen figures portrayed have the likeness of life itself: the young Chevalier des Grieux, the hero, is a lover of the noblest pattern, absolutely forgetful of self, and idealising even the unworthiness of his mistress; Tiberge is an admirable type of the sensible and faithful friend, Lescaut, Manon's brother, of the ruffian and bully; but the triumph of the book is Manon herself, charming, light-hearted, shallow, incapable of a love that she will not sacrifice for luxury, yet ever moved with a real affection for her lover, constant even in her inconstancy and her degradation, the goodness ever shining through the guilt, and at last purified by love and suffering. One feels in this unique book that it is impossible to say where reality ends and fiction begins, and indeed it remains to this day unequalled as a truthful realisation of one over-mastering passion. From beginning to end a careful reader detects the traces of a sad experience, for its author had himself a sensitive heart and warm imagination, joined to a weak and vacillating character. Both a Tiberge and a Des Grieux met in himself, for his character and ideals were pure and elevated, despite the weaknesses that grew out of his passionate and impulsive soul. Compounded, like his hero, at once of weakness and of strength, he is not to be regarded with admiration so much as sympathy and affection, for, if his sensitive and impressionable heart opened a door to frailties ill-befitting the habit that he wore, these frailties at least were natural and not dissimulated, and did not corrupt his heart any more than they did his heroine's.

There is no complete edition of Prévost's works. His *Œuvres Choisies* were collected at Amsterdam (39 vols. 1783–85). Of his one masterpiece the editions are numberless, and there is at least one fair English translation, by D. C. Moylan (1841; reprinted 1886). See the biography prefixed to Prévost's *Pensées* (1764), and Sainte-Beuve in *Portraits Littéraires*, vols. i. and iii., and *Causeries du Lundi*, vol. ix.

Prévost-Paradol, Lucien Anatole, French journalist, was born at Paris, son of an actress, 8th August 1829, passed with distinction through the Collége Bourbon and École Normale, and became in 1855 professor of French Literature at Aix. Hardly a year later he was at work in Paris on the *Journal des Débats* and *Courrier du Dimanche*, and from time to time he published collections of essays on literature and politics, of which the best is his *Essais sur les Moralistes Français* (1864). In 1865 he was elected to the Academy, and in 1868 he visited England, and was honoured at Edinburgh with a public entertainment. He had always been, as a moderate liberal, an opponent of the empire, but the accession of Ollivier to power in January 1870 seemed to open up a new era for French policy, and he allowed himself to accept the post of envoy to the United States. Scarcely was he installed when the war with Germany broke out, and Prévost-Paradol, his mind unhinged by the virulent attacks made upon him by the republican press, and hopeless of the issue of the great struggle before his country, solved his own difficulties by suicide at Washington, July 20, 1870.

Prey, Birds of. See Birds of Prey.

Priam, king of Troy at the time of the Trojan war, was the son of Laomedon and Strymo or Placia. The name means 'the ransomed,' and was given him on account of his having been ransomed by his sister Hesione from Hercules, into whose hands he had fallen. His first wife was Arisba, daughter of Merops, whom he gave away to a friend in order to marry Hecuba, by whom, according to Homer, he had nineteen sons. He had altogether fifty sons; later writers add as many daughters. The best known of these are Hector, Paris, Deïphobus, Helenus, Troilus, and Cassandra. Priam is represented as too old to take any active part in the Trojan war, and in Homer only once appears on the field of battle. After Hector's death he went to the tent of Achilles to beg the body for burial. The oldest Greek legends are silent respecting his fate; but later poets like Euripides and Virgil say that he was slain by Pyrrhus when the Greeks stormed the city.

Priapus, son of Dionysus and Aphrodite, born at Lampsacus on the Hellespont, considered as a divinity of fruitfulness, especially of flocks of sheep and goats, of bees, the vine, and of all kinds of garden produce. His statues usually stood in gardens, in the form of rude wooden images, painted vermilion, with a club, sickle, and phallic symbol of exaggerated dimensions.

Pribram, a mining town of Bohemia, 48 miles by rail SSW. of Prague, employs 6000 men in the royal lead and silver mines, and various manufactures. There is a mining academy, and a church much frequented by pilgrims. Pop. 11,020.

Pribylof Islands. See ALASKA, SEAL.

Price, the exchangeable value of commodities. See CURRENCY, EXCHANGE, MONEY, VALUE, and works cited at POLITICAL ECONOMY.

Price, RICHARD, philosopher, was born at Tynton, in Glamorganshire, on 22d February 1723. His father was a dissenting minister, morose, bigoted, and intolerant, in complete antithesis to the disposition of the son. As a boy he read Clarke and Butler, went at eighteen to a dissenting academy in London, and at the close of his studies became chaplain to a Mr Streatfield at Stoke-Newington, with whom he lived for thirteen years. Legacies from his patron and an uncle in 1756 enabled him to marry. He laboured as a preacher at Newington Green and at Hackney, and established a reputation by his somewhat heavy but able *Review of the Principal Questions in Morals* (1758). His apologetic work, *On the Importance of Christianity*, appeared in 1766. In 1769 he received from Glasgow the degree of D.D., and published his *Treatise on Reversionary Payments;* which was followed by the compilation of the celebrated *Northampton Mortality Tables*, and various other works of value relating to life assurance and annuities. In 1771 appeared his famous *Appeal to the Public on the Subject of the National Debt;* in 1776 his *Observations on Civil Liberty and the Justice and Policy of the War with America.* The latter brought him the freedom of the city of London and an invitation from congress to assist in regulating its finances. Price lived long enough to herald the promise of the French Revolution, and to be denounced in Burke's *Reflections.* He died April 19, 1791. Price was a believer in the immateriality of the soul, holding that it remained in a dormant state between death and resurrection. Their difference of opinion on this subject led to a controversy of some celebrity between him and his friend Dr Priestley. His views respecting the divinity of Christ were what is called Low or semi-Arian. As a moralist he has a close affinity with Cudworth, and in some points strangely foreshadows the greater name of Kant. Of his great treatise on morals the chief positions are these: actions are *in themselves* right or wrong; right and wrong are simple ideas incapable of analysis; these ideas are received immediately by the intuitive power of the reason or understanding. See the Life by his nephew, William Morgan (1815).

Prichard, JAMES COWLES, ethnologist, was born at Ross in Herefordshire, 11th February 1786. The son of a Quaker merchant, he received a careful home education at Ross and in Bristol, where he had many chances of picking up foreign languages. There, at St Thomas's, London, and in Edinburgh he studied medicine; and in 1810, after a residence both at Cambridge and at Oxford, he commenced practice in Bristol as a physician. His talents were soon recognised. He was appointed physician first to the Clifton dispensary and St Peter's Hospital, and afterwards to the Bristol infirmary. In 1813 appeared his *Researches into the Physical History of Mankind,* which at once secured him a high standing as an ethnologist. The different editions of this work (4th, 5 vols. 1841–51) gave further proofs of the zeal with which he pursued his ethnological inquiries; and at the same time he devoted himself much to philology, which he rightly judged to be absolutely indispensable for an enlarged study of ethnology. He made himself master not only of the Romance, Teutonic, and Celtic languages, but also of Sanskrit, Hebrew, Arabic; and in *The Eastern Origin of the Celtic Nations* (1831; 2d ed. by Latham, 1857) he compared the different dialects of Celtic with the Sanskrit, Greek, Latin, and Teutonic languages, and succeeded in establishing a close affinity between them all, from which he argued in favour of a common origin for all the peoples speaking those languages. Besides several medical works, he also published an *Analysis of Egyptian Mythology* (1819; Ger. trans. by A. W. von Schlegel, 1837) and *The Natural History of Man* (2 vols. 1843; 4th ed. by E. Norris, 1855). As a tribute to his eminence as an ethnologist, Dr Prichard was elected president of the Ethnological Society; while in recognition of his researches into the nature and various forms of insanity he was appointed in 1845 a commissioner in lunacy. This occasioned his removal to London, where on 22d December 1848 he died of rheumatic fever. The first to raise ethnology to the rank of a science, he was himself a monogenist, maintaining that man is one in species, and that the negro is the primitive type of the human race.

Prickle (*Aculeus*), in Botany, is simply a hard, pointed hair. See HAIRS OF PLANTS.

Prickly Heat is the popular name in India and other tropical countries for a form of skin disease sometimes known as *Lichen tropicus* (see LICHEN). It more frequently attacks strangers from temperate climates than the natives, although the latter are not altogether exempt from it. It consists in a copious eruption of small red papules. The sensations of itching and stinging which attend it are intense, and give rise to an almost irresistible propensity to scratching, which of course only aggravates the irritation. Little or nothing can be done in the way of treatment, except keeping as cool as possible.

Prickly Pear, or INDIAN FIG (*Opuntia*), a genus of plants of the natural order Cactaceæ (q.v.), having a fleshy stem, generally formed of compressed articulations; leafless, except that the youngest shoots produce small cylindrical leaves which soon fall off; generally covered with clusters of strong hairs or of prickles; the flowers springing from among the clusters of prickles, or from the margin or summit of the articulations, solitary, or corymboso-paniculate, generally yellow, rarely white or red; the fruit resembling a fig or pear, with clusters of prickles on the skin, mucilaginous, generally eatable—that of some species pleasant, that of others insipid. The prickles of some species are so strong, and their stems grow up in such number and strength, that they are used for hedge-plants in warm countries. The Common Prickly Pear or Indian Fig (*O. vulgaris*), a native of Virginia and more southern parts of North America, is now naturalised in many parts of the south of Europe and north of Africa, and in other warm countries. It grows well on the barest rocks, and spreads over expanses of volcanic sand and ashes too arid for almost any other plant. It is of humble growth: its fruit oval, rather larger than a hen's egg, yellow, and tinged with purple, the pulp red or purple, juicy, and pleasantly combining sweetness with acidity. It is extensively used in many countries as an article of food. In the south of England the prickly pear lives

in the open air, and occasionally ripens its fruit. In America it is cultivated considerably to the north of its native region. Lime rubbish is often mixed with the soil in which it is to be planted. The fruit is imported into Britain, to a small extent, from the Mediterranean. The Dwarf Prickly Pear (*O. nana*), very similar, but smaller, and having prostrate stems, is naturalised in Europe as far north as the sunny slopes of the Tyrol. The Tuna (*O. tuna*), much used in some parts of the West Indies as a hedge-plant, and also valuable as one of the species which afford food to the cochineal insect, yields a pleasant fruit. It has red flowers, with long stamens, which display a remarkable irritability.

Pride, Thomas, one of the most resolute of Cromwell's soldiers, was a native of London, and of humble origin. At first a drayman and brewer, he enlisted at the commencement of the Civil War, and by his merit quickly rose to be colonel. He commanded a brigade under Cromwell in Scotland, and, when the House of Commons betrayed a disposition to effect a settlement with the king, was appointed by the army to purge it of its Presbyterian royalist members. By 'Pride's Purge' about a hundred were excluded, whereupon the House, now reduced to about eighty members, proceeded to bring the king to justice. Colonel Pride sat among his judges, and signed the death-warrant. He died 23d October 1658, and so felt not the rage of his enemies when his body was dug up and hanged beside Cromwell's on Tyburn.

Prideaux, Humphrey, scholar and divine, was born of an ancient and honourable family at Padstow, Cornwall, 2d May 1648. He was educated at Westminster School under Dr Busby, and then at Christ Church, Oxford, where he graduated B.A. in 1672. His *Marmora Oxoniensia* (1676), an account of the Arundel Marbles, procured for him the friendship of Lord Chancellor Finch (afterwards Earl of Nottingham), who in 1679 appointed him rector of St Clement's, Oxford, and in 1681 a prebendary of Norwich. After several minor preferments he was collated in 1688 to the archdeaconry of Suffolk, and in 1702 was made Dean of Norwich. He died 1st November 1724. His nine works include a *Life of Mahomet* (1697), long very popular; *Directions to Churchwardens* (1701; 15th ed. 1886); and *The Connection of the History of the Old and New Testament* (1715–17; 27th ed. 1876). The last treats with much learning, but less discernment, the affairs of ancient Egypt, Assyria, Persia, Judæa, Greece, and Rome, so far as they bear on the subject of sacred prophecy. See Prideaux's *Letters to John Ellis*, edited by E. M. Thompson (Camden Soc. 1875).

Pride of China (also called Pride of India and Bead-tree), a handsome tree of the order Meliaceæ (*M. azedarach*), a native of India, naturalised in the southern states of the American Union. It grows rapidly, has large bunches of flowers, and enormous quantities of small fruit. A decoction of the bark of its root is used as a vermifuge.

Prie-dieu (Fr., 'pray God'), a portable kneeling-desk; a chair which may be used for kneeling in prayer.

Priego, a town of Spain, 46 miles SE. of Cordova, grows wine and weaves silk. Pop. 15,674.

Priene, anciently one of the 'twelve' cities of Ionia, stood a little NW. of the mouth of the Mæander in Caria. Here in the second half of the 19th century the remains of an elegant Ionic temple to Athene Polias were examined by an agent of the British Society of Dilettanti, who carried off and gave to the British Museum the stone bearing the inscription that recorded its dedication by Alexander the Great. See *Antiquities of Ionia*, part iv. (1882).

Priessnitz. See Hydropathy.

Priest (Gr. *presbyteros*, Lat. *presbyter*, Fr. *prêtre*), the title, in its most general signification, of a minister of public worship, but specially applied to the minister of sacrifice or other mediatorial offices. In the early history of mankind the functions of the priest seem to have commonly been discharged by the head of each family; but on the expansion of the family into the state the office of priest became a public one. It thus came to pass that in many instances the priestly office was associated with that of the sovereign. But in many religious and political bodies, also, the orders were maintained in complete independence, and the priests formed a distinct and, generally speaking, a privileged class. The priestly order, in most of the ancient religions, included a graduated hierarchy; and to the chief, whatever was his title, were assigned the most solemn of the religious offices entrusted to the body. In Egypt the population is supposed to have been divided into three or four castes, at the head of which was the sacerdotal, or priests. This division, however, was not very strictly observed, as the son did not invariably follow the profession of the father. That of the priest appears most honourable, and two principal classes of priests were in existence at the earliest periods—the *hont*, or prophets, and the *ab*, or inferior priests. The first were attached to the worship of all the deities of Egypt; and in the greater cities there was *hont api*, high prophet, or priest, who presided over the others; at Thebes there were as many as four prophets of Ammon. Their duties appear to have comprised the general cultus of the deity. They also interpreted the oracles of the temples. Besides the prophets of the gods, others were attached to the worship of the king, and to various offices connected with the administration of the temples. The class of priests called *ab*, or 'pure,' were inferior, and were also attached to the principal deities and to the personal worship of the monarch. They were required to be scrupulously neat and clean, entirely shaven, and ascetic in their diet, bathing and fasting frequently. The priesthood of India belongs to the first caste, or that of the Brahmans, exclusively (see Caste, India). But, as the proper performance of such functions requires, even in a Brahman, the knowledge of the sacred texts to be recited at a sacrifice, and of the complicated ceremonial of which the sacrificial acts consist, none but a Brahman learned in one or more Vedas, and versed in the works treating of the ritual, possesses, according to the ancient law, the qualification of a priest. See also Buddhism, Lamaism.

In sacred history the patriarchal period furnishes an example of the family priesthood; while in Melchizedec, king of Salem, we find the union of the royal with the priestly character. In the Mosaic law the whole theory of the priesthood, as a sacrificial and mediatorial office, is fully developed. The priest of the Mosaic law stands in the position of a mediator between God and the people; and, even if the sacrifices which he offered be regarded as but typical and prospective in their moral efficacy, the priest must be considered as administering them with full authority in all that regards their legal value. The Mosaic priesthood was the inheritance of the family of Aaron, of the tribe of Levi (q.v.). It consisted of a High-priest (q.v.), and of inferior ministers, distributed into twenty-four classes. The age for admission to the priesthood is nowhere expressly fixed; but, from

2 Chronicles, xxxi. 17, it would seem that the minimum age was twenty. In the service of the temple the priests were divided into twenty-four classes, each of which was subject to a chief priest, and served, each company for a week, following each other in rotation. Their duties in the temple consisted in preparing, slaying, and offering victims, in preparing the show-bread, burning the incense, and tending the lights of the sanctuary. Outside they were employed in instructing the people, attending to the daily offerings, enforcing the laws regarding legal uncleanness, &c. For their maintenance were set aside certain offerings (see FIRST-FRUITS) and other gifts. They wore a distinguishing dress, the chief characteristics of which were a white tunic, an embroidered cincture, and a turban-shaped head-dress. The Jewish priesthood may be said to have practically ceased with the destruction of the temple.

In the Christian dispensation the name primitively given to the public ministers of religion was *presbyteros*, of which the English name 'priest' is but a form derived through the old French or Norman *prestre*. The name given in classical Greek to the sacrificing priests of the pagan religion, Gr. *hiereus*, Lat. *sacerdos*, is not found in the New Testament explicitly applied to ministers of the Christian ministry; but very early in ecclesiastical use it appears as an ordinary designation; and with all those bodies of Christians—Roman Catholics, Greeks, Syrians, and other Orientals—who regard the eucharist as a sacrifice (see LITURGY) the two names were applied indiscriminately. The priesthood of the Christian church is one of the grades of the hierarchy, second in order only to that of bishop, with which order the priesthood has many functions in common. The priest is regarded as the ordinary minister of the eucharist, whether as a sacrament or as a sacrifice; of baptism, penance, and extreme unction; and although the contracting parties are held in the modern schools to be themselves the ministers of marriage, the priest is regarded by all schools of Roman divines as at least the normal and official witness of its celebration. The priest is also officially charged with the instruction of the people and the direction of their spiritual concerns, and by long-established use special districts, called parishes, are assigned to priests, within which they are entrusted with the care and supervision of the spiritual wants of all the inhabitants. The holy order of priesthood can only be conferred by a bishop, and he is ordinarily assisted by two or more priests, who, in common with the bishop, impose hands on the candidate. The rest of the ceremonial of ordination consists in investing the candidate with the sacred instruments and ornaments of his order, anointing his hands, and reciting certain prayers significative of the gifts and the duties of the office. The distinguishing vestment of the celebrant priest in the mass is the *Chasuble* (q.v.). In Catholic countries priests wear even in public a distinctive dress, in most respects common to them with the other orders of Clergy (q.v.). In the Latin Church priests are bound to a life of celibacy. In the Greek and oriental churches married men may be advanced to the priesthood; but no one is permitted to marry after ordination, nor is a married priest permitted to marry a second time, should his wife die.

In the Church of England, and other Reformed Episcopal Churches, the term priest is retained as the designation of the second order of clergy, whose special office it is (1) to celebrate the Sacrament of the Lord's Supper; (2) to pronounce the forms of Absolution in the Morning and Evening Prayer, in the Communion Service, and in the Office for the Visitation of the Sick; and (3) to preach, though this last office is, by special license, sometimes extended to deacons. See DEACON, ORDERS (HOLY).

Priestley, JOSEPH, son of a cloth-dresser, was born at Fieldhead, near Leeds, 13th March 1733. For some time he was obliged to abandon school studies, owing to weak health, and betook himself to mercantile pursuits, but with returning strength his literary studies were resumed at a dissenting academy at Daventry (founded by Dr Doddridge). Though his father and family were strong Calvinists, young Priestley, during his residence at the academy, felt called on to renounce nearly all the theological and metaphysical opinions of his youth. 'I came,' he says, 'to embrace what is called the heterodox side of every question.' In 1755 he became minister to a small congregation at Needham Market, in Suffolk. While here he composed his work against the doctrine of Christ's death being a sacrifice or satisfaction for sin, entitled *The Scripture Doctrine of Remission*. In this he taught that the Bible is indeed a divine revelation, made from God to man through Christ, himself a man and no more, nor claiming to be more, and rejected the doctrines of the Trinity and the Atonement. In 1758 he quitted Needham for Nantwich; and in 1761 he removed, as teacher of languages and belles-lettres, to an academy at Warrington; and here his literary career may be said first fairly to have begun. A visit to London led to his making the acquaintance of Franklin, who supplied him with books which enabled him to write his *History and Present State of Electricity*, published in 1767. It was followed by a work on *Vision, Light, and Colours*. In 1762 he published his *Theory of Language and Universal Grammar*. In 1764 he was made LL.D. of Edinburgh, and F.R.S. in 1766. In the following year he removed to Leeds, having been appointed minister of the Mill Hill dissenting chapel there. The fact of a brewery being beside his dwelling gave a new direction to his energetic and versatile mind; he began to study chemistry. In 1773 he was appointed literary companion to Lord Shelburne, and accompanied the earl on a continental tour in 1774. Having been told by certain Parisian savants that he was the only man of understanding they had ever known who believed in Christianity, he wrote, in reply, the *Letters to a Philosophical Unbeliever*, and various other works, containing criticisms on the doctrines of Hume and others. But, while laughed at in Paris as a believer, at home he was branded as an atheist. To escape the odium arising from the latter imputation, he published, in 1777, his *Disquisition relating to Matter and Spirit*, in which, partly materialising spirit and partly spiritualising matter, he holds that our hopes of resurrection must rest solely on the truth of the Christian revelation, and that on science they have no foundation whatever. On leaving Lord Shelburne, he became minister of a dissenting chapel at Birmingham. The publication, in 1786, of his *History of Early Opinions concerning Jesus Christ* occasioned the renewal of a controversy, which had begun in 1778, between him and Dr Horsley, concerning the doctrines of Free-will, Materialism, and Unitarianism. His reply to Burke's *Reflections on the French Revolution* led to his being made a citizen of the French Republic; and this led to a mob on one occasion breaking into his house and destroying all its contents, books, manuscripts, scientific instruments, &c. A brother-in-law, however, about this time left him £10,000, with an annuity of £200. In 1791 he was elected to a charge at Hackney; but his honestly-avowed opinions had made him unpopular, and he (1794) removed to America, where he was heartily received. He died at Northumberland, Pennsylvania, 6th February 1804, expressing (though

he agreed that he should be called a materialist) his confidence in immortality. He was a man of irreproachable character, serene of temper, fearless in searching after and confessing the truth. His services to chemistry are summed up at Vol. III. p. 147 (and see OXYGEN); recent research fully justifies Priestley's title to be called the father of pneumatic chemistry; Thorpe, at the British Association, 1890 (see *Nature*, xlii. 449), not merely defended the priority of his discovery of oxygen (1774) and of the composition of water (1781), but denied Lavoisier's claim to be considered an independent discoverer. See J. T. Rutt's edition of Priestley's *Works* (25 vols. 1832), including Autobiographical Memoir; and Martineau's *Essays, Reviews, and Addresses* (vol. i. 1891).

Priest's Hole. See SECRET CHAMBER.

Priluki, a town of Russia, 87 miles E. by N. of Kieff, with trade in corn and cattle. Pop. 15,231, mostly engaged in the cultivation of tobacco.

Prim, JUAN, Spanish general, was born at Reus, 6th December 1814, and rapidly rose to be a colonel, and so distinguished himself in war and statesmanship as to be made general, marshal, and marquis. As progressist he opposed Espartero. Failing in an insurrectionary attempt in 1866, he had to flee to England and Brussels, but here he guided the movement that in 1868 overthrew Isabella. He was war minister under Serrano, but soon became virtually dictator. He secured the election of an Italian prince, Amadeo, as king (in order, as was thought, that the king might be under the minister's control), and was thereupon shot by an assassin as he left the Cortes, 28th December 1870. He died on the 30th.

Prima Donna (Ital.), the first female singer in an opera.

Primage, a charge (over and above the freight) paid by the shipper or consigner of goods for loading the same, to the master and sailors of a ship, or to the owner or freighter.

Primary Colours. See COLOUR.

Primary Rocks. See PALÆOZOIC.

Primate (Lat. *primas*), anciently a bishop holding a position of pre-eminence. Thus the bishop of Rome was called primate of the whole church. In modern times the title belongs only to such sees as had formerly the dignity of vicar of the holy see annexed—Armagh, Arles and Lyons, Mainz, Toledo, Pisa and Salerno, &c. But none of these possess any special primatial jurisdiction. For the primates in the Church of England, see the article ARCHBISHOP. The name *primus* is applied in the Scottish Episcopal Church to the presiding bishop. He is chosen by the bishops out of their own number, without their being bound to give effect to seniority of consecration or precedency of diocese.

Primates, the name given by Linnæus in his system to the first order of Mammals (q.v.), which he placed first (whence the name, Lat. *primus*, 'first') because he ranked man amongst them.

Prime, the first of the 'lesser hours' of the Roman Breviary (q.v.).

Prime-minister. See TREASURY, CABINET.

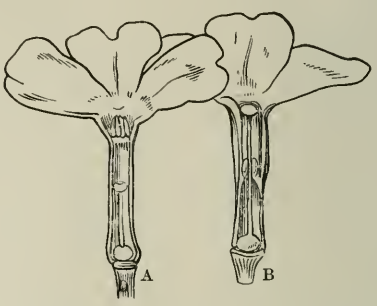
Primero, or PRIME, a game at cards popular in England in the 16th century, but now obsolete. The same or a very similar game was played in Italy under the name *primiera*, and in France under the names *prime*, *ambigu*, &c. Primero belonged to the family of games of which the old post and pair and the more modern brag and poker are members.

Primitive Methodists. See METHODISTS.

Primogeniture is the rule of law under which the eldest son of the family succeeds to the father's real estate in preference to, and in absolute exclusion of, the younger sons and all the sisters. See ENTAIL, FAMILY, FEUDALISM, FIRST-BORN, LAND LAWS, SUCCESSION; and the valuable monograph on *Primogeniture* (1895) by Evelyn Cecil.

Primordial Zone, a name applied by Barrande to the group of strata which in Bohemia underlies the Silurian rocks, and is therefore on the horizon of the Cambrian system.

Primrose (*Primula*), a genus of plants of the natural order Primulaceæ, having a bell-shaped or tubular five-toothed calyx, a salver-shaped corolla with five segments, five stamens, a globose germen containing many ovules, and a many-seeded capsule opening by five valves, and generally with ten teeth at the apex. The dimorphism of the stamens and pistil of primrose, illustrated in the accompanying figure, is not uncommon in other species of the genus, and has given rise to the terms *thrum-eyed* (A) and *pin-eyed* (B) in the language of florists in



Primroses; short (A) and long styled (B).

describing varieties of the Auricula and Polyanthus. The distinction is of some practical importance in so far as fertilisation of the individual flowers is affected by the relative positions of the respective organs. The species are all herbaceous perennials, generally having only radical leaves; and the flowers in a simple umbel, more rarely with scapes bearing solitary flowers. Almost all of them are natives of Europe and the north of Asia. Some of them are among the finest ornaments of our groves and meadows; some are found in mountainous regions. Their fine colours and soft delicate beauty have led to the cultivation of some of

Common Primrose (*Primula vulgaris*).

them as garden flowers, probably from the very beginning of floriculture. The name Primrose (Fr. *Primevère*, Lat. *Primula*) is derived from the Latin *primus*, 'first,' and refers to the early appearance of the flowers of some of the most common

species in spring. The Common Primrose (*P. vulgaris*), abundant in woods, hedgebanks, and pastures in Britain and in most parts of Europe, has obovate-oblong, wrinkled leaves, and single-flowered scapes; the flowers about an inch broad, yellowish white. This is the plant to which the English name primrose specially belongs. Akin to it is the Cowslip (q.v.), or Paigle (*P. veris*), and perhaps still more nearly related is the Oxlip (*P. elatior*), apparently wild in some parts of England, particularly in the eastern counties, but supposed by some botanists to be intermediate between the common primrose and the cowslip, which they therefore regard as extreme forms of one species. The Polyanthus (q.v.) is a cultivated variety of the cowslip. The Auricula (q.v.; *P. auricula*), an Alpine species, is a favourite garden flower. The Bird's-eye Primrose (*P. farinosa*) and the Scottish Primrose (*P. scotica*) are both flowers of exquisite beauty, found in the northern parts of Britain, the latter chiefly on the coasts of Sutherland, Caithness, and the Orkney Islands. The Alps and the Himalaya Mountains produce several species. The Chinese Primrose (*P. sinensis*) has for more than fifty years been very common in Britain, not only as a greenhouse but a window plant. It produces compound umbels of very numerous lilac, red, or white flowers, which are displayed in autumn, winter, and spring. Two varieties occur in the eastern states of the American Union—the Bird's-eye Primrose (*P. farinosa*) and *P. mistassinica*, both rare—and several varieties in the western states, the most conspicuous being *P. parryi*, with large purple flowers, which grows on the Rocky Mountains.

Primrose League. This political organisation was founded November 17, 1883, by Lord Randolph Churchill, Sir John Gorst, Sir Alfred Slade, and Sir H. Drummond Wolff. The name was chosen in reference to the fact that the primrose was Lord Beaconsfield's favourite flower (a fact by some unkindly disputed; cf. *Notes and Queries* for 1888, pp. 146, 416); and the fivefold petal of that flower is taken to indicate the five principal divisions of the British empire in Europe, Asia, Africa, America, and Australia. This strictly Conservative society, by the moderation and even liberality of its professions, by its enlistment and organisation of women, by its distribution of titles and badges, and by its choice of an emblem dear to all and accessible to all, has attained an enormous growth and great political influence. It was originally intended to admit men only, banded in companies of about 100 to act as missionaries of the league; and the effect of admitting women may be gathered from the fact that the number of members rose from 957 in 1884 to 237,283 in 1886. The numbers as given by the society in 1891 were: habitations, 2126, and knights, dames, and associates enrolled as members, 963,943. The first grand-master of the Primrose League was the Marquis of Salisbury, K.G. The head office is at 64 Victoria Street, Westminster. In July 1890 the first branch in Canada was established at Winnipeg. See an article by Sir A. Borthwick in the *Nineteenth Century* for July 1886.

Primulaceæ, a natural order of exogenous plants, containing more than 200 known species, mostly natives of temperate and cold regions. They are all herbaceous, or scarcely half-shrubby, with leaves generally all radical, and no stipules. The calyx is generally five-cleft, inferior or half-superior, regular, persistent; the corolla, with the limb divided into as many segments as the calyx, rarely wanting; the stamens inserted on the corolla, one opposite to each of its lobes; the ovary one-celled, the style solitary, the stigma capitate; the capsule with a central placenta and many seeds.—Many of the Primulaceæ have flowers of much

Flowers of a few of the Primulaceæ:
a, Primula sikkimensis; b, P. obconica; c, P. sieboldii; d, common primrose (*P. vulgaris*); *e,* cowslip (*P. veris*).

beauty, and some are very fragrant, as the Primrose, Cowslip, Auricula, Pimpernel, &c.

Primum Mobile. See PTOLEMY.

Prince (Lat. *princeps*), an epithet which was originally applied to the *princeps senatûs* of the Roman state, and afterwards became a title of dignity. It was adopted by Augustus and his successors; hence the word was afterwards applied to persons enjoying kingly power, more especially the rulers of small states, either sovereign or dependent. The title is now very generally applied to the sons of kings and emperors and persons of the blood-royal, sometimes with a territorial title (Prince of Wales, Prince of Orange), or with an addition, 'crown prince,' 'prince imperial,' &c. In various parts of continental Europe the title prince is borne by families of eminent rank but not possessed of sovereignty. Practically in Britain the term prince is restricted to members of the royal family (see PRECEDENCE). The eldest son of the reigning sovereign is by a special patent created Prince of Wales (see WALES, PRINCE OF). In France, under the old regime, dukes took precedence of princes; and many dukes had princedoms as minor titles. Napoleon put his new-created princes above dukes. In Italy princes rank after dukes, sons of dukes being called princes. In Germany the ambiguity of applying the same title to the members of royal houses and princely families, not sovereign, is avoided, the former being styled 'Prinz,' the latter 'Fürst.' The German Fürst takes rank below the Duke (Herzog). Most of the counts who had a seat in the old German Diet were elevated to the dignity of Prince on their acquiescence in the dismemberment of the German empire (see GERMANY, Vol. V. p. 177). In a more general acceptation the term prince is often used for a sovereign or the ruler of a state.

Prince Edward Island is a province of the Dominion of Canada, having entered the confederation in 1873. It is situated in the Gulf of St Lawrence, and is separated from New Brunswick and Nova Scotia by Northumberland Strait. The greatest length of the island is 130 miles; its breadth varies from 4 to 34 miles, and it has an

area of 2133 sq. m.—i.e. about 1,365,400 acres, nearly all of which are occupied. Population in 1891 numbered 109,088, or 52 persons to the square mile. Although discovered by the Cabots, no claim was made to it by the British on that account. Possession was assumed by the French, but little was done towards its settlement until 1715, when its fertility attracted some Acadians from Cape Breton. It was finally ceded to Great Britain in 1763. In the first instance it formed part of Nova Scotia, but in 1768 was made a separate province. The pop. in 1763 was 4000; but about that time an emigration set in to the mainland, and the Acadians were expelled, so that in 1768 it had been reduced to about 1300 (see ACADIA). Until 1799 it was called St John's Island, but its name was then changed to Prince Edward Island, in compliment to the Duke of Kent, who paid it a visit in that year. Prior to 1875 most of the land was the property of absentee proprietors, and for many years the land question was a source of difficulty. The local government, however, passed a measure in 1875 giving them powers to buy out the landlords, and to sell the land to the tenants or others on easy terms of repayment. Out of the 843,981 acres acquired by the government in that way, all but 97,162 acres had been disposed of up to 1889; and the payments are being met in a satisfactory manner, the arrears being very trifling. By this legislation a fruitful source of irritation was removed, and the agricultural industry—the principal one in the province—placed on a more satisfactory footing.

Seen from the water, the appearance of the island is exceedingly prepossessing. The surface is undulating, but never exceeds 500 feet; the soil is very fertile, consisting generally of a light reddish loam, and occasionally of a stiffer clay, resting in some places on red sandstone, although in other localities it seems to be entirely alluvial. All kinds of cereals, roots, and vegetables are raised. Oats and potatoes from the island enjoy a special reputation, and the same thing may be said of its sheep and horses. A natural manure, called mussel mud, and made of decayed oyster, clam, and mussel shells, is found on the coasts of the island. It is largely used by the farmers, and is said to be a most valuable fertiliser. Although coal is known to exist, it is not worked, owing to the depth at which it is found and the cheapness at which it can be purchased from Nova Scotia. There are apparently no other minerals on the island. The climate is healthy, being milder than that of the mainland, and freer from fogs. Winter is long and tedious, but the summer months are pleasant and enjoyable. Prince Edward Island is without doubt the best fishing station in the Gulf of St Lawrence, but the habits and feelings of the inhabitants are so decidedly agricultural that the fisheries have not received from them the attention they deserve. They consist chiefly of mackerel, lobsters, herring, cod, hake, and oysters; while salmon, bass, shad, halibut, and trout are caught in limited quantities. In the last years of the past century the value of the fisheries had reached $980,000 a year. The annual value of the oyster-fishery exceeds $120,000; and this industry is still capable of vast development. Lobsters are exported to the extent of about 920,000 lb. annually, of the value of $120,000. Of the 718,000 acres of cultivated land, 540,000 are under crop, 178,000 are pasture, and 4000 are gardens and orchards. The conditions are also favourable for the breeding and rearing of live stock, of which large numbers are annually exported to other parts of Canada and the eastern states of the American Union.

The coast-line is a succession of bays and projecting headlands; the largest bays are Egmont, Hillsborough, and Cardigan, which by penetrating into the land from opposite directions form narrow isthmuses, dividing the island into three distinct peninsulas. Charlottetown is the capital, and has a pop. of 13,000. Other principal towns are Summerside (3000), Georgetown, and Souris. The rivers are naturally short, but the province is well watered. Manufactures are not carried on to any large extent, and chiefly for local purposes. Shipbuilding was an important industry previous to the substitution of iron and steel for wooden vessels.

The exports for 1890 were valued at $875,964, divided as follows: Produce of the mine, $20; forest, $7575; fisheries, $187,743; agriculture, $664,638; manufactures, $14,871; and miscellaneous, $1117. Imports were valued at $581,177. There is a railway, built and worked by the Dominion government, running from one end of the island to the other. The island is connected by telegraph with the mainland, and there is daily steam communication between the two, although it is occasionally interrupted during the winter. In 1891 the people were urging the construction of a tunnel under the Northumberland Strait, for the purpose of establishing communication with the mainland all the year round. The Dominion government directed an estimate of the cost to be prepared. The tunnel would be some 7 miles long. According to the census of 1891, the settlers were largely of English, Irish, and Scotch descent, and French, Germans, and Scandinavians. The principal religious denominations were: Roman Catholics, 47,115; Presbyterians, 33,835; Methodists, 13,485; Church of England, 7192. The Bishop of Nova Scotia exercises episcopal authority over the island, and the Roman Catholics have one diocese, that of Charlottetown. Free education has prevailed since 1853. In 1898 the district schools numbered about 467. There are also grammar-schools, private schools, a normal and a model school, and two colleges—the Prince of Wales (Protestant) and St Dunstan's (Roman Catholic). The government of the island is administered by a lieutenant-governor, appointed by the governor-in-council, and paid out of federal funds. The legislative council consists of thirteen members, and the assembly of thirty members, the latter being elected for four years. In the Dominion senate the province is represented by four members, and in the House of Commons by six.

Princeites, a name given to the Agapemoné (q.v.) from the founder.

Prince of Wales. See WALES, PRINCE OF.

Prince of Wales Island. See PENANG.

Prince Rupert's Drops. See ANNEALING.

Princes Islands (anc. *Demonnesoi*), a beautiful group of nine islets near the eastern end of the Sea of Marmora, about 10 miles SE. of Constantinople, the largest being called Prinkipo. They are a favourite summer-resort of the Constantinople Greeks, and in old times were frequently a place of exile for those in disfavour at the Byzantine court. See Schlumberger, *Les Îles des Princes* (1884); S. S. Cox, *The Isles of the Princes* (New York, 1888).

Prince's Metal, a name, derived from Prince Rupert, given to an alloy of copper and zinc, in which the proportion of zinc is greater than in brass.

Princeton, (1) capital of Gibson county, Indiana, 161 miles by rail E. of St Louis. It has woollen manufactures. Pop. (1880) 2566; (1890) 3076.—(2) A pleasant borough of New Jersey, 50 miles by rail SW. of New York and 47 NE. of Philadelphia. Pop. 3409. On January 3, 1777, it

was the scene of a battle between the British under Colonel Mawhood and the Americans under Washington, in which the former were defeated; here the Continental Congress sat in 1783; and from Princeton Washington dated his farewell address to the army. Princeton, however, is chiefly celebrated as the seat of the College of New Jersey, popularly known as Princeton College, which, founded by charter in 1746, under the auspices of the Presbyterian Synod of New York, held its first commencement under its second charter at Newark in 1748. Liberal subscriptions were obtained both in America and in Britain, the Bishop of Durham being among the contributors, and the General Assembly of the Church of Scotland ordering a national collection. In 1756 the college was transferred to Princeton, on the erection of a hall named Nassau Hall in honour of William III. Within it hangs a portrait of Washington. The College of New Jersey has had several distinguished Presbyterian divines for its presidents, as Jonathan Edwards and Dr James M'Cosh. Since the civil war benefactions have poured in upon the college; during the twenty years of Dr M'Cosh's presidency these exceeded $3,000,000. Post-graduate courses have been introduced, and the staff of instructors raised to about eighty; the number of students is now about 1100. Among its graduates have been James Madison, fourth president of the United States, and many very eminent men. The theological seminary, founded in 1812, the oldest and largest of the Presbyterian Church in America, has nearly 200 students. With the Princeton theological school is associated the fame of the *Biblical Repertory and Princeton Review*, founded in 1825, and edited till 1872 by Dr Hodge (q.v.). The *Review* has since, however, been united with the *Presbyterian Quarterly*, which is published in New York. In 1874 a school of science was opened; and the college possesses five museums, four laboratories, two observatories, and libraries with 137,000 volumes. See *Harper's Magazine*, November 1890.

Principal. See AGENT and SURETY; also ACCESSARY.

Pringle, THOMAS, minor poet, was born at Blaiklaw (near Kelso), Roxburghshire, 5th January 1789. Lame from childhood, dyspeptic, devout, he went at seventeen to Edinburgh University, and found bread if not contentment of mind as clerk in the Scottish Public Records Office. He took to writing at an early age, and, besides other literary schemes and ventures, started the *Edinburgh Monthly Magazine*, the parent of *Blackwood*, in which his own most important article was on the Gypsies, from notes supplied by Scott. In 1820 he set sail with a party of twenty-four emigrants of his father's family for Cape Colony. He travelled into the interior with the party, and had his heart stirred within him to see the inhumanity practised towards the natives by English and Dutch residents alike. For three years he lived at Capetown as librarian of the government library at a salary of £75 a year. He started the *South African Journal*, and fought a brave fight for the freedom of the press. But he was bullied by the tyrannical and petty-minded governor of the day, Lord Charles Somerset, his schemes crushed, and himself reduced to poverty. He returned to London in 1826, and became secretary of the Anti-Slavery Society. He died in London, 5th December 1834. His *Ephemerides* (1828) was a collection of graceful verse. Those poems that related to South Africa—the best 'Afar in the Desert'—were reprinted in the volume of *African Sketches* (1834), a series of glowing sketches of South African scenery. Pringle's *Poetical Works* were edited, with a florid eulogium, rather than a life, by Leitch Ritchie (1839).

Printing is the art of taking, by pressure, prints or copies in reverse of an original design of a suitable character, coated with a pigment or ink. The word has a very wide application, and is used, for instance, in connection with such different processes as photographic 'printing,' in which no pressure is required, and calico-printing. A definition based upon pressure alone would bring within the category of 'prints' such operations as moulding, stamping, and embossing. The word has, however, acquired conventional limitations of meaning, and is now applied usually to the three methods of copperplate printing (see ENGRAVING), Lithography (q.v.), and letterpress printing. The first two being already described, the present article will be confined to a description of the latter.

There is no doubt the Chinese practised printing in some senses of the word many centuries before it was known in Europe, as has been noticed at CHINA, Vol. III. p. 196. The method commonly used down to the present time is one originally adopted by Foong Taou in the 10th century. A piece of pear-tree wood is cut up into boards of about half an inch thick, and these into blocks large enough for two pages of the book to be printed. The blocks are planed, squared, and sized or varnished. The design to be engraved is drawn or written on thin transparent paper, and transferred to the surface of the block by rubbing. The engraver next cuts away the field, leaving the transferred letters in high relief. Labour being cheap, a block of this kind can be cut at about the same expense as it could be set up in movable metal types, and it needs no proof-reading or correction. For printing no press is used, the block being adjusted on a table, before which the printer stands, having a bowl of fluid ink on one side and a pile of paper on the other. In his right hand he has two flat-faced brushes, fixed on the opposite ends of the same handle. One brush is dipped into the ink and swept over the face of the block, on which a sheet of paper is placed; the back of the paper is then swept lightly but firmly with the dry brush at the other end of the handle. This is all that is needed to fasten the ink on the paper—which is soft, thin, pliable, and a quick absorbent of fluid ink. Printing from movable types was, according to Professor Douglas, probably practised in China as early as the 12th or 13th century, as there are Corean books printed from movable clay or wooden types in 1317. But the Chinese still prefer block-printing; and printing from metal types in China is mainly practised for circulating the Bible and for newspapers, according to methods invented by Europeans. About 6000 Chinese characters suffice for a missionary printing-office; but for magazine work about 10,000 are necessary. For the baseless tradition that Marco Polo brought the knowledge of block-printing thence, see POLO.

The art of printing by the use of movable types was invented in Europe about the middle of the 15th century; but no more definite statement concerning its origin can be made with confidence. The name of the country in which the invention took place, the name of the inventor, the year of the invention are, up to the present time, matters of dispute. Modern researches have completely disposed of as a mere legend the widespread belief that the invention of movable metal types, cast in a mould from a matrix—the essential principle of typography—was preceded by or was the outcome of the use of wooden types, which it was formerly thought formed the link between the block-books common in the early part of the 15th century (see WOOD-ENGRAVING)

and the earliest letterpress prints. Equally baseless is the belief that the first metal types were cut instead of being cast. The evidence on these two points is too minute and technical to be adduced here.

The controversy as to the invention of printing has lasted nearly four centuries, and it has unhappily been carried on with a vehemence and bitterness which perhaps no other controversy, not a religious one, has ever excited. Up to 1499 it was universally believed that typography was invented at Strasburg by Gutenberg (q.v.), who afterwards set up a press at Mainz, from which emanated the magnificent Latin Bible, for many years called the Mazarin Bible, owing to a copy having been discovered by De Bure in Cardinal Mazarin's library at Paris. Gutenberg's name does not appear in a single production of his press, and none of his associates mention his name as the inventor of printing. In 1499 there was published at Cologne the *Cronica van der hilliger Stat van Coellen*, since known as the *Cologne Chronicle*, in which one chapter is devoted to the origin of printing. The chronicler declares that the art was discovered first of all in Germany, at Mainz on the Rhine; that it took place about 1440, but that, although it was discovered at Mainz, the first 'prefiguration' was in Holland, in the form of the *Donatuses* which were printed before that time; that the circumstances of the origin had been communicated to the chronicler by Ulric Zell, a contemporary printer at Cologne. To these statements may be attributed the commencement of the controversy ever since carried on. In 1588 Adriaen de Jonghe ('Hadrianus Junius'), in his *Batavia*, printed in the Plantin office at Antwerp, gave the first circumstantial account of the alleged Dutch invention, which, he said, he had heard from old and trustworthy people. This was, it will be noticed, about a century and a half after the invention. Junius stated that in 1440 'Lourens Janszoon,' surnamed Coster (q.v.), lived at Haarlem; that he one day took a walk in the Hout, and cut letters on the bark of a beech-tree; that he printed these letters on paper for the amusement of children; that he invented a suitable printing-ink, and afterwards began to print whole sheets, with pictures; subsequently he used leaden letters, and then tin ones. Among his workmen was one Johannes—the surname was not given by Junius—who in 1441 stole the types and fled to Mainz, where he opened a workshop, and in 1442 published, with Coster's types, the *Doctrinale* of A. Gallus and the *Tractatus* of P. Hispanus. From this date, as already stated, the question whether printing was 'invented' in Holland or in Germany has been fiercely debated, and scores of books have been written upon it. The titles of these are given in Bigmore and Wyman's *Bibliography of Printing* (3 vols. Lond. 1880–86). The controversy was renewed with much vigour, and unfortunately with much acrimony, in 1870; and it has since been maintained, the balance of evidence, or rather of probability—for of evidence there is an extraordinary lack—oscillating from time to time to one side and then to the other. In 1870 the 'Costerians' included nearly all the leading bibliographers and typographical historians. An eminent Dutch investigator, Dr van der Linde, published a series of articles, since translated into English (Lond. 1871) under the title of *The Coster Legend*. The purport of the book was that the documents brought forward to support the claims of Coster were false, and that the arguments in his favour were devoid of any historical or bibliographical support. Van der Linde showed further that several of the documents on which the Costerians relied were actually frauds and forgeries. This exposure for a time completely routed the supporters of the Dutch claims. In 1878 the same author produced a companion volume, *Gutenberg—Geschichte und Erdichtung aus den Quellen nachgewiesen*, but there was little new in it. Mr Hessels of Cambridge, a native of Haarlem, next took up the subject on original lines, and issued the work *Gutenberg: Was he the Inventor of Printing?* (Lond. 1882). He maintained that Van der Linde was untrustworthy, and that his book presented a more complete chaos of error on the subject than its predecessors. Mr Hessels spent several years in examining in Germany all the documents extant connected with the history of Gutenberg, and exposed a number of falsifications and forgeries which had passed current. Space will not here suffice to recapitulate his discoveries; his book is indispensable to any one desiring an accurate knowledge of the subject. The result of his researches was more negative than positive. He said that he had not found anything which enabled him to answer in the affirmative or in the negative the question, Was Gutenberg the inventor of printing? Of the three principal documents relied upon by his supporters one is lost entirely, and the other two are only transcripts. Even if we accept these transcripts, he says, they point to Gutenberg only as a printer, but not as the inventor of printing. In 1886 Dr van der Linde wrote from the German side another book, *Geschichte der Erfindung der Buchdruckerkunst*. It was produced in magnificent style at the cost of the German government, but it added to our knowledge of the contention nothing of importance. Mr Hessels has since continued his investigations, and the result is indicated in the title of his book, issued in 1887, *Haarlem the Birthplace of Printing, not Mainz*. This important work virtually takes us back to 1499, when the *Cologne Chronicle* declared that the first idea of printing was found in Holland. The case now stands thus: very crude and clumsy specimens of printing—some of which have been quite recently discovered—are generally allowed to be 'Costeriana.' On the other hand, there is the magnificent Bible and Psalter undeniably printed by Gutenberg and his associates. It is difficult to believe that the masterpiece preceded the rude essays. It is more reasonable to conclude that, anterior to Gutenberg's press, there was a rude school of typography in existence. Important discoveries may at any time take place. The contents of many old continental libraries have even up to the present not been adequately examined. Possibly within some ancient bindings there exist at the present moment prints that would settle for all futurity the controversy which has raged for four centuries as to the 'origines typographici.'

It has been mentioned at GUTENBERG that after Fust had obtained possession by action at law of Gutenberg's office, and while he was carrying it on as a printing concern, Gutenberg, by the assistance of another capitalist, set up a second office. With two rival establishments in existence, it was impossible to keep secret the processes of printing. In 1462 the city of Mainz was sacked, and the catastrophe dissolved engagements between employers and employed, and caused many of the latter to migrate to other countries, taking with them, of course, their knowledge of the art. Printing spread with marvellous rapidity, considering the means of transport and of communication then in existence. For instance, before 1500 there were 16 master printers at Strasburg, 22 at Cologne, 17 at Nuremberg, 20 at Augsburg. By the end of the 15th century the business was carried on in about 60 places in central and northern Europe, 21 in the Netherlands, 32 in Italy, 31 in France, 22 in Spain and Portugal

(Henry Cotton's *Typographical Gazetteer*, 3d ed. Oxford, 1852–66).

Printing was brought to England in 1476 or 1477 by William Caxton (q.v.), who set up his office within the 'precincts' of Westminster Abbey—but not within the sacred building itself, as often erroneously stated. See William Blades's *Biography and Typography of William Caxton* (2d ed. Lond. 1882). The first hundred years of the history of printing in England was a period of great activity. In 1478 printing was done at Oxford by Theo. Rood; in 1480 at St Albans by an unidentified printer now called 'the Schoolmaster;' in the same year in the city of London by Letton; in 1521 at Cambridge by Siberch. When the art had spread throughout the country, when education became more common, and men began to read about the questions and events of the day, it began to be seen by the authorities and rulers that a mighty power for good or evil had arisen in the land. Then it was deemed necessary to regulate the press. In 1530 censorship was established in England. It ushered in a period of lamentable decadence in the quality and quantity of the printing done. Printers were cruelly punished, especially during the existence of the unconstitutional Star-chamber (q.v.). Oppressed, abused, and often imprisoned, printers lost all enterprise and all social position. For many years there were no good printers at all. Censorship was abandoned in 1694. Then began a period of revival, greatly aided by the improvements in type-founding in the middle of the 18th century, and the prevalence of the 'Bibliomania' towards its close. The 19th century has been one of marvellous development, following the invention in 1814 of the steam printing-press.

It is believed that printing was introduced into Scotland in 1507. A patent has been discovered, of King James IV., which shows that a printing-press was established at Edinburgh during the year named. This patent was granted to two burgesses of the city of Edinburgh—Walter Chepman, a capitalist and speculator, and Andrew Myllar, a bookseller who had learned in France the art of printing. The 'prent and expert men' to use the press came from France. The office was in the Southgait, now the Cowgate. As early as 1508 several small publications were issued. After these came the great work for which the press was ostensibly established—the 'Aberdeen Breviary,' in two volumes, forming 1554 pages of small type. It was intended to become the standard Scottish service-book. Myllar was probably dead when it was completed, and with its publication Chepman's connection with typography came to an end. For many years subsequently all works of Scottish authors were printed in France. The next printer was Thomas Davidson, a practical man who in 1541 was chosen to print acts of the parliament of James V., which placed him in the position of king's printer. It is not necessary to catalogue the names or the works of his immediate successors. Up to 1600 the average workmanship of the Scottish printers was about as bad in quality as that of their later successors has been distinguished for its beauty, excellence, and accuracy. This is not the only noteworthy feature of early Scottish typography. The printers were astonishingly few in number; during 150 years after the introduction of the art there were only about a dozen master printers who were natives. During the first hundred years only twenty-five different works are known to have been printed in Scotland. See R. Dickson and J. P. Edmond, *Annals of Scottish Printing from the Introduction of the Art to the Beginning of the 17th Century* (4to, Cambridge, 1890)—a most exhaustive and trustworthy book.

The first printing-press set up in America was introduced by the viceroy of Mexico, Antonio de Mendoza, and the first book printed by it in the New World was *La Escala de S. Juan Climaco* (1536). The earliest press in the British-American colonies was brought over for Harvard College in 1638. The *Bay Psalm Book* (1640) was its first important work (see Eliot, John); but in 1639 it printed the *Freeman's Oath* and an almanac. The first press in Philadelphia was set up in 1685, in New York in 1693. See I. Thomas, *History of Printing in America* (2d ed. Albany, 1874).

The practical art of letterpress printing consists essentially in coating certain relief surfaces with printing-ink, and then transferring that ink to the fabric, such as paper. The relief surface may be a forme of movable types or an engraved design cut in wood or metal, or a block cast or electrotyped from the type or the engraving; and the impressing is effected by the press or machine presently to be described.

Types are cut, cast, or otherwise formed from various materials, though the printer recognises only two kinds—wooden ones, which are cut to form the larger letters used in placards, and metal ones. All books and newspapers and the great bulk of jobbing work are done from the last named (see Type).

A complete assortment of type of any one particular style is called a 'fount,' and may vary in amount to any extent, according as it may be required in large or small quantities. The individual type is a piece of metal about 1 inch long with a letter, point, comma, or other printing device cut in relief on one end as shown in fig. 1. The notch shown on one side is to enable the compositor to place it right side up when 'setting' without the trouble of looking at the letter. The different founts are arranged in one or more pairs of 'cases,' a 'lower' and 'upper' case, the former holding the small letters (technically called 'lower case' letters in consequence), figures, commas and points, spaces to put between the words, 'quads,' &c. The upper case holds the capitals, small capitals, and the less often used 'sorts.'

Fig. 2.—Cases.

thin slips of wood, are shown diagrammatically in fig. 2. The lower case is arranged not alphabetically, but so that the letters most used will be nearest the compositor's hand and have the largest

compartments, an ingenious arrangement for saving labour. The arrangement of the lower case varies slightly in different places, but the principle is the same in all. The proportion of the different letters of the English language in a fount of types is rather curious, and is shown in the following table:

a	8,500	h	6,400	o	8,000	u	3,400
b	1,600	i	8,000	p	1,700	v	1,200
c	3,000	j	400	q	500	w	2,000
d	4,400	k	800	r	6,200	x	400
e	12,000	l	4,000	s	8,000	y	2,000
f	2,500	m	3,000	t	9,000	z	200
g	1,700	n	8,000				

Provided with a metal instrument called a setting-'stick,' shown half-filled with type in fig. 3, and with his 'copy' before him, the compositor picks up the necessary letters, &c. one by one, arranging them in lines in the stick, which may be

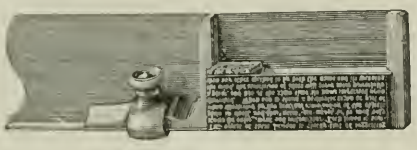

Fig. 3.—Setting-stick.

regulated to any width of line; each line is carefully spaced out to fit accurately into the stick before proceeding to the next, any *italics* or other sorts required being got from other cases. When the stick is full the matter is carefully lifted with the fingers, aided by the setting-rule, a piece of brass rule used in setting the lines, and shown in fig. 3, and put into a galley—a brass tray with wooden sides, about 18 or 20 inches long as used in setting such a book as the present work. This galley when filled contains about a page of matter in one long column, which is kept together by wedges driven in against the sides. A proof is taken at a hand-press, and this is read by a trained reader to correct any errors which the compositor may have made. These corrections are marked on the margin of the proof, and most of the signs and marks used are shown in the specimen given in the article PROOFS. When the printer's errors have been corrected by the compositor a 'clean' proof is taken for the author, and when his alterations are given effect to, the type is ready to be made into pages. If a short number of the book is required, say only a few hundreds, it is usually printed direct from the type; but where large numbers are required, or future editions expected, it is generally either Stereotyped (q.v.) or Electrotyped (see ELECTRO-METALLURGY), in either of which cases the type is not used for actual printing. In any case the type is taken from the galleys and arranged in pages, and the skill displayed by compositors in handling them without allowing any to drop out is very wonderful. The pages are 'locked' up by means of wedges in iron frames called 'chases' (Fr. *châsse*, 'a frame'),

Fig. 4.—Chase.

one of which with four pages is shown in fig. 4. Books are generally printed in sheets of sixteen pages, or multiples of sixteen (32, 64, or 128); in the latter case, however, they are cut into sheets of sixteen after being printed. In making up the pages to print a sixteen-page sheet, two formes, as the chases containing the type are called, are required, one for each side of the sheet. If a printed sheet of sixteen pages be opened out, the pages will be seen to be arranged in the following order:

Inside of Sheet.

7	10	11	9
2	15	14	3

Outside of Sheet.

9	12	6	8
4	13	16	1

And the pages in the chase must be so arranged, or 'imposed' as it is called, that, when printed, they will so appear. When ready for printing or stereotyping, as the case may be, another proof is read for final correction. In some cases where great accuracy is required, such as in the present work, as many as six or eight proofs are 'read' at different stages.

When the types have been printed or electrotyped and returned to the caseroom they are distributed by the compositors into the cases again for further use; and this can be done with wonderful rapidity, though great care must be used to avoid putting the letters into the wrong boxes. Several very ingenious machines have been invented for setting type which have been more or less successful. They are worked something after the manner of Typewriters (q.v.), and are described in the article TYPE-SETTING MACHINES. Several of the latest of these cast and set the type by one movement. This saves the labour of re-distributing the types, as when done with they are melted again. These machines are used for newspaper work.

In most printing-offices the men govern themselves by a voluntary association called a 'chapel,' which, although often (but not necessarily) connected with the printers' society, is independent so far as the individual affairs of the office are concerned. The office-bearers are called the 'father' and 'clerk' to the chapel, and it has elaborate sets of rules for regulating trade and personal affairs within the office.

Letterpress printing surfaces are coated with ink (see INK) by means of 'composition rollers.' These consist of cylinders of small diameter covered with composition made according to various recipes. Amongst them are glue, treacle, and Paris white; glue, sugar, and glycerine; glue, glycerine, sugar, and india-rubber, &c. These are melted, mixed together, and cast in cylindrical moulds of various diameters, according to the requirements of the machine or press. The glue and treacle composition was first used for printing by the engineers Donkin and Bacon in 1813; up to this time the types having been inked by pelt balls. The present system of inking on machines was invented by Mr Edward Cowper in 1818. Leather and other substances were tried at first, and the machines in which they were used were discarded owing to the unsatisfactoriness of their rolling or inking arrangements. A good roller must be tenacious of ink, semi-elastic, and retain its suction. It must not shrink, become hard in cold weather or soft in hot weather. The recipe for making it is varied according to the machine for which it is required—whether working on fine surfaces such as engravings, or at a high speed, as for newspaper work.

The earliest known representation of a printing-press is dated 1507, and it pictures an apparatus which is little more than a modification of the ancient wine-press. The essential feature is a flat

board, since known as a platen, which is movable vertically, and presses on a forme of type laid on an unresisting hard surface parallel to it. The two, between which was the paper, were brought together by a powerful screw, and thus the paper was squeezed down on the forme. This rudimentary appliance was improved from time to time, as is shown in various pictures of printing-office interiors. The wooden printing-press was brought to its ultimate degree of perfection in the later part of the 17th century. Moxon, the first technical writer on printing, described in 1683 what he called 'a newly invented press.' This was the old wooden press as improved by Blaeu of Amsterdam (fig. 5).

This press continued to be generally used until the close of the 18th century. About 1800 Charles Mahon, third Earl Stanhope, was instrumental in producing a much improved printing apparatus.

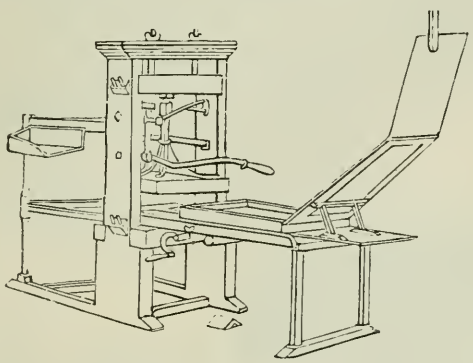

Fig. 5.—Old Common Press.

The press which bears his name was made entirely of iron, and the strength thus obtained enabled a forme to be printed on it double the size of that which could be done on a wooden press. There was a most ingenious system of links and levers, by means of which the approach to the type of the platen, and its withdrawal, were accelerated. The greatest leverage and consequently the greatest pressure were obtained when the forme and platen came into contact. These arrangements enabled the pressmen to print at the rate of 200 per hour on one side of the sheet or 100 per hour on both sides. After this several inventors turned their attention to the improvement of the hand-press. Clymer, an American, in his Columbian press, discarded the screw, the central feature of previous presses, and gained his power from a combination of powerful levers. About 1823 an excellent press, called the Albion, was brought out by Mr R. W. Cope of London, in which the pressure was gained by forcing an inclined bar of steel from a diagonal to a vertical position, forcing down the platen, the impression taking place when the piece of steel was brought into the vertical position. The Columbian and the Albion presses enabled the printer to print on one side of the paper at the rate of 250 sheets per hour. Such presses are now, except for peculiar kinds of work or when very few impressions of a forme are required, quite obsolete, being superseded by 'machines' on which the various operations of press-work are done more or less automatically.

The earliest inventors of 'printing' machines coupled together the two arts of printing on paper and on calico and other textile fabrics. Adkin and Walker in 1772 patented a machine which was the type of a modern rotary letterpress machine. It was 'for stamping and printing' on paper, cotton, and other cloths, 'whereby the printing on such materials would be greatly facilitated and rendered much less expensive, and more perfect and exact.' The words fully and clearly indicate the advantages of rotary over flat platen printing. Amongst other suggestions of a cognate nature made about this time the most remarkable was that of William Nicholson of London, the editor of a scientific journal. In 1790 he took out a patent which foreshadowed nearly every fundamental improvement even in the most advanced machines of the present day. He contemplated an apparatus in which formes or plates were to be fastened to the surface of a cylinder; the inking to be supplied by a roller and distributed by smaller rollers; the impression to be cylindrical, the paper being caused to pass between the printing cylinder and one covered with cloth or leather. Nicholson never actually constructed a machine, and although his patent was a marvellous forecast of the methods soon to be adopted in letterpress printing, he cannot be awarded the honour of being the inventor of the printing-machine.

Hitherto the evolution of the type-printing machine from the calico-printing machine has been completely overlooked by historians of printing, yet the connection is almost obvious. Nicholson's apparatus belonged to the same category. The distinction of first actually making a printing-machine was reserved for a German printer, Frederick König (q.v.), who commenced experiments with the modest, and, as it proved, mistaken view of accelerating by making more automatic the ordinary hand-press. He came to London in 1806, and patented a new platen-machine. The idea was but crude, and never put into execution. It is not unlikely that about this time König became acquainted with the ideas patented by Nicholson (see Goebel, *Friedrich König und die Erfindung der Schnell-presse*, Stuttgart, 1883). At any rate König abandoned his project for accelerating flat printing. In 1811 he took out a patent for what we would now call a single-cylinder machine—i.e. one in which the impression was given by a cylinder, the inking being done by rollers, and the paper carried through the apparatus on tapes. The type bed moved to and fro, and the cylinder had an intermittent or stop motion, affording time for the feeding of the sheets. The glue and treacle composition had not been discovered, and leather inking-rollers had to be used. Mr John Walter of the *Times* was so struck with the apparent possibilities of this method of printing that he engaged König to make for him a double-cylinder machine which should print two copies of a forme of the newspaper, but on one side only of the sheet at once. This was completed in 1814, and on the 28th November of that year a newspaper was for the first time in any country printed by a machine driven by steam-power. This machine printed 1800 impressions per hour, completing 900 sheets, and it was used by the *Times* for several years. In 1818 Edward Cowper invented several important improvements, including a flat ink-distributing table, with distributing-rollers, forme-inking rollers, and ink-fountain. These principles are still to be found in single-cylinder machines. Cowper was called upon to perfect König's machine and did so, mainly by taking away the old inking-apparatus and substituting his own. In the same year König patented a perfecting machine which resembled two single-cylinder machines placed with their cylinders towards each other. The sheet was conveyed from one cylinder to the other by means of tapes so arranged that in the course of its track it was turned over and the second side presented to the second cylinder. At the first cylinder the sheet received its impression from the

first forme, and at the second cylinder it received its impression from the second forme. Cowper also improved on this machine, which printed 750 sheets on both sides of the paper per hour. The principle of the first perfecting machine has not been considerably departed from in subsequent machines of the same class, but improved methods have been devised for carrying the sheet from one cylinder to the other and turning it.

Reference, extremely brief and imperfect, has now been made to the origin of two out of the three distinct classes of printing-machines at present in use. These are, first, the single-cylinder machine, printing one side of the sheet at one operation, from a forme lying on a flat bed; second, the double-cylinder or perfecting machine, printing both sides of the sheet at once, also from a forme on a flat bed. The third class comprises the rotary machines, printing both sides, but from a circular forme—the impressing surface, as well as the printing and the inking surface, being cylindrical, and capable of continuous rotation. The machines of the first and second classes are adapted for single sheets of paper; the rotary machines print reels or continuous webs, the portion forming a sheet being severed after printing. It is in this latter class of machines that the greatest improvements—amounting almost to a revolution in the art of printing—have been achieved. (For a technical account of the several classes, see *Principles and Progress of Printing Machinery*, by the present writer, Lond. 1889.) Limitations of space preclude more being given here than a bare list of successive improvements.

In 1790, as already mentioned, Nicholson patented a rotary machine, but he never constructed one. In 1813 Bacon and Donkin patented a machine in which the types were fixed on a revolving prism, the ink being applied by a roller, and the sheet of paper wrapped on another prism. The machine was a failure, although it embraced an important feature, the inking-roller made of composition. Three years afterwards Cowper patented a method for printing paper for paper-hangings and other purposes. This embodied another valuable feature—the taking a cast from the type and bending the cast round a cylinder. It was a far more practical idea than the subsequent one of Rowland Hill, who, to procure a curved printing surface, proposed the use of tapering types to be fixed on the cylinder. In 1848 Applegath invented a machine, the type-cylinder of which was vertical and nearly 6 feet in diameter, around it being placed eight other cylinders,

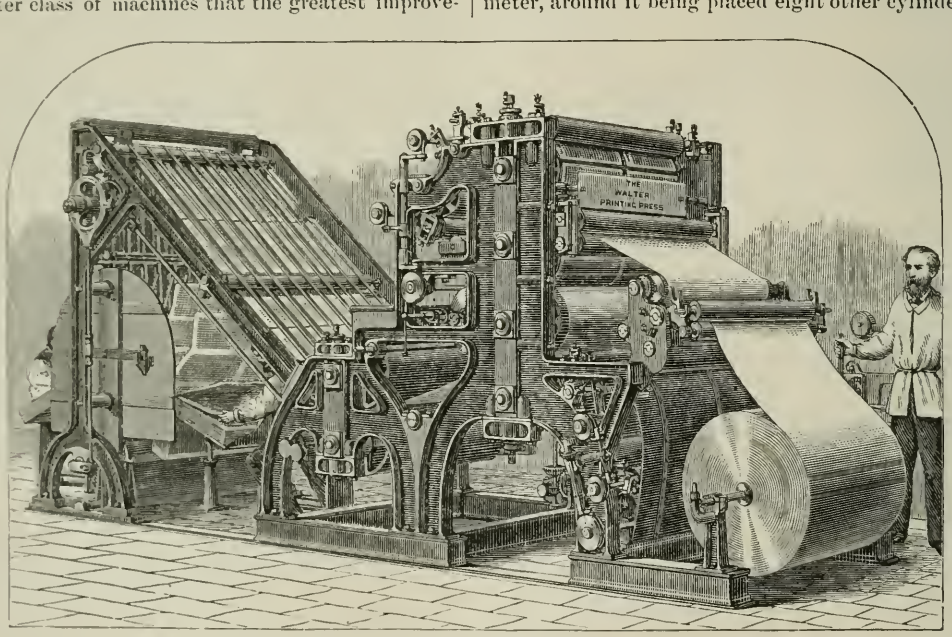

Fig. 6.—The Walter Press.

containing sheets of paper to be printed. These were fed in from a horizontal position, and then brought to the vertical position. In 1857 the *Times* discarded this machine in favour of one patented by Hoe of New York, very similar in construction, but the cylinders were horizontal. It was found that the complication arising from eight or ten feeders was most objectionable, causing frequent stoppages, excessive waste of paper, and great risk to the machine and the material, while the working cost was heavy. Each of the machines printed on one side only. They were the first machines fitted with 'flyers'—a device for mechanically delivering or taking off the sheets. It was, however, considered at the *Times* office that the acme of improvement could only be obtained by constructing a machine simple in its arrangements, capable of printing both sides of the paper at one operation, and which could print, not single sheets, but continuous webs of paper, thus dispensing with layers-on. There were enormous difficulties in the way of printing, cutting, and delivering the paper, difficulties which the non-professional reader could by no means realise. In 1866 a machine of the kind was constructed under the superintendence of Mr J. C. Macdonald, the manager, and Mr Calverley, chief-engineer of the *Times*. The Walter Press, as this machine was named, has since been slightly improved, but remains practically the same, and is shown in fig. 6. The types are stereotyped by means of a papier-maché mould, which, being bent inside a hollow cylinder, produces, when cast, a stereotype which fits on the printing-cylinder of the machine. The paper, unwinding from the reel, first passes between damping-cylinders, then over the printing-

cylinders, and is finally cut and delivered at the other end of the machine. Two boys and a man, who superintends the machine, supply all the manual labour required. The speed is about 10,000 perfect sheets per hour, equal to 20,000 impressions by the apparatus previously mentioned. The more recent machines have an attachment for folding, which make two, three, or four folds as required.

Mr Walter of the *Times* is entitled to the honour of being instrumental in introducing the system of rotary printing for news-work, just as his father deserves that of having introduced steam machine-printing. The Walter press was soon adopted as the pattern of a number of machines constructed in Britain and abroad. Some of these machines much developed the idea of the Walter, and embodied fresh and important improvements. In 1870 Messrs George Duncan and Alexander Wilson, of Liverpool, brought out their 'Victory' machine, which included the folding arrangement since added to the Walter press. By this apparatus newspapers of various sizes are printed, folded, delivered, and counted into quires or any portion required, at the rate of 200 per minute.

Since about 1870 the rotary system of printing has been gradually adopted in the offices of all newspapers having even moderately large circulations. Factories for producing rotary machines have been established in various parts of England, while many such machines have been imported from France, Germany, and America. The most improved and the fastest machines made up to the present time are those of Messrs Hoe & Co., of New York and London. The most improved of these machines print four or six page papers at the extraordinary speed of 48,000 per hour, or 800 per minute. Papers of eight, ten, or twelve pages can be printed at a speed of 24,000 per hour, and a sixteen page paper at 12,000 per hour. The papers can be pasted down the centre margins if required, and counted as delivered in quires of any number fixed upon. The machine delivers the papers, inset, pasted, cut top and bottom, turned out as compact as a pamphlet, and, by the addition of a device largely used in America, even folded and wrappered ready for post. This speed is effected by using a reel of paper of double width, about 8 feet wide, on which can be printed duplicate sets of plates. So greatly has the art of Stereotyping (q.v.) been improved that eight stereo-plates from one forme can now be moulded, cast, and finished ready for the machine in eight minutes. Fig. 7 shows the double-web Hoe machine.

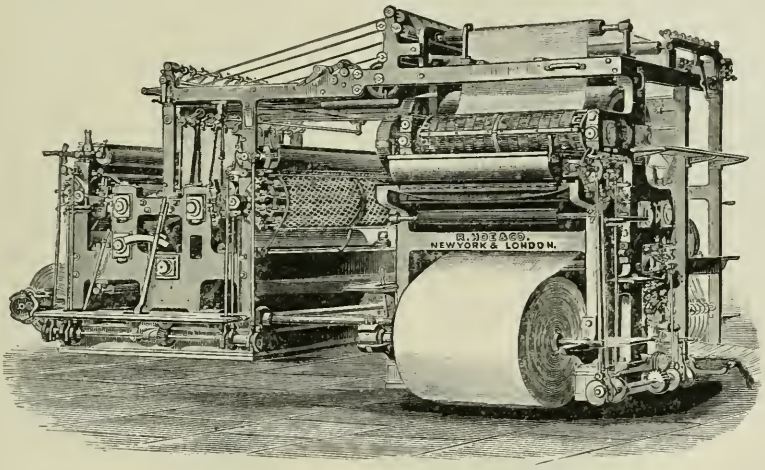

Fig. 7.—Hoe Double-web Machine.

The printing business is divided into three departments — those concerned respectively with jobbing or commercial work, with book-work, and with news-work. The improvements of late years in the mechanism and the processes of the first two are equally important with those in the last. The character of ordinary jobbing work has been greatly bettered by the liberal use and correct selection of colours, by the introduction of ground tints, and by the artistic taste infused into the design. The typefounders have provided the printer with more beautiful types and more diversified ornaments, and both press-man and compositor have utilised with intelligence and skill the materials at their command. Jobbing work is chiefly done on small platen-machines, invented by an American, G. P. Gordon, and introduced into Britain as 'Minerva Presses' in 1866. There are many varieties now made of this apparatus. Larger work is done on machines having one or two cylinders. Those of the 'Wharfedale' pattern, invented about 1860 by William Dawson and David Payne of Otley, Wharfedale, Yorks, have one cylinder, and print only one side of the paper at a time.

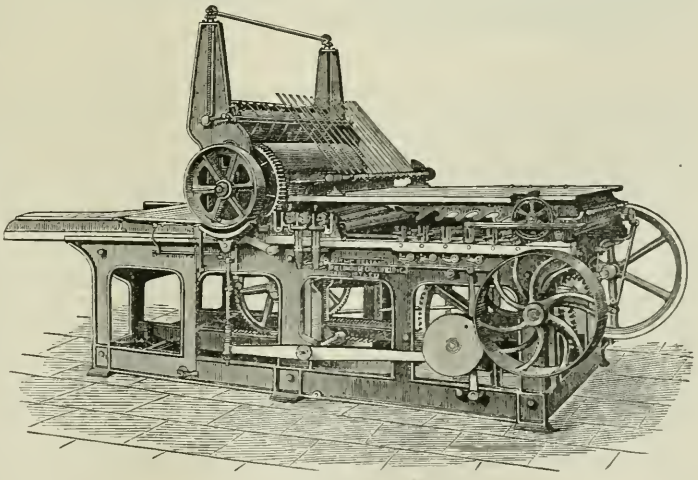

Fig. 8.—Single-cylinder Machine.

The essential parts of the single-cylinder machine (fig. 8), now constructed by engineers in Europe and America with small alterations in pattern, may be regarded as five: the impression appliances

of the cylinder; the arrangements for carrying the forme of type up to and under the cylinder, by contact of which it receives the impression; the inking of the type; the laying on of the sheet; the taking off or delivery of the sheet when printed. The cylinder, which is a hollow drum, having an opening on its under side, is placed almost in the middle of the machine. The table of the machine on which the forme is placed has racks on its under surface gearing into the traverse wheels, from which it derives motion to and fro. By means of racks it also causes the rotation of the cylinder by which the impression of the forme is effected. The inking system may be thus outlined. There is at the extremity of the machine and running across it a duct or ink reservoir, with an adjustable side-piece called the knife, which regulates the outflow of ink. A composition roller in motion, called a vibrator, takes a streak of ink periodically and transfers it to the ink-table, which forms part of the table and of course moves backward and forward. The ink is evenly spread or distributed over the ink-table by 'distributors.' The table then passes under the inking-rollers which alone touch the forme and give it the proper coating of ink. The distributors and rollers are coated with 'composition,' referred to on p. 410. The feeding apparatus is also ingenious. A pile of paper is laid on to the desk-like table shown at the right-hand side of the machine, and a boy stands at the end or at the front side of it and 'strokes' the sheets down till the front edge of one comes in contact with a series of metal fingers or clutches called grippers. These open and take a sheet by its edge, and hold it secure while the cylinder is turning round, and the printing taking place. At a certain point the grippers release the sheet, which then goes into the taking-off apparatus. A second set of grippers seize it and carry it round the wooden flyer cylinder, from whence it emerges on to travelling tapes. A large comb-like appliance called the gate oscillates up and down, having the sheet in front. The pressure of the air causes the sheet to adhere to this until it assumes a horizontal position, when it drops on to the taking-off board. While the first side of the sheet is being printed, two points, by an ingenious arrangement, make small holes in the paper; and when the sheet is turned to print the second side, these holes are again placed on the 'points,' thus ensuring correct register.

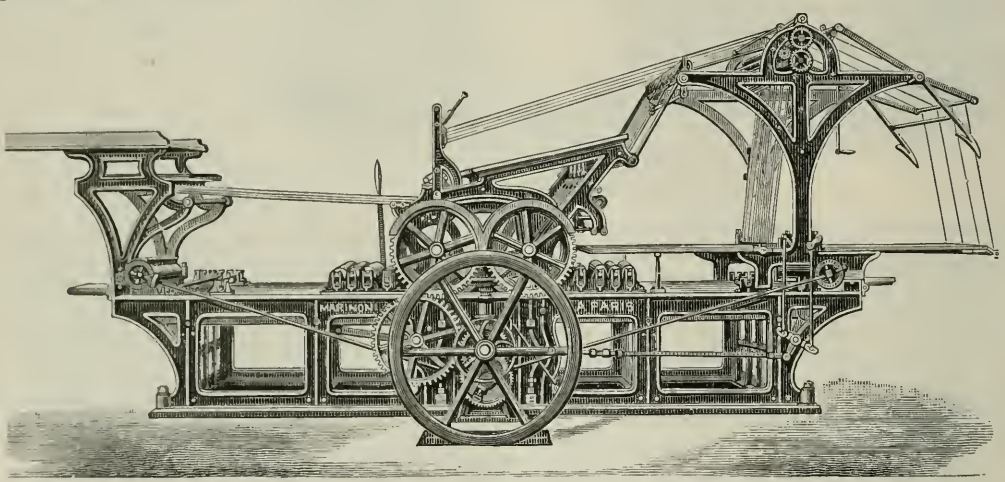

Fig. 9.—Perfecting Machine.

Machines with two cylinders are called perfecting machines because they perfect or print both sides of a sheet before delivering it. Generally they may be said to be duplicated single machines, with two printing-cylinders, two tables for type, and an inking apparatus at either end, much as described under the single-cylinder machine. The sheet is printed on one side at the first cylinder, when a set of grippers on the second cylinder take possession of it and print the second side, and it is delivered by the flyer as described. The varieties of these machines are numerous, and fig. 9 shows the *Marinoni*, a well-known type, used in the printing of the British editions of the present work. These machines can print in the very finest manner from 1000 to 1500 perfected sheets per hour, according as they may be complicated with illustrations or not.

When the types are to be printed from direct, as already mentioned, the chase containing the pages is put on the bed of the machine. When stereotype or electrotype plates are used they are carefully dressed to an exact size and thickness, the latter about $\frac{3}{32}$ths of an inch. The requisite number of wooden blocks are then put on the machine-bed, locked in a chase. These blocks are of the proper thickness to make up the plates to type-height (about 1 inch). The plates are fastened to the blocks by brass catches at the sides and ends, and when locked up are as solid as type.

Before printing, however, a laborious process called *making ready* has to be gone through. When many wood-engravings are in the pages several days may be taken up making ready a single sheet. This process is for the purpose of making the impression equal all over and properly printing the wood-engravings, and can be judged of by comparing a carefully printed book with a daily newspaper, which is printed just as it comes without any making ready. It is too technical for detailed description within our limits.

It is not long since that it was a firm article of belief among printers that fine work could not be done except on a press provided with a platen. And up to quite recently all paper was first thoroughly wetted, then printed, then dried, and then pressed to restore the surface, of which the damping deprived it, and to give it a certain gloss. Between the forme and the platen of the press or the cylinder of the machine a thick, soft, yielding blanket was placed, which was supposed to produce a better impression from the inequalities of engravings and type. There has been a radical change in opinion and practice on these important points. It has been found, since machines

have been brought to their present degree of perfection, that they give far superior results to those from presses—their impression is stronger, more solid, and more uniform, and the sheets can be laid on them with a precision unattainable with hand-presses. Paper is not now made spongy and stretchable by being wetted, and the result of working it dry is that the type is brought up with greater brightness, and the delicate lines of engravings are printed finer, clearer, and cleaner. Improvements in ink-making have much conduced to this desirable result. Paper has been produced for book-printing with a specially prepared surface, which admits of a far more excellent impression than that formerly procurable. The soft blanket has been discarded, and the packing or covering of the cylinder is now generally as hard as it can be got. The aggregate results of these alterations may be seen by a comparison of the present issues of an illustrated newspaper with those of fifty years ago. Up to about 1840 there was actually no press strong enough to properly print a woodcut of 48 square inches in superficies; now, woodcuts of 2000 square inches, or 50 inches by 40, are printed in the most perfect manner. The coloured supplements of the pictorial journals are often admirable reproductions of works of high art; it is within the memory of persons of middle age that the first crude attempts were made to print such pictures.

Bibliography.—*Historical:* In addition to the works referred to in the text may be mentioned Karl Faulmann, *Illustricrte Geschichte der Buchdruckerkunst* (Vienna, 1882), his *Die Erfindung der Buchd. nach der neuesten Forschungen* (Vienna, 1891); Theo. de Vinne, *The Invention of Printing* (New York, 1877); and Van der Linde, *Geschichte der Erfindung der Buchd.* (3 vols. Berlin, 1886). There is no complete history of printing in the English language, but in Bigmore and Wyman's *Bibliography of Printing* (3 vols. 1880–86) some of the most useful books will be found under the names of Ames, Arber, Blades, Dibdin, Herbert, Hansard, Humphreys, Hessels, Luckombe, Ottley, T. B. Reed, Sotheby, Timperley, and Watson.

Practical.—Southward, *Modern Printing* (4 parts, 1898–1900), and *Printing Machines and Machine Printing* (1888); Waldow, *Illustrierte Encyklopadie der Graphischen Kunste* (Leip. 1884); Desormes, *Notions de Typographie* (Paris, 1888); F. J. F. Wilson, *Printing Machines* (3d ed. 1885); F. J. Jacobi, *Printing* (1890); *The American Dictionary of Printing and Bookmaking* (1891–94); Ringwalt, *American Encyclopædia of Printing* (New York, 1871). Besides, a multitude of small yet useful books have been written on separate branches, and for the use of professional students of the art. See also the articles Biblia Pauperum, Book, Book-club, Illustration, Lithography, Paper, Press (Freedom of the), Proofs, Stereotyping, Types, Writing.

Prior. See Monastery, Abbot.

Prior, Matthew, was born 21st July 1664. Some doubt prevails as to his birthplace; but the bulk of the evidence points to Wimborne Minster in East Dorset. His father is said to have been a joiner, who, coming to London, probably to educate his son, took up his abode in Stephen's Alley, Westminster. Young Prior went to Westminster School, then under the redoubtable Dr Busby. His father died, and, his mother being unable to pay his school-fees, he fell into the care of his uncle, a vintner in Channel (now Cannon) Row, who took him into the bar to keep accounts. Here his familiarity with Horace and Ovid attracted the attention of Charles, Earl of Dorset, and other visitors to the Rhenish Wine House, with the result that he returned to Westminster, his uncle finding him in clothes, and Dorset in books. At Westminster he formed a life-long friendship with the two sons of the Honourable George Montagne, the elder of whom afterwards became Earl of Halifax. In order to follow his friends to Cambridge, Prior, against Lord Dorset's wish, accepted a scholarship from the Duchess of Somerset at St John's College. He was admitted Bachelor in 1686, and in the following year wrote with Charles Montague the clever parody of Dryden, entitled *The Hind and the Panther transvers'd to the Story of the Country-mouse and the City-mouse*, which, according to tradition, greatly annoyed Dryden. In April 1688 Prior obtained a fellowship; and his composition of the yearly college tribute to the Exeter family, a rhymed excursus upon Exodus, iii. 14, led to his going to Burleigh as tutor to Lord Exeter's sons. Lord Exeter shortly afterwards removed to Italy, and Prior applied (through Fleetwood Shepherd) to his former patron Dorset for advancement. He was, being then twenty-six, made secretary to Lord Dursley, afterwards Earl of Berkeley, then going as ambassador to the Hague. In Holland Prior remained some years, finding especial favour with King William. In 1697 he brought over the Articles of Peace at the treaty of Ryswick; and, after being nominated Secretary of State for Ireland, he was made secretary in 1698 to the Earl of Portland's embassy to France, continuing this office under the Earl of Jersey. In this capacity he found favour both with Anne and Louis XIV. In 1699 he became an under-secretary of state, the university of Cambridge made him an M.A., and he succeeded Locke as commissioner of trade and plantations. In 1701 he entered parliament as member for East Grinstead. Under Anne he joined the Tories, and in 1711 was employed in the preliminaries of the peace of Utrecht, going to Paris as ambassador in the following year. With the queen's death in 1714 came the triumph of the Whigs, and in 1715 Prior, returning to England, was impeached and imprisoned. In 1717 he was excepted from the Act of Grace, but was, none the less, subsequently discharged. The remainder of his life was passed chiefly at Down-Hall in Essex, a country-house purchased partly with the profits of a subscription edition of his poems and partly with the assistance of his friend Lord Harley, at whose seat of Wimpole he died, 18th September 1721, being then in his fifty-eighth year. He was buried in Westminster Abbey, under a monument decorated with his bust by Antoine Coysevox, given to him by Louis XIV. His portrait was painted by Richardson (National Portrait Gallery), by Belle (St John's College), Kneller, Dahl, and others.

Of Prior's abilities as a diplomatist there are diverse opinions. Pope sneered at them. But Bolingbroke and Swift extolled them; and it is stated that the archives at Paris show him to have been far abler and more resourceful than is generally supposed. As a poet, in which capacity he is now remembered, he holds a unique position. Without much real sentiment or humanity, his verses have a wit, a grace, a neatness and a finish, which link him to the lighter Latin poets on the one hand, and to the best French writers of familiar verse on the other. Cowper praised his 'easy jingle,' Thackeray 'his good sense, his happy easy turns and melody.' He collected his poems, described by himself as consisting of 'Publick Panegyrics, Amorous Odes, Serious Reflexions, or Idle Tales' (many of which had been contributed to Dryden's and other miscellanies), in 1709, and again, in extended form, in 1718. By this latter issue he made £4000. His more ambitious pieces, *Solomon on the Vanity of the World* and a paraphrase of the old ballad of the *Nut Brown Maid*, are not now thought to be his best, although they had considerable popularity with the readers of the 18th century. But a third long poem, *Alma; or, the Progress of the Mind*, an imitation of Butler, is full of wit and waywardness. His *Tales* resemble the French *contes* too much in their objectionable

qualities to be palatable to the English taste. He survives mainly by his purely playful efforts, his lyrics and his epigrams, not a few of which are unsurpassable. In the kind of piece known to the French as *vers d'occasion* he is unrivalled, and his beautiful stanzas to *A Child of Quality* have been as fortunate as Gray's *Long Story* in setting the tune to a host of versifiers. In 1740, long after his death, two volumes were published, one containing alleged *Memoirs*, in which there is little of his, and the other a number of posthumous verses, among which are some of his best. These are included in Evans's two-volume edition of 1779. Thackeray wrote admirably of Prior in his *English Humourists* (1853). See his *Selected Poems*, edited by the writer of this notice (Parchment Library, 1889); an article by Mr G. A. Aitken in the *Contemporary Review* for May 1890; and the edition of Prior's works by R. Brimley Johnson (2 vols. 1892).

Priscian (Lat. *Priscianus*), surnamed CÆSARIENSIS, born or educated in Cæsarea, is in point of reputation the first of Latin grammarians; his treatise was in universal use as a text-book during the middle ages. Priscian flourished in the beginning of the 6th century: Paulus Diaconus calls him a contemporary of Cassiodorus (468–562 A.D.). He taught Latin at Constantinople, and enjoyed a government salary. The work which has preserved his name is his *Commentariorum Grammaticorum Libri XVIII.* The first sixteen books treat of the different parts of speech; the remaining two, of syntax. The work shows great learning and good sense, and contains quotations from many Greek and Latin authors no longer extant. Priscian also wrote six smaller grammatical treatises, and two hexameter poems of the didactic sort, *De Laude Imperatoris Anastasii* and a free translation of the *Periegesis* of Dionysius. The best edition of the grammatical works is that by Hertz and Keil in Keil's *Grammatici Latini*, vols. ii. and iii. (1855–60); of the poems, by Bährens, in *Poetæ Latini Minores*, vol. v. (1883).

Priscillian, the chief propagator of the doctrines professed by the sect known from his name as Priscillianists. They spread widely in Spain during the last third of the 4th century, and lingered there till the middle of the 5th century. The first seed of their doctrines is said to have been carried into Spain by a Memphian named Marcus, whose earliest disciples were Agape, a Spanish lady, and Helpidius, a rhetorician. Priscillian was a man of noble birth, pious and well educated; and his eloquence and nobility of character soon gathered round him a group of devoted followers, including two bishops, Instantius and Salvianus. From their hands he received episcopal ordination, and he established his see at Avila (*Ávila*). Hyginus, bishop of Cordova, was the first to take alarm, but his measures were so gentle that he himself was covered with reproaches by the ultra-orthodox and fanatical. Priscillian's most determined enemies were Idacius, bishop of Emerita (*Merida*), and Ithacius, bishop of Sossuba. He was condemned and excommunicated at the synod of Saragossa (381), with three others of the leaders of the party. They next went to Rome to clear themselves before the pope, but were denied audience, and at Milan on the return journey they met as little sympathy from Ambrose. Under the vacillating rule of Gratian, however, they prospered, but their hopes were dashed to the ground by the usurpation of Clemens Maximus. From the judgment of the synod of Bordeaux (384) Priscillian appealed like Paul to Cæsar, and was at length summoned to appear at Treves. Martin of Tours was in favour of tolerant measures, but after his departure the fanatical party prevailed, and Priscillian, with others of the party, was condemned and put to death—the first who suffered death for heresy (385). Many Priscillianists recanted after the synod of Toledo (400), and soon after that of 447 they disappear altogether. Their doctrines contained Manichæan and Gnostic elements, strange cosmical speculations based on primitive dualism, the doctrine of emanations and astrological fatalism. They practised rigid asceticism, and eschewed marriage and the use of animal food. One damning blot on their morals was that absolute veracity was only obligatory between themselves. Graver charges still were made against their morality; but it should be remembered that the only accounts we have are those of bitter enemies, and their principles, originally obscure enough, have been made darker by a cloud of calumny. 'If the Priscillianists violated the laws of nature,' says Gibbon, 'it was not by the licentiousness but by the severity of their lives.'

See Mansel's *Gnostic Heresies* and Neander's *Church History*; also Mandernach's *Geschichte des Priscillianismus* (Treves, 1851). Schepps claims to have discovered some of his writings; these he edited in vol. xviii. of the *Corpus Scriptorum Ecclesiasticorum Latinorum* (Vienna, 1888).

Prism, in Geometry, a solid figure which can be most easily conceived of if we imagine a number of plane figures (triangles, quadrilaterals, &c.) exactly similar in form and size to be cut out of paper or any thin plate, and piled one above the other, and then the whole pile to become one body. It will thus be seen that the top and bottom of the prism are similar, equal, and parallel to each other, and that the sides are plane figures, rectangular if the prism be 'right' (i.e. if in the above illustration the pile of plane figures be built up perpendicularly), and rhomboidal if the prism be 'oblique' (i.e. if the pile slope to one side); but under all circumstances the sides of a prism must be parallelograms. The top and bottom faces may be either triangles, squares, parallelograms, or quadrilaterals of any sort, or figures of five, six, seven, &c. sides, provided only both are alike; and the number of sides in the plane figure which forms the top or bottom of course determines the number of faces of the prism; thus, in a triangular prism, there are five faces in all (three sides and two ends); in a quadrangular prism, six faces (four sides and two ends), &c. If two prisms, one being 'right,' and the other 'oblique,' have their bases of equal area, and be of the same vertical height, their solid content is the same, and is found by multiplying the area of the base by the vertical height. The parallelopiped is a quadrangular prism, and the *cube* is a particular case of the parallelopiped.

PRISM, in Optics, is a triangular prism of glass or other transparent substance, its two ends being isosceles triangles, and having most frequently a very acute vertical angle, which gives the prism the appearance of a long wedge. The prism is a most important instrument in experiments on the refraction of light, and, in the hands of the most eminent optical philosophers, has been the means of largely adding to the science of optics. See OPTICS, REFRACTION, SPECTRUM.

Prisoners of War are those who are captured from the enemy during naval or military operations. By the laws or recognised principles of war, the entire people of a vanquished town, state, or nation become the absolute property of the victors. In ancient times the treatment of prisoners of war was very severe. In the Greek wars it was no uncommon thing to put the whole adult male population of a conquered state to the sword, while the women and children were enslaved. Although the putting to death of prisoners became less frequent, they and their families were commonly reduced to slavery to as recent a period as the 13th

century. The act of Napoleon in putting to death the Turkish prisoners of war at Jaffa in 1799 was universally condemned, and is probably the last instance of such barbarity. Notwithstanding frequent exchanges, large numbers of prisoners accumulate during war. In 1811 about 47,600 French were prisoners in England, while 10,300 English languished in the prisons of France. By the end of the Franco-German war of 1870–71 about 300,000 French troops had been sent to Germany as prisoners of war, many of the officers being released on Parole (q.v.). During the South African war, 1899–1900, many of the Boer prisoners were sent for safe keeping to St Helena and Ceylon.

Prisons. It is only within recent times that imprisonment has been studied as a scientific process by means of which certain high objects are to be attained, and which therefore ought to be conducted according to a defined system founded on recognised principles. It used to be believed that nothing more was required than to ensure the security of the victim or culprit, by chains and fetters if necessary, unless it were to inflict on him some further bodily pains and penalties, the smallest of which was to feed him with 'the bread of affliction and the water of affliction' ordered by Ahab for the prophet Micaiah. Imprisonment was not mentioned in the Anglo-Saxon laws as a punishment, but was enforced when an offender could not find a surety. In course of time, however, it was authorised by the common law as a punishment, as well as specified by statute for particular offences; nevertheless gaols were actually used more for securing the persons of those committed to them than as places of punishment. Under the common law all gaols belonged to the king, and by 5 Hen. IV. chap. 10 it was enacted that none but the common gaol should be the place of committal for offenders brought before a justice of the peace. But there were many 'franchise' gaols owned by great persons, or by towns and liberties under their charters, which were lawful places for carrying out imprisonment ordered by the persons or bodies to whom these privileges were granted as a part of the criminal jurisdiction placed in their hands. In many cases these bodies had the power of life and death.

In the reigns of Edward VI. and Queen Elizabeth a new description of place of confinement was introduced—viz. the 'bridewells' and 'houses of correction' for vagabonds, &c. By James I. chap. 4, every county was required to provide such an establishment with suitable instruments and appliances in it for setting idle people to work. Another sort of prison is of quite recent introduction—viz. the reformatory and industrial school, institutions which are under private management, but derive the greater part of the funds by which they are maintained from public sources, and are subject to certain general rules and conditions intended to secure efficiency and to prevent abuse, compliance with which is ensured by government inspection. These institutions are for the reception of juveniles whom modern philanthropy has rightly and successfully contended should not be confined in the same establishments as adults, nor treated in the way which is most appropriate for the latter. Reformatories are places of punishment for juveniles under sixteen years of age who are convicted of crime, and sentenced to ten days' imprisonment or more. Industrial schools are not places of punishment at all, but are intended to prevent children becoming criminals through parental neglect or misconduct. A child must be under fourteen years of age to justify his being sent to an industrial school. There are therefore (1) prisons to which adults are sent for punishment and reformation; (2) prisons to which juveniles are sent for punishment and reformation, called reformatory schools; (3) prisons or places of compulsory detention to which juveniles are sent as a preventive measure, called industrial schools. To the first of these are sent also persons who are charged with a crime to await their trial, and persons committed by county courts for refusing to pay debts which they have means to pay, or by other courts if they cannot find sureties when ordered for any reason to do so. The course of events has led to the prisons of the first of these three classes being separated into two divisions which have a distinct history. One of these comprises the prisons which are governed by the laws relating to places in which criminals sentenced to penal servitude may be confined; the other comprises the ordinary prisons in which all sorts and classes of prisoners may be confined, but in which, as matters now stand, prisoners under sentence of penal servitude pass only the first few months of their sentences. The former are generally designated convict prisons; the latter are now styled local prisons.

The punishment of penal servitude had its origin in the system of transportation, and transportation itself had its origin in banishment or exile. This was expressly forbidden by Magna Charta, but existed nevertheless as a practice, because a criminal who had incurred the sentence of hanging and had taken sanctuary to avoid his fate was permitted in some cases to escape his punishment if he exiled himself. In course of time the privilege of sanctuary was abolished by law (though its practice existed notwithstanding for some time afterwards), and consequently the system of self-banishment which grew out of it; but before then—viz. in the thirty-ninth year of Queen Elizabeth's reign—banishment had been legally established by the Vagrancy Act, which gave quarter sessions the power of transportation.

Transportation was sanctioned by law in the reign of Charles II. as a mode of dealing with incorrigible rogues, vagabonds, and sturdy beggars, as a punishment for attending an illegal prayer-meeting after a previous conviction of that offence, and to put down the moss-troopers of Northumberland and Cumberland. The transportation was not at first enforced by any direct action of the government, but those sentenced to it were left to carry out their sentences by removing themselves to the West Indies or elsewhere under penalty of hanging if they failed to do so; but in course of time the process became more systematised, and in 1718 it was found necessary to deliver them over to a contractor who engaged to take them to His Majesty's colonies and plantations in America on condition of his having property and interest in their services for a specified term of years. They were given over to slavery in fact, and the contractor at the termination of the voyage put them up to auction and sold their services to the highest bidder. In 1776 it became no longer possible to send these outcasts to America. Some of the colonies had for years past continually protested against the system; but the war of independence left no alternative but to put an end to it, and the government had to find some other mode of disposing of these criminals, estimated in 1778 at 1000 annually. This difficulty originated the practice of confining prisoners in hulks in the Thames or in the harbours of Portsmouth, Chatham, &c.

This was intended only as a temporary expedient pending the execution of an act devised by Blackstone, Eden (Lord Auckland), and Howard, for the building of penitentiaries in England, which were intended to provide a separate cell for each of the inmates, who were during their imprisonment to be

employed on useful labour. Chap. 74 of the 19th Geo. III., after reciting that 'the punishment of felons and other offenders by transportation to His Majesty's Colonies and Plantations in America is attended with many Difficulties,' and enacting that such offenders might be transported elsewhere, and that offenders who might be sentenced to be burned in the hand might instead be fined or whipped, proceeds to say that 'whereas, if many offenders convicted of crimes for which Transportation hath usually been inflicted were ordered to solitary imprisonment accompanied by well-regulated labour and religious instruction, it might be the means under Providence not only of debarring others from the commission of the like crimes, but also of reforming the individuals and inviting them to habits of industry, it shall be lawful to appoint supervisors who shall erect penitentiaries where such persons may be ordered to imprisonment and hard labour.' The first hulks were established in 1778; and this fatal temporary expedient serves to illustrate the sarcasm as to the superior permanency of temporary expedients, for the last hulk was not closed until a fire destroyed it in 1857; and in fact they had a perfect representative in Gibraltar prison, which was constructed on the model of a hulk and developed all the iniquities of these establishments, and which was only closed in 1875 after strenuous opposition to its abolition by the local naval and military authorities. Many years were destined to pass before the permanent penitentiary system became a fact. Great efforts were made to revive the transportation system, and in 1787 a new penal colony was founded in Australia. This with the hulks continued to form the punishment next in gravity to capital execution until the last hulk was closed in 1857 and the last batch of convicts was sent to Western Australia in 1867. It is not necessary to describe the hulk system, if system that can be called in which the inmates were herded together in unchecked association, where 'vice, profaneness, and demoralisation' developed, as might be expected, among persons of the basest character, of whom the worst and the most demoralised were likely soon to take the lead, and reduce all down to their own level. They were described by a committee of the House of Commons in 1832 as 'well fed, well clothed, indulging in riotous enjoyment by night, with moderate labour by day, so that life in them is considered "a pretty jolly life."' But the hulks flourished in full vigour for many years after this date; and in fact no attempt was then made to abolish them, which was the only way to put an end to the evils so forcibly commented on.

The history of the phases through which the control and supervision of the hulks passed is, however, of consequence, as it explains the present administration of the convict prisons and shows what methods failed, and furnishes warnings against adopting certain suggestions that are made from time to time. The hulks were at first, like all other prisons, placed under the management of the local justices, who appointed the overseer, and the overseer appointed the officers; the justices also made the overseer contractor for the maintenance of the prisoners, and as it was obviously his interest as contractor to cut short the supplies of food and clothing for the prisoners, they therefore by this measure contrived that his interest should be diametrically opposed to his duty and to the welfare of the prisoners in his charge. The supervision of the hulks resided in the Court of King's Bench, who steadily neglected their duty, and the inspector provided for by parliament was not appointed. In course of time and by degrees the Home Secretary usurped power over these establishments, and his action was endorsed by parliament in 1815; and their connection with the King's Bench was severed in 1825. An inspector was appointed, and after that a superintendent; and after some other changes the control and administration of the hulks was in 1850 vested in the Board of Directors of Convict Prisons, with whom it now rests. The control of Millbank Prison, Pentonville Prison, and Parkhurst Reformatory was confided to the same body.

Transportation to Australia, which was commenced in 1787, for many years provided for only a small part of the persons subjected to that sentence or whose capital sentences were commuted for transportation. Until 1816 an average of only 474 prisoners was transported annually to Australia, after that the average rose to 3000, and in 1834 amounted to 4920. Transportation in its most flourishing days was characterised by evils which rivalled if they did not sometimes surpass those of the hulks.

Whilst, however, it was in full vigour a step was taken, feebly and slowly indeed, towards the creation of the penitentiaries intended in 1776 to form a permanent substitute for transportation to America. Millbank Prison (q.v.) provided means for the confinement of every prisoner in absolute separation, according to the modern doctrine, and it was intended that his treatment should be on the most advanced reformatory system; but this experiment went no further at this time. In 1838 the existence of the terrible evils which attended the transportation system were formally established by the report of a commission, who said that the system was unequal, without terrors to the criminal class, corrupting to both convict and colonist, and very expensive, and they recommended punishment in penitentiaries instead.

Various improvements in the Millbank system were introduced after this, and finally in 1842 it took the form of passing the convicts through two stages of discipline in certain prisons at home before sending them to complete their sentences in one of the colonies. The first of these stages was passed in a prison in which each inmate was kept in complete separation and brought under influences by which it was hoped to lay the foundation of a reform in his character; the second in a prison in which he was employed in useful public works in regulated association, but confined in a cell by himself by night and at all times when not at work or in chapel. The complete efficiency of this stage was at first marred by a certain number of convicts being placed in association at night, but for some time past the separation has been thoroughly carried out, the only exception being in the cases of prisoners who on medical grounds cannot properly be left alone. The first stage was regulated according to the system adopted, first experimentally, at the new model prison at Pentonville which had been erected in 1842. When the experiment had been proved to be successful, convicts were sent to undergo it at Millbank Prison and at other prisons of which the construction was suitable.

In those early days of the formation of the convict system the confinement of prisoners in complete separation was regarded with great prejudice. This arose from the reports of its results in certain prisons in America, where it had been some years before carried out with the accompaniments of darkness, absolute solitude, absence of any employment, and unwholesome sanitary conditions. It was therefore decided after some experiments, and as a sort of compromise with the prejudices above referred to, that the period of separation should be limited to nine months. Since the date when this decision was arrived at much greater experience has been gained, and the unsoundness of the grounds on which this limitation was founded has been fully

demonstrated (see the Report of the Directors of Convict Prisons, 1887–88, and the accompanying report of an inquiry into the subject by the medical inspector). The whole of the prisons in the United Kingdom where sentences up to two years are carried out have gradually been remodelled on the separate system; and laws enacted recently in several foreign countries, after full investigation, permit of the isolation of prisoners under proper conditions for much longer periods. There is, therefore, no reason why the separate stage of a sentence of penal servitude should not endure for a period equal to that which may be passed in that condition under a sentence of imprisonment.

The second or public works stage was carried out in prisons like Portland, which was constructed for the purpose in 1847. Dartmoor Convict Prison was opened in 1850 for the same purpose, Portsmouth Prison in 1852, Chatham in 1856, &c. In these the convicts have been employed in large public works, in farming, &c. The breakwater at Portland, the fortifications of that island, the large extension of the dockyards at Chatham and Portsmouth, the forts which protect Chatham, and various other military and naval works, besides the construction of large prison establishments, attest the advantages of the system, which also enables the prisoners to gain a useful knowledge of trades by which they can obtain employment on their release, and affords a most useful reformatory influence in accustoming the prisoners to habits of industry.

From 1844, and more rapidly after 1852, the number of prisoners actually transported gradually diminished; most of those who received that sentence being discharged on free pardon in Britain after serving from half to two-thirds of their sentences. In the course of time the opposition of the Australian colonies to the continuance of transportation led to the abandonment of the system altogether, and since 1867 no convicts have been sent to those colonies. The punishment of penal servitude was by various acts passed between 1853 and 1864 substituted for transportation. These acts introduced certain notable modifications in regard to sentences of the next degree of gravity to capital punishment. When transportation was in force a prisoner on whom such a sentence was passed might be treated in any of three different ways. Commencing his sentence in the local prison, where he remained until it was thought proper to remove him, he might be transferred either (1) to Australia, from which in all probability he never returned, whatever the length of his sentence; (2) to Gibraltar or Bermuda, from which he was brought back to England when he had served a certain portion of his sentence, and there discharged; or (3) to the hulks, or to the 'public works' prisons substituted for them. If he went to Australia he was in the early days assigned as a servant to some free settler, and so at once ceased to be actually a prisoner; but in later years a system was established under which all prisoners first passed a certain time in a convict establishment and then were discharged conditionally to find employers for themselves. It also became the practice ultimately to retain all prisoners sentenced to transportation for a certain time in a prison in England, conducted on the separate system, from which they might be sent either to the hulks or to the 'public works' convict prisons which replaced them, or to one of the convict establishments abroad. If sent to the hulks or 'public works' prisons they might either remain there till discharged, or be drafted off to one of the convict establishments in the colonies. Whichever of these modes of disposing of the convicts was followed, in none of them did they pass the whole of their sentences in the condition of prisoners, a most important consideration to bear in mind. Those who were sent to Gibraltar or Bermuda, as well as those who did not leave the country at all, but were confined in the hulks, were released on free pardon after they had passed about half of their sentences or a little more. Those who went to Australia were released even sooner, but in their case only on certain conditions, by which a hold over them was maintained.

When the objections of the Australian colonies to the continuance of transportation thither made it necessary to adopt some other plan for disposing of these prisoners, the Penal Servitude Act, 1853, was passed in order to carry out a system founded on that which had been followed with regard to prisoners sentenced to transportation, but which provided for the large majority being retained at home. Under this act a sentence of transportation could not be passed for less than fourteen years, and a sentence of penal servitude was substituted for all lower terms. But the sentences of penal servitude permitted by this act were shorter than the sentences of transportation assigned to various crimes under the old acts, because it was intended that the whole of the sentences of penal servitude should be passed in confinement; the terms were therefore fixed so as to correspond with the periods which had actually been passed in prison by convicts who had been sentenced to transportation but not actually sent out of the country. For seven years' transportation or less was substituted four years' penal servitude; for over seven but not over ten years' transportation was substituted not under four years and not over six years; for over ten but not over fifteen years' transportation was substituted not under six years and not over eight years; for over fifteen years' transportation was substituted not under six years and not over ten years. No difference was made in life sentences. Power was taken in this act to release convicts in the United Kingdom conditionally or on ticket-of-leave, instead of releasing them as formerly on free pardon. It was not intended that this power should be exercised in the case of sentences of penal servitude, as they had already been shortened to the terms actually served in prison under the sentence of transportation, but only in the case of prisoners sentenced to transportation who were not actually sent out of the country. The convict prisons therefore contained inmates serving under different conditions: those under sentence of transportation might have a remission of part of their sentences if well conducted, those under sentences of penal servitude could get none.

Before long it was found that great disadvantage in training and reforming the convicts, and in managing them by appealing to better feelings than those of mere fear, arose from the absence in the case of prisoners sentenced to penal servitude of the hope of gaining a remission of sentence; and the comparison in this respect between these prisoners and others in the prisons who were under sentence of transportation gave rise to great discontent among the prisoners. The consequence was that in 1857 another act was passed which made the length of sentences of penal servitude the same as former sentences of transportation, and thus facilitated the application of the system of remission to sentences of less than fourteen years as well as to those above that term. The House of Commons Committee (1856), on whose report this course was adopted, also recommended the introduction of a shorter term of penal servitude intermediate between the highest term of imprisonment then in ordinary use and the lowest term of transportation or, as it had become, penal servitude. Accordingly the Act of 1857 authorised a sentence of not less than three years' penal servitude for any

offence which might be punished by seven years' transportation. In carrying out this act prisoners were allowed to gain remission of a portion of these short sentences as well as all the others.

About this time very warm discussions were being carried on on the subject of penal systems, originating partly no doubt in the great change necessitated by the gradual abolition of transportation; and about 1861–62–63 those who attacked the system which had actually been introduced were able to point to a recent increase of crime as a justification of their attacks on it, more particularly on the ticket-of-leave system. Great point was given to this feeling, and it was much intensified, by an outbreak of crimes of violence in the metropolis (garrotting), of which the number rose to eighty-two during the six months beginning June 1862, having been only sixteen in each six months from the beginning of 1860 to June 1862. The result was that a Royal Commission was appointed to report on the Penal Servitude Acts and the system adopted to carry them out. In consequence of the report of this commission in 1864 another Penal Servitude Act was passed, in which the government did not fully adopt the recommendations of the Royal Commission as above set forth, but they raised the minimum term of penal servitude from three years to five years, except in the case of those who incurred a second sentence of penal servitude, in whose cases seven years was the minimum term permitted. This latter provision was repealed by the Prevention of Crimes Act, 1879.

A review by the light of later experience of the grounds on which the recommendation of the Royal Commission was made cannot but lead to the opinion that the experience of the Act of 1857 had been too short to justify the formation of any sound opinion of its effects. As regards the outbreak of violence in the metropolis, this was without doubt, as subsequent events showed, the work of a small number of men who adopted that form of robbery (a very common feature in the history of crime), and when these men were arrested and received exemplary sentences the crime ceased altogether. The remarkable feature of the figures for 1856–63 was not that they were especially high in 1862–63, but rather the extraordinarily low level to which they had suddenly fallen in 1860, and from which they rebounded.

The directors of convict prisons in their recent annual reports had more than once referred to the anomaly peculiar to the United Kingdom by which no sentence was possible between two years—which was practically the limit of a sentence of imprisonment—and five years, which is the shortest legal sentence of penal servitude, and had expressed their opinion that it was desirable to re-introduce the power of sentencing to penal servitude for terms as low as three years, which existed from 1857 until the Act of 1864, and was abolished by that act in consequence of the report of a Royal Commission, founded, as the directors showed, on erroneous deductions from imperfect data. In 1891 an act was passed to allow of the sentence of three years being imposed in future. By the Act of 1857 power was given to the Secretary of State to release convicts conditionally before the expiration of their sentences. This system, known as the ticket-of-leave system, was at the time strenuously attacked, under the erroneous supposition that it first introduced a system of releasing prisoners before they had served their full sentences; but this, as has been already stated, they never actually had done. On the contrary, under the ticket-of-leave system they were in point of fact detained to serve in prison a larger part of their sentences than had been customary before. Moreover, under the new system, instead of being absolutely pardoned when released, they were subject to revocation of their licenses if they did not conduct themselves well, by which their abstention from crime was materially guaranteed.

The principle on which the system of punishment is founded is that those who are subject to it should suffer discipline of such degree of severity as may act as a deterrent to them and to others who might be tempted to become criminals, but that they should at the same time be brought under the reformatory influences of religious teaching, good example, and such training in self-control as can be given by offering certain advantages to industry and good conduct, as well as inflicting suitable punishment for the reverse. Every effort is made to prevent that mutual contamination which was such a serious blot on prisons of the old type, and those prisoners who have not been previously convicted and are on inquiry found clearly to be only beginners in crime are formed into a separate body, who, from the badge by which they are distinguished, are called the Star class, and who are kept strictly apart from all others. The mode of carrying out the sentence of penal servitude is as follows: Every convict who receives this sentence is placed for the first nine months in a prison in which his whole time is passed in a separate cell, except, of course, the time devoted to public worship, necessary exercise, &c.; but at all times he is so far as possible isolated from his fellows. The remainder of his time in prison is passed in one of the large establishments in which useful work is carried on in a regulated association, and he is able by industry combined with good conduct to earn a remission of nearly one-fourth of his sentence, besides gaining certain privileges in regard to letter-writing, visits from his friends, and such like indulgences, and a gratuity to be paid to him on his discharge. The practice which existed until 1864 of encouraging industry and good conduct by certain increases in the diet was discontinued from that date, as it was held that to allow a prisoner more or better diet than absolutely necessary led to undesirable contrasts with poor but honest folk who could afford no such indulgences; and it will easily be seen that this principle, which is of course applicable to other things besides diet, makes it very difficult to devise a suitable system of rewards for prisoners while retaining the necessary penal or restrictive conditions of prison life.

At the head of every convict prison is the governor, whose duty it is to administer and supervise all branches of the prison. He is assisted by a staff who have to control and regulate the discipline and employment of the prisoners, and a staff of clerks, who keep a record of all matters relating to the prisoners and their sentences, their conduct, &c.; and also by a steward or storekeeper, with a staff of clerks, who has the charge of stores and accounts. The chaplain conducts divine service, visits and advises the prisoners. He has under him schoolmasters, who conduct their education. A Roman Catholic priest is appointed to some prisons, and in them are collected all the prisoners of that communion. The medical officer has charge of matters relating to the health of the prisoners. The hospital is constructed on the most modern principles, and provides accommodation for some patients in separation and for the association of those for whom the medical officer thinks it necessary. To control and supervise these convict prisons a body called the Directors of Convict Prisons was created for England and Wales by statute in 1850, whose powers unite those of visiting justices of ordinary prisons with those of various bodies which had been created by parliament from time

to time to govern the various institutions thenceforward placed under their management—viz. Millbank Penitentiary, Pentonville Model Prison, Parkhurst Reformatory, the hulks, and the convict prisons at Portland, &c., by which the hulks were superseded. A similar body was created for Ireland in 1854, and there a system founded on and closely resembling that which had been developed in England was created; but until 1888 (when a convict prison was established at Peterhead in connection with the convict labour at the harbour-works) all male convicts sentenced in Scotland served the greater part of their sentences in convict prisons in England. The convict prisons are visited frequently by one or more of the directors, whose duty is to see that the governor and the other officers of the prison are doing their duty, to hear and determine reports of misconduct of prisoners of such gravity that the governor cannot deal with them under the powers vested in him, and to hear and determine any reports against the prison officers. To directors also the prisoners can complain or appeal if they consider they are not fairly treated, or bring forward any requests they have to make, but which the governor has no power to comply with. A body of gentlemen from among the magistrates is also appointed by the Secretary of State to act as independent visitors, and so form a further guarantee against abuses in the prison, and a channel by which any grievances felt by any prisoner can be brought forward.

Each day marks are awarded to every prisoner according to his industry, and these marks measure daily his progress towards attaining that remission of about a quarter of his sentence which he is allowed to earn, as well as towards his promotion to a higher class, in which he may enjoy certain privileges before referred to. The punishments inflicted on those prisoners who misconduct themselves consist of close confinement, sometimes in a semi-darkened cell, reduction of diet, and forfeiture of the privileges already earned, such as gratuity to be paid on discharge, periodical letters, visits from friends, &c., and forfeiture of remission, flogging with a 'cat' or a birch, which is awarded only in the gravest cases, such as assaults on warders, &c.

The cessation of transportation in 1867, and the consequent accumulation in the United Kingdom of all prisoners discharged on expiration of their sentences or on conditional license, instead of in a distant colony, might reasonably have been expected to increase the amount of serious crime, by the return of many of them to their former habits of life. As a matter of fact no such result has followed. On the contrary, the various influences which have been at work to check and repress crime, among which a well-regulated prison system may claim its due share, have enormously reduced the number of convicts under sentence.

About the beginning of the reign of Queen Victoria, when the population of England and Wales was about fifteen millions, there were 43,000 convicts in New South Wales and Van Dieman's Land, besides others in the colonial penal settlements, in the hulks at home about 3000 or 4000, several hundreds at Millbank, about 900 each at Bermuda and Gibraltar, or about 50,000 in all. By 1869 this large number was represented by 11,660 prisoners under sentence of penal servitude, of whom 9900 were males and 1760 females, and this number had been further reduced on March 31, 1891, to 4978—viz. 4654 males and 324 females. In Ireland there were 922 males and 403 females in 1869, and 434 males and 26 females in 1891.

The number of persons who have received sentences of transportation or penal servitude has diminished enormously. In the year 1837, 3785 persons were sentenced to transportation, and 4068 actually transported; in 1842, 4481 were sentenced and 4166 transported. In 1869 the number of persons in Great Britain whose crimes were so grave as to justify their being sentenced to penal servitude was 2219; this number has continuously fallen, till in 1889 it was only 1039, and in 1890 only 828; yet during the interval the population of Great Britain has risen from 25,529,184 to (1891) 37,740,283. In Ireland, with a population of about 5,500,000, in 1869 there were 191 sentences of penal servitude, and in 1889, with a population of about 4,700,000, there were 83 such sentences. Of the present convict prison population in England and Wales, 515 have been placed on the Star class. These are found practically to be of an entirely different stamp from the habitual prisoners. They are more easy to manage, more willing and industrious, and experience shows that but few of them come back to a convict prison on reconviction after their discharge.

As regards the health of the prisoners in convict prisons, the statistics show that the favourable conditions under which they are placed on account of the great attention to sanitary requirements, the regularity of their lives, and the constant medical care taken of them result in a low mortality of 10·5 per 1000 in an average of years; and this result is brought about in spite of a large proportion of the inmates of prisons being persons of low type, who have led dissipated and irregular lives. The conduct of the prisoners is, as a rule, very good, the result of a steady system of control under which exact discipline is enforced, and, while good conduct and industry are encouraged, misconduct is surely punished. The greater number of prisoners conform to the regulations so readily that either they do not incur any report or punishment of any kind, or at most commit some trifling breach of regulations; and in fact the great bulk of the prison offences are committed by a few habitual offenders against the rules.

The prisons in which sentences of imprisonment are carried out have a separate history from that of those which have been described. There were so far back as two centuries ago occasional protests against the abuses and cruelties practised in prisons, and a notable parliamentary inquiry into the misconduct of a gaoler named Bembridge was held in 1730; but until the last quarter of the 18th century the idea that prisoners had any claim for humane treatment had hardly made any way beyond the circle of a few philanthropic reformers; any attempt to use the period of imprisonment to improve the nature of the criminal was almost unknown. The way to better things was undoubtedly opened by Howard's visits of prison inspection about 1776, and in following years, and by his reports on the condition of the prisons he visited, followed as they were by proposals for reform and improvements which were enjoined and encouraged by acts of parliament. Solitary confinement with labour and instruction was approved by statute in 1774, and in 1784 general regulations were formed for the treatment of prisoners, among which a proper classification of prisoners according to the gravity of their offences was enjoined. In 1791 justices were enjoined to visit and inspect these prisons three times in each quarter, and to report on them to quarter sessions. In 1814 the appointment of chaplains was made compulsory. But compliance with these statutory reforms did not immediately follow, for indeed it was a long time before they passed into the stage of practical fact. In 1818 there still remained 518 prisons in the United Kingdom, to which more than 100,000 prisoners were committed in the year,

and only twenty-three of these had been subdivided so as to enable the above classification to be carried out. In fifty-nine of them the males were not divided from the females (and in fact there was no statutory injunction to this effect until 5 Geo. IV. chaps. 65 and 85). In 445 prisons there was no employment of any kind for the prisoners; in 100 of the gaols overcrowding was excessive; no less than 13,057 prisoners were crowded into the space which, according even to the moderate demands of those days, was fit for only 8545. The prisons were in many cases so ill-regulated that they became scenes of abandoned wickedness. In 1835 and 1839 most important legislative steps were taken. Further rules of administration were laid down in the acts passed in these years, and inspectors of prisons were appointed to see that they were carried out. By the latter act also the vital importance of a suitable design and construction for gaols as an aid to good prison management was recognised by the creation of the office of Surveyor-general of Prisons to advise in these matters.

Howard had advocated the complete separation of prisoners by placing each of them in a cell alone, and this was provided for in the Penitentiary Act, 1778. The practice was adopted in a few county prisons, and it was again enjoined together with daily divine service and the absolute separation of males from females in 5 Geo. IV. chaps. 65 and 85, but the expense of building these cells fortified a prejudice against the 'solitary' system, which was largely increased by the too thorough mode in which it had been carried out in America. A commission which was sent in 1834 to America to inquire into the matter, however, reported entirely in favour of the principle of separation if judiciously carried out. Their recommendation was followed in the construction of Pentonville Model Prison in 1842, and the success of the system led to an extensive reconstruction of county prisons on the same plan, finally resulting in that system being adopted to the exclusion of any other.

Although some progress in other respects followed the Acts of 1835 and 1839, there was still so much imperfection and such want of uniformity in rules, diet, labour, &c. that further reforms and stronger pressure on the local authorities in whom the management of the prisons was vested was urgently called for. These were provided by the Prison Act, 1865, which enacted a code of rules for all prisons, and required that each male prisoner should be provided with a separate cell.

In 1878 a further and most important step was taken by the transfer of the control and pecuniary charge of all the local prisons to the government, represented in each member of the United Kingdom by a body of commissioners appointed by royal warrant. This measure was justified by the impossibility of ensuring due uniformity in the treatment of prisoners in all gaols so long as they remained in the hands of so many independent local authorities, by the great difficulties, amounting to impossibility, in getting some of the local authorities to provide proper prison buildings, and by the unnecessary costliness which resulted from the existence of so many small and independent prisons; for there were still no less than 113 of these establishments in England and Wales, 57 in Scotland, and 38 (besides 95 bridewells) in Ireland. The consolidation which has resulted from them has made a very large saving in the cost of prisons. There are now only 58 local prisons in England and Wales, 15 in Scotland, and 22 in Ireland. In Scotland the geographical conditions have led to the adoption of a system of licensed cells under charge of the police, where prisoners under sentence not exceeding fourteen days may be retained. These are allowed in twenty-eight places to avoid the necessity of sending such prisoners long distances to serve a short sentence. The population of these little prisons is for the most part from one to two. In the years 1876–77, the last in which the prisons were under the local authorities, their cost in England, exclusive of new buildings and interest on loans, &c., was £495,068; in 1889–90 it was £320,381; and it has since fallen still further. The diminution would have been larger but that in various ways the service has been improved. Roman Catholic priests are now generally appointed and paid for their services; the clerical work formerly largely done by prisoners is performed by paid clerks; attention is more generally paid to the schooling, and more money expended on schoolmasters. These acts have also ensured substantial uniformity of treatment throughout the United Kingdom, because all rules are now made by the Secretary of State or Lord-lieutenant of Ireland.

Prisoners before trial form a separate class in the prisons, and are now subjected to no more inconvenience than is necessary to ensure security and due order and discipline in the prison. They may wear their own clothes and supply their own diet if they choose, have full opportunities of receiving visits from their friends and corresponding with them, and are not obliged to perform any unaccustomed or menial labour for themselves if they will pay for assistance.

Debtors also are kept apart from other prisoners. The rules made in the Prisons Act, 1865, with regard to this class of prisoner were no doubt framed in view of the practice of imprisonment for debt which had not then been abolished by law. But the act subsequently passed in 1869 made it possible to imprison only those debtors who refuse to pay when they have the means, and as this is a species of fraud they hardly deserve the consideration which, under the rules, is accorded to them. They are under no obligation to work, are allowed to lounge about in association, may provide their own clothing, bedding, and food, which may include wine and beer, and are allowed more frequent visits and letters from their friends than criminal prisoners.

The Prisons Act, 1865, also allowed the creation of a class of misdemeanants of the first division, who might be put in that class by the sentencing court; and the special sympathy accorded to sedition and seditious libel led to persons found guilty of these crimes being, by the law of 1877, secured in the privileges of this class. They are allowed a specially furnished room, and may provide their own clothing, bedding, and food, the services of an assistant to clean their rooms, and, on payment, full use of books, newspapers, &c., and certain privileges as to additional letters and visits at the discretion of the visiting committee. They are not considered criminal prisoners. Doubts have sometimes been expressed whether the power of making a distinction of this sort in the punishment awarded to different offenders has been wisely exercised. It would recommend itself to most people that such an offender as a clergyman, who is imprisoned for not conforming to the rubric, should suffer little or no punishment beyond the deprivation of liberty, but a fraudulent bankrupt, or one who committed a criminal assault, or who incited others to crime and violence, is not necessarily a proper object for similar consideration on the ground of his social position being higher than that of an ordinary typical criminal.

To pass from these special classes to the ordinary prisoners, the general rule is that after sentence every prisoner is permitted to raise himself progressively by industry, combined with good conduct, through four stages, in each of which he gains

some amelioration of his treatment. Commencing with penal or first-class hard labour—with sleeping on a wooden bed on which there is no mattress, and with great restrictions as to books, letters, and visits—he gradually gains an improvement in each of these matters, and in each stage accumulates a small sum, larger in the higher stages than in the lower, which is either given him or laid out for his benefit on his discharge. If in spite of these encouragements he still fails to conduct himself in conformity with the regulations, he may be subjected to punishment by deprivation of diet, confinement in a cell which is nearly dark, and in case of violence corporal punishment with a birch or a cat-of-nine-tails. The necessity for these punishments has, however, very largely diminished—a result of the system of progressive stages; for if ill-conducted or idle his progress into the higher stages is delayed, or he may be degraded into a lower stage after attaining to a higher. Comparing the number of dietary punishments in 1877 (the last year before the prisons were brought under the government) with the number in 1890, it is found that while the prison population has diminished by one-third, this form of punishment is less by one-half. Certain powers for the infliction of punishment reside with the governor, but corporal punishment or heavier sentences than he is empowered to award can only be inflicted by order of the magistrates who form the visiting committee of each prison, or by a commissioner.

The visiting committee are appointed every year by quarter sessions, about twelve to each prison. Their duty is to visit the prison periodically, to hear any complaints of the prisoners, to deal with reports made of the misconduct of any prisoners, and to fulfil certain other functions more particularly laid down in the rules made by the Secretary of State; but they have no authority over the officers. In fact, whereas up till 1878 the local authorities managed the prison, and the government inspected it, the position is now reversed, the government manages and the local justices inspect. A cardinal principle of the prison system is that every prisoner under sentence should be fully employed, but the description of employment varies in the different stages of the sentence. On first reception, and for a month at least, hard penal labour is exacted from everybody sentenced to hard labour, according to their strength and capacity. The tread-wheel or crank is the typical form of this 'first-class hard labour,' as it is called; stone-breaking, oakum-picking, and some other forms of labour are enforced in the case of prisoners who are unfit for the tread-wheel. After this industrial labour is allowed, according to the capabilities of the prisoner, and forms a relief from the dull monotony of the first-class hard labour. A large proportion of the prisoners supply the wants of the prison population by weaving, tailoring, &c., and the list of trades followed or articles made in the prisons enumerated in the annual reports reaches to about 150; but, as may be imagined, there is a large number of prisoners who know of no industry which can be followed in a prison cell, and great difficulty is found in providing them with work, for they do not generally stop long enough to learn a trade to any good purpose. Mat-making and matting-weaving, which was, it is believed, introduced many years ago as a prison industry, is a trade which is very easily learned; but the same reason which recommends it for prison purposes makes it appropriate for many charitable institutions, such as blind schools, &c., and enables free persons who are incapacitated for other work to find employment at it. These latter are naturally anxious to diminish the competition of prison labour in their trade, though it forms now an exceedingly small part of that which they have to contend with, for the product of machinery and foreign and colonial labour, besides the introduction of rival materials to serve the same object, far exceeds the output from the labour of prisoners in this country. The number of prisoners employed in this industry has, however, by the efforts of the prison authorities, been diminished from nearly 3200 to 747, whose work is, for the reasons given above and because of the necessary conditions of prison labour, probably not more than that of one-fourth or one-fifth the same number of free labourers.

Every prison has its medical officer, and a well-regulated and well-constructed infirmary. The death-rate has decreased from 10·8 per 1000 to 8·2 per 1000 in prisons in England and Wales. The absence of all diseases due to insanitary conditions is the main reason of the healthy condition of the prisoners; and no doubt the strict temperance—for no alcoholic liquors form part of the dietary—and the regular life contribute to this result.

In order that the standard of efficiency may be maintained in all the prisons, and that opportunities may be given to both officers and prisoners to communicate any complaints they may have to make, inspectors are appointed to visit each prison at least monthly, and to report to the commissioners on any point which may require their intervention. From the time when the prisons were taken over by the government in 1878 there has been a very large and almost uninterrupted diminution in the number of prisoners, who form the prison population. In June 1878 there were 21,030 prisoners, and the average number during that year was 19,818; in the prisons in England and Wales in June 1890 there were 14,122, and the average number of prisoners during the year 1890 was 13,495. It would be absurd to claim this result as all due to any change of prison management, but there can be no doubt that this has had its share in the result, just as in former years bad prison management was a potent cause of the increase of crime.

The indication of the diminution of crime which is afforded by these prison statistics is fully corroborated by those which are derived from other sources. It is found that during the fifteen years 1875–90, while the population has increased by about 25 per cent., the number of convictions for what is in ordinary language considered a crime—i.e. offences involving dishonesty, violence, &c.—instead of increasing in proportion with the population, has progressively diminished considerably. In England and Wales from 1880–85 there were 149,046 summary convictions annually, and from 1895–1900, 146,143 annually, a reduction of 16·9 per 100,000 of population. In the same periods there were 9962 and 7766 convictions on indictment respectively, showing a reduction of 33·8 per 100,000 population. But for the increase in the number of commitments for technical offences, which are rather offences against social discipline than crimes, the total number of commitments would have very largely diminished. The police returns show too that the number of the criminal classes has decreased by about 22 per cent., and the number of disorderly houses has shown a corresponding diminution.

The design and construction of a prison is, as may be supposed, a feature of the very first importance. Security is of course one of the essentials, but there are others almost as important. In looking over old prisons one cannot but be struck with the massiveness of construction of many of them —the huge bars and bolts, the large clumsy locks, the ponderous grated doors, and, sometimes chained to the wall, the heavy fetters with which the prisoners were loaded. In the old

prison at York, built under the inspiration of the Rev. Sydney Smith, part of which still exists, security is provided for by making the walls of the cells of a rough stone, some 6 feet square and 2 or 3 feet thick, and grated windows of massive iron exclude the light. By such means as this it was intended to ensure the safe custody of the prisoners without constant personal watchfulness and supervision by the prison staff. All this is changed in the prisons of more recent date, but the security is even greater than before, because in a prison of modern construction the supervision can be more thorough. In a prison of modern construction the site is surrounded by a wall about 18 feet high, outside of which, unless a road or street runs along the boundary, a margin of about 20 feet is left unbuilt on as a precaution against the facilities which buildings against a wall may give for scaling or breaking through it.

The prison is entered through two pairs of double gates, having a space between them sufficient for a wagon to stand in, so that the solid outer gate may be shut before the grated inner gate formed of iron bars is opened. At the side of the gate is the porter's lodge, and perhaps certain waiting accommodation and rooms in which the prisoners may, under supervision, receive visits from their friends. These gates give admission to the outer court of the prison. Opposite the gate is probably the entrance of the main building; the offices of the governor, chaplain, &c. are placed here. After passing these the buildings occupied by prisoners are arrived at.

Every prisoner occupies a cell measuring 13 feet by 7 feet, and containing 800 cubic feet of air, with a grated window, part of which is made to open; in the wall are inlets from a channel for fresh air, warmed when necessary by hot water pipes, and outlets for foul air drawn out through flues which communicate with a furnace and tall chimney in the roof. On shelves in the wall are the books and the small utensils provided for the prisoner's use. The furniture consists of a stool to sit on, a fixed table, a wooden bed board and a coir pillow, sheets, blankets, and rugs, and a mattress for the prisoners who have passed the first stage. In some cells a crank, or a loom, or such other fixed means of employment, is provided, and a bell-pull, by means of which a warder's attention can be called when necessary, and an eye-hole in the door through which the warder can inspect the prisoner.

Rows of cells such as this are arranged alongside each other, and on opposite sides of a corridor about 16 feet wide, which is open to the roof; and there may be above the ground-floor two or three tiers of cells, access to which is given by iron stairs and a gallery off which the cells open. There are possibly some cells on a lower level, where usually the heating apparatus and sometimes the cook-house, bakehouse, workshops, and stores are situated; but in the most recent constructions it is thought better to place these latter in separate buildings outside the block of cells. A hospital for sick patients is provided, and a separate block of cells in which prisoners are placed on first reception, and where they are cleansed and examined by the doctor, and their private property and clothes taken from them, the latter being replaced by a prison suit if the prisoner is convicted, or if before conviction he prefers not to wear his own clothes. There is a tread-wheel house in many prisons, and often a mill, which is worked by the tread-wheel, and which supplies flour or water for the prisoners' use. The department for females is put distant from that for males, and no male officer is allowed into the female division unless he is accompanied by a female warder or matron. Storerooms are provided where it may be most convenient, for the provisions, clothing, materials for manufacture, &c. The chapel is a prominent feature in the prison, for prayers are read before all the prisoners who can attend every morning, and on Sunday there are morning and evening services. In prisons built on this model towards the middle of the century the chapel was divided into little boxes, so as to isolate prisoners completely from each other. This construction has for some time been abandoned; it failed in its object, and in fact helped to prevent detection of an offender, while it was thought to diminish the influence of the minister and the effect of the service.

In connection with the offices is a library of selected books for issue to the prisoners, which is under the control of the chaplain. In some part of the cell block is a bath-house, where prisoners are required to wash themselves periodically; and in connection with the female side of the prison is a laundry for the washing of the prisoners' clothing, sheets, &c., and in which also sometimes washing is done for people outside on payment. There are also workshops in which carpenters, smiths, &c. can carry on their trades for the benefit of the prison. Large airy yards surround the blocks in which the prisoners live. In these they take their daily exercise under supervision of warders, pacing round and round a ring, separated by such an interval from each other as may prevent oral communication. Part of the space inside the walls is often cultivated for vegetables for consumption by the prisoners.

Since 1869 a new feature has been developed in controlling the criminal class. By an act passed in that year and revised in 1871, the latter being called the Prevention of Crimes Act, any person convicted on indictment a second time may be subjected to 'supervision' by the police for seven years after the expiration of his sentence. During this period he is required to report himself to the police once a month, and to keep them informed of his residence; he is also required to prove his innocence if certain suspicious circumstances are brought against him. If he fails to comply with the obligation to report himself he may be imprisoned for a year with hard labour. The convict released conditionally before the termination of his sentence is subject to similar obligations, and if there are reasonable grounds for believing that he is leading a criminal life, or showing himself unworthy of the freedom conditionally granted him, or if he should be actually convicted of crime, he may be returned to prison to undergo the whole of that part of his sentence which was remitted.

To aid in the work of detecting criminals a Habitual Criminal Register has been established, in which the names, descriptions, photographs, and criminal career of all persons who are proved to have been twice convicted on indictment are recorded. This register is printed and circulated to all police forces and prisons, and thus these authorities have at their command means of establishing the identification of any prisoner who comes into their custody, who is suspected to be an habitual criminal, and can ascertain what prison should be applied to for further evidence on the subject. In order to supply means of ascertaining whether any person in custody is on the register of habitual criminals, in cases where no special identity is suggested, a Distinction Marks Register has been established, in which all the peculiar marks, or other remarkable personal peculiarities of those who have been registered, are classified and recorded.

It will readily be understood that it would not accord with the modern theory of punishment combined with reformation to turn any prisoner adrift at the prison gate on completing his sentence, to

seek for means of earning an honest livelihood with all the disadvantages which his connection and imprisonment obviously entail upon him. The first statutory recognition that it was right and expedient to make some provision for prisoners on discharge was in 32 Geo. III. chap. 45, by which justices might convey any such person by pass back to his parish; and at the opening of the chapel of the New House of Correction for Middlesex, the chaplain, the Rev. Samuel Glasse, pointed out that, the discipline and training of the prison having it might be hoped supplanted the prisoners' habits of idleness and profligacy by habits of industry, the magistrates might be able to speak of them according to their merit or demerit to the parish officers. He observed, however, that this would not provide for the cases of Irish delinquents who had no settlement in the United Kingdom, but who were not few in number, as indeed they are not at this present day, when they furnish to British gaols an entirely disproportionate number of inmates. He thus showed the necessity for doing what in more recent times has been undertaken by societies for the aid of discharged prisoners. In 1823 the Gaol Act enabled a moderate sum of money to be paid for the benefit of discharged prisoners out of the rates, or from public benefactions belonging to the gaol, in order that they might resort to any place of employment or honest occupation. In 1862 societies for the aid of discharged prisoners received statutory recognition, and the money awarded by the justices for the assistance of any prisoner, to an amount not exceeding £2 per head, might be handed over to these societies for their benefit. This act was obviously a recognition of societies which already existed, but it afforded a great stimulus to the formation of others. The earliest of the existing societies, according to the list published by the Reformatory and Refuge Union, was the Hampshire Society, which dates from 1802; Dalston Female Refuge dates from 1805; the Sheriffs' Fund, which deals with City cases, from 1807. When the prisons were handed over to the government in 1878 there were about 30 discharged prisoners' aid societies acting in connection with the prisons, then 113 in number, and still numbering 66, even after the reduction which took place in the first two years.

The transfer of all prisons to the government in 1878 had a most important effect in adding to the number of those societies. The Prisons Act had been passed partly to ensure uniformity of treatment of prisoners in all localities, and those who advocated the claims of the discharged prisoner were not slow to perceive that the same principle might be made to apply to the system of helping them to obtain honest employment on completion of their sentence; and, further, that the difficulty they had met with in inducing many of the local authorities to provide funds, or in raising private subscriptions, might be overcome, now that the government was responsible, because they were virtually bound to continue the grants which had been made by many local authorities, and could not refuse to make similar grants in places where the local authorities had hitherto failed to do so. In connection with this the Commissioners of Prisons took action with a view to securing the proper appropriation to this purpose of many charities and benefactions devoted in former times to the assistance of prisoners, but the exact objects of which were no longer applicable to existing circumstances. These funds were more or less within the cognisance of the Charity Commissioners, and some of the largest of them had already been diverted to objects quite disconnected from prisons or prisoners; but by means of an act passed in 1882 steps were taken by which most of these funds have been appropriated for the benefit of discharged prisoners through the agency of the above-named societies. Since 1887 every prison in England and Wales has had a discharged prisoners' aid society working in harmony with it. The work carried on by these societies was found so satisfactory that in 1898 the Prison Commissioners issued a new scheme for their guidance, reorganising the system on which the grants in aid were given. At the same time the scheme did not in any way interfere with the voluntary work of the societies, beyond giving advice and grants of money. Male convicts who have served long sentences do not share in these grants, as the gratuity they can earn during their sentence is supposed to give them all the money aid they require if they wish to reform on being released. Two societies in London—the Royal and the St Giles Christian Mission—specially look after them. Female convicts share in the grant, and special provision for them is made at Aylesbury prison, on the same lines as the aid societies at local prisons. In 1899 further steps were taken, in the appointment of lady visitors to all prisons, by the sanction of the commissioners. These ladies co-operate with the prison officials and chaplains, and spare no trouble for the reformation of discharged prisoners or to find them employment. In 1900 the number of discharged prisoners who passed through the hands of the sixty-two aid societies was 39,413. These were assisted with money or clothes, provided with new employment, restored to former employment, sent to homes or other institutions, or aided in other ways; 2000 were unworthy of help, and 1100 refused assistance. The aid societies also take juvenile offenders under their special care. They are taken from the prison gates to the homes, are restored to their parents, provided with employment, or in some way or other helped into the paths of respectability.

United States.—In the early part of the 19th century the most advanced examples of prison discipline and construction were to be found in the United States, and although in the second half of the century this prominent position has not been maintained, the importance of the improvements initiated in America cannot be forgotten. Following closely on Howard's report, the 'Philadelphia Society for Assisting Distressed Prisoners' was founded in 1776—the first of the kind in the world; and, though dissolved during the war, it was reorganised in 1787, and is still at work. Large measures of reform were quickly secured: by 1790 the principle of separation was recognised, and in 1794 all convicts were separated and secluded; in the latter year, also, capital punishment was abolished in Pennsylvania for all crimes but murder in the first degree. It thus became necessary to devise some substitute for capital punishment. At the Eastern Penitentiary at Philadelphia, opened in 1829, the so-called 'Pennsylvania System' of permanent seclusion of convicts was carried out; the evil effects arising from the rigorous application of this principle have been already referred to in this article, and even at Philadelphia the system is not now strictly enforced, whilst in all the other American prisons what is known as the 'Auburn System'—silent labour in association by day, and separation by night—has been adopted. In the southern states prisoners are leased out to the highest bidders for the term of their sentences; but this system, which condemns the convicts to a slavery that is not modified even by considerations arising from personal ownership, is gradually being abandoned. The first place of detention for juvenile delinquents was opened at New York in 1825; the first reformatories on the cottage or family system were established in Ohio—for boys at Lancaster in 1858, for girls at Delaware in 1878.

In 1877 the Elmira (New York) Reformatory was opened, at which a now famous system has been adopted for the treatment of first offenders under thirty years of age; the principal features are indeterminate sentences, the classification of prisoners into three classes under the marks system, and discharge upon probationary parole, under supervision. The prisoners enjoy a luxurious dietary, and many indulgences are granted to induce them to work, so that the penal element of a sentence of imprisonment is entirely absent.

A grave defect alleged by American critics is that in the county gaols and other places of detention for those awaiting trial all such prisoners are compelled to associate in a common hall, with all the evils which follow as a necessary result. It is said also that politics to a large extent determine the selection of prison officials, many of whom are appointed simply for services rendered to their party; and that the interference of labour organisations has had a considerable effect in the direction of putting a stop to contract labour—in New York, to labour of any kind—in the prisons. It may be added that crime has increased in the United States in a ratio far in advance of the growth of population; in 1850 the prisoners represented 1 in 3442 of the population; in 1880 they were 1 in 855. In a country where so many earnest and capable penologists are at work, however, there is every reason to hope for an ultimate return to better methods.

Privateer, a ship owned by a private individual, which, under government permission, expressed by a Letter of Marque (q.v.), makes war upon the shipping of a hostile power. To make war upon an enemy without this commission, or upon the shipping of a nation not specified in it, is piracy. Privateering was abolished by mutual agreement among European nations, except Spain, by the Declaration of Paris in 1856; but the United States of America refused to sign the treaty, for reasons which are given in the article Paris (q.v.). It is doubtful, however, how far that abolition would stand in a general war, for privateering is the natural resource of a nation whose regular navy is too weak to make head against the maritime power of the enemy, especially when the latter offers the temptation of a wealthy commerce. It was usual for the country on whose behalf the privateers carried on war to take security for their duty respecting the rights of neutrals and allies, and their observing generally the law of nations. While not considered Pirates (q.v.) by the law of nations, they were looked upon as little better during the great wars at the end of the 18th and the beginning of the 19th century, and as a rule received but scant mercy at the hands of the regular services. In the wars of 1793–1814 many English privateers were afloat. But in the same period no less than 10,871 English ships, with over £100,000,000, were taken by French 'corsairs;' the Breton privateer Surcouf took, in two months of 1807, prizes worth £291,250. At the American Revolution the new republic fully realised the advantage of its position in preying on the mercantile marine of Great Britain; and in the war of 1812 British commerce suffered severely at the hands of American privateers, of which it was computed that some 250 were afloat. During the American civil war the Confederate cruisers were at first regarded in the north as mere pirates; and the Alabama Claims originated in the charge against Britain of allowing the departure of privateers from British ports. In 1870 Prussia made a decree in favour of creating a 'volunteer navy.' See ENEMY, NEUTRALITY, ALABAMA, BUCCANEER, CORSAIR, PIRATE, PRIZE; Norman, *The Corsairs of France* (1887); Gomer Williams, *The Liverpool Privateers* (1897).

Privet (*Ligustrum*), a genus of plants of the natural order Oleaceæ, containing a number of species of shrubs and small trees with opposite leaves, which are simple and entire at the margin; the flowers small, white, and in terminal panicles; the calyx slightly 4-toothed; the corolla funnel-shaped and 4-cleft; the stamens two, projecting beyond the tube of the corolla; the berries 2-celled. Common Privet (*L. vulgare*) is a shrub growing in bushy places and about the borders of woods in the middle and south of Europe, and in some parts of Britain, now also naturalised in some parts of North America. It has half-evergreen, smooth, lanceolate leaves; and berries about the size of peas, black, rarely white, yellow, or green. The flowers have a strong and sweetish smell; the leaves are mildly astringent, and were formerly used in medicine. The berries, which hang on the shrub during winter, have a disagreeable taste, but serve as food for many kinds of birds; they are used for dyeing red, and, with various additions, green, blue, and black. A rose-coloured pigment obtained from them is used for colouring maps. The wood is hard, and is used by turners, and by shoemakers for making wooden pegs. Privet, although not spiny, is much used for hedges, often mixed with some spiny shrub, or with beech. It bears clipping well, and grows well in the smoke of towns, also under the shade of trees. A number of species of privet are natives of different parts of the East, and some of them are now to be seen in shrubberies in Britain. Most kinds of privet grow readily from cuttings, but some of the more ornamental kinds are increased by grafting them upon the common or other more vigorous species. It has now been proved that the shrub the white wax insect of China deposits the wax on is *L. lucidum*. See WAX INSECT.

Privilege. For the privileges of counsel, see BARRISTER; for the privileges of parliament, see PARLIAMENT; for those of peers and ambassadors, see NOBILITY, AMBASSADOR; for privileged communications, see CONFIDENTIALITY, LIBEL; for the sacredness of the confessional, see CONFIDENTIALITY; see also ARREST, DEBT, SANCTUARY, SOVEREIGN.

Privy-council. Wherever a feudal system of government has prevailed it has been customary for the sovereign to summon, from time to time, a council of his barons or nobles to advise him in matters of state. This practice was adopted by feudal monarchs rather as a privilege than as a duty, since it gave them the means of enforcing from powerful feudatories an acknowledgment of their sovereign rights. The attendance of a baron at the court of his lord was a tacit admission of the suzerainty of the latter.

Under the early English kings the royal council was styled the *Aula* or *Curia Regis*. It consisted of the Chancellor, the Justiciary, the Lord Treasurer, the Lord Steward, the Chamberlain, the Earl Marshal, the Constable, and any other persons whom the king chose to appoint; the two archbishops belonged to it as of right; and the Comptroller of the Household, the Chancellor of the Exchequer, the Judges, and the King's Serjeants were occasionally present at its meetings. The authority of the curia was originally co-extensive with that of the king, in whom all the powers of government, judicial and administrative, were united; but its constitution gradually underwent a complete change. In the first place, a distinction came to be drawn between the body of the curia—the *magnum* or *commune concilium*, which was the germ of the modern parliament—and the *concilium assiduum*—a permanent committee of the curia, which was constantly and closely attached to the person of the king. Then the two councils were themselves subdivided. The Court *ad scaccarium*, or Court of Exchequer, which sprang from the *concilium assiduum*, took cognisance of affairs of finance, then of actions affecting the revenue, and lastly of civil suits generally. The Courts of King's Bench and Common Pleas—descended from the *magnum concilium*—respectively acquired their separate jurisdictions. These changes had been accomplished by the end of the reign of King John. They were merely successive delegations of the royal authority, and left the king's prerogative as the fountain of law unaffected. In spite, therefore, of the establishment of regular tribunals, the sovereign still continued to exercise judicial authority, if not personally, at least through the agency of his chancellor and of the council, whose jurisdictions, afterwards so clearly distinguishable, were originally united. In the time of Edward III., however, the Chancery was rapidly becoming a separate tribunal; and by the end of the reign of his successor its establishment as the great court of equity had been effected. The *concilium assiduum*, also, had become a separate assembly of royal officials, bound by a particular oath and paid a regular salary, equally distinct from the courts of law and equity and from the *magnum concilium*, and regarded with no little jealousy by them both.

From the accession of Richard II. to the end of the reign of Henry VI. the Privy-council were not merely the servants but the ministers of the crown, and acted as a check upon the royal authority. While in theory the king could choose and dismiss the members of the council at his pleasure, the exercise of this prerogative was in fact subject to various restrictions. Some of the officers of the state were members of the council *ex officio*. The two archbishops claimed to belong to it as of right. The presence of other ecclesiastics, with whom the papal was a higher authority than the royal, introduced a further element of independence, and the occasional efforts of parliament to wrest the appointment of privy-councillors from the king made his influence over the council still weaker. The Privy-council exercised its control over the royal authority in two ways. Sometimes it merely advised and recommended. A more powerful kind of check was the refusal of the chancellor to affix the Great Seal to any royal grant of which the council disapproved. The English sovereigns endeavoured to defeat the operation of this check by the use of a privy-seal, and by retaining the Great Seal in their own hands. But the privy-seal passed into the custody of a separate official, and by the middle of the 15th century the council had succeeded in bringing every royal grant under its own notice at each stage in the procedure necessary for obtaining it. In the time of Henry V. the council assumed the name of Privy-council, by which it is now generally known. Its functions were then partly administrative and partly judicial. The former included the control of matters of finance, the establishment of *staples*—i.e. markets in which alone certain commodities could be exposed for sale—the regulation of the statutes which limited freedom of commerce between different parts of England, and the preservation of the peace. The latter cannot be better defined than in the words of Mr Dicey: 'Whenever, in fact, either from defect of legal authority or from want of the might necessary to carry their decisions into effect, the law courts were likely to prove inefficient, then the council stepped in by summoning before it defendants and accusers.'

In the third or modern period of its history, which commenced when the Wars of the Roses were drawing to a close, the character of the Privy-council has undergone a variety of changes. The destruction of the feudal system, and the overthrow of the old ecclesiastical supremacy, reduced it to a position of absolute dependence on the crown. At the same time the power of the council as regards the people was greatly increased (1) by the subjection of particular places to its control—e.g. Ireland under Poynings' Act (1494), and the Channel Islands; (2) by the exercise of the right to issue proclamations; (3) by the erection of new courts under its supervision—e.g. the High Commission and the Court of Requests; and (4) by the extension of its judicial authority in the Court of Star-chamber (q.v.). The judicial powers of the Privy-council were, however, restricted by the Long Parliament (16 Car. I. chap. 10, sect. 3), and in the 17th and 18th centuries its functions as the adviser of the crown in matters of government and state policy were gradually usurped by the Cabinet (q.v.).

Present Constitution and Functions.—The list of privy-councillors now includes the members of the royal family, the Archbishops of Canterbury and York, the Bishop of London, the great officers of state, the Lord Chancellor, the Lord Chief-justice of England, the Lords Justices of the Court of Appeal, the President of the Probate, Divorce, and Admiralty Division, the law officers of the crown, the members of the Judicial Committee (see below), several of the Scotch judges, the Speaker of the House of Commons, the Ambassadors, some of the Ministers Plenipotentiary and Governors of Colonies, the Commander-in-chief, the First Lord of the Admiralty, the Vice-president of the Board of Trade, the Paymaster of the Forces, &c., and necessarily all the members of the cabinet. Members of the council are in their collective capacity styled 'His [or Her] Majesty's Most Honourable Privy-council;' individually each member is styled 'Right Honourable.' (The Lord Mayor of London, although styled 'Most Honourable,' is not a privy-councillor. See *Notes and Queries*, first series, iii. 496; iv. 9, 28, 137, 157, 180, 236, 284; ix. 137, 158.) Under the authority of letters-patent dated 28th May, 10 James I. 1612, privy-councillors take precedence after Knights of the Garter. Amongst themselves they take rank according to seniority of appointment when no other principle of classification is applicable in the individual instances. Privy-councillors are appointed by the sovereign without either patent or grant, and are subject to removal at his discretion. By the common law, the Privy-council, as deriving its whole authority from the sovereign, was dissolved *ipso facto* upon the demise of the crown; but, in order to prevent the inconvenience of having no council in being at the accession of a new prince, it was enacted (6 Anne, chap. 7, sect. 8) that the Privy-council shall continue for six months after the demise of the

crown, unless sooner determined by the successor of the deceased sovereign (cf. Stephen, *Comment.* vol. ii. p. 491). It is now understood that no members attend the deliberations of council except those who are specially summoned. In ordinary cases only the ministers, the great officers of the Household, and the Archbishop of Canterbury are summoned; but on some extraordinary occasions summonses are sent to the whole council. (Thus, on November 23, 1839, the whole of the Privy-council were summoned to Buckingham Palace to receive the Queen's announcement of her intended marriage with Prince Albert.) Meetings of council are usually held at intervals of three or four weeks at the sovereign's residence; and six privy-councillors at least, with one of the clerks of council, constitute a meeting of council.

A privy-councillor must be a natural-born subject of Great Britain. His duties are defined by the oath of office as follows: (1) to advise the king to the best of his cunning and discretion; (2) to advise for the king's honour and good of the public, without partiality through affection, love, need, doubt, or dread; (3) to keep the king's counsel secret; (4) to avoid corruption; (5) to help and strengthen the execution of what shall be resolved; (6) to withstand all persons who would attempt the contrary; and (7) to observe, keep, and do all that a good and true counsellor ought to do to his sovereign lord. The personal security of a member of the Privy-council was formerly safeguarded by several statutes repealed by 9 Geo. IV. chap. 31. Immediately on the decease of the sovereign the Privy-council assembles and proclaims his successor, the Lord Chancellor affixing the Great Seal to the proclamation. The members of the Privy-council are then re-sworn as council of the new sovereign, after which a privy-council is held, and the sovereign makes declaration of his designs for the good government of the realm, and subscribes the oaths.

The functions of the Privy-council in modern times depend on a great variety of statutes, and it is only possible here to give a brief and very general survey of the whole field. The subject is one full of confusion, partly because of the vast mass of detail which it involves, and partly because the long historical development which the Privy-council has undergone has borne its natural crop of legal fictions, anomalies, and technicalities. It will be convenient to divide our observations under four heads:

(1) *The Privy-council as synonymous with the Executive Government.*—It is a commonplace of constitutional law that the cabinet, which is the organ of the executive government, is quite unknown to the law. In theory the cabinet is only a committee or inner circle of the Privy-council, and the Privy-council is still the only instrument through which the sovereign can exercise his prerogative. But the theory no longer corresponds with the facts; the power is exercised by the cabinet alone, and the Privy-council is never consulted. This is the sense which must be attached to the statements that the 'sovereign in council' has wide authority in the colonies, can make and enforce laws in such colonies as have no representative assemblies, and can allow or disallow the legislative acts of such as do possess them. The case is the same with orders in council relating to blockades, reprisals, or embargoes. And, in harmony with these expressions, it is the regular course in acts of parliament conferring specific powers on the executive government to confer them in terms on the 'sovereign in council.' In such cases the mention of the council is purely formal, and if the power is exercised it will be by the ordinary government (cf. also 13 and 14 Vict. chap. 59, sect. 30). It may be added that, as the executive power is thus dependent on the authority of the legislature, so no executive act can be done, and no order in council can be made, which an act of parliament cannot override.

This is now a recognised mode in which the legislature delegates defined legislative functions to the executive; and it is on this principle that the Board of Trade, for example, can make regulations for carrying out the provisions of an act of parliament, though the act may simply state, 'It shall be lawful for Her Majesty by order in council' from time to time to make such regulations.

(2) *The Privy-council as a separate Department of State.*—As the *aula regis* was the mother of parliament and of the various courts of law, so the Privy-council has given being, in quite recent times, to several administrative bodies (such, for instance, as the Board of Trade and the Local Government Board), to which many of its own administrative powers have been transferred. The different stages or methods in this process of differentiation are curious. The Board of Trade, established on its present basis in 1782, was at first, and still is in name, a committee of the Privy-council; it is defined in the Interpretation Act, 1889, sect. 12, as 'the Lords of the Committee for the time being of the Privy-council, appointed for the consideration of matters relating to trade and foreign plantations.' But for all practical purposes it is a distinct department of state, controlled by a president, who is a member of the government. The Board of Health, created 1848, was ten years later superseded partly by the Home Office, partly by the Privy-council. In 1871 the Local Government Board was created, in succession to the Poor-law Board, and to it were transferred many duties formerly exercised by the Privy-council in relation to the public health, such, for example, as the appointment and control of public medical officers and the carrying out of the Vaccination Acts. In 1889 a new Board of Agriculture was established, and took over the powers of the Privy-council in connection with the Destructive Insects Act and the Contagious Diseases (Animals) Acts. Neither the Local Government Board, nor the Poor-law Board (which, created in 1847, ceased to exist, as we have already mentioned, in 1871), nor the Board of Agriculture was ever formally a committee of the Privy-council, but in each case a portion of the administrative functions of the council was transferred to the new department, and the historical connection is illustrated by the fact that in all these cases the Lord President of the council is named first in the list of *ex officio* members. The Committee of Council on Education, established in 1839, remains in a different position. It has not been completely detached from the Privy-council and erected into a distinct department of the administration; and the member of the government who presides over it is still known as the Vice-president of the Council on Education. But it is commonly called the Education Department, and its complete detachment would require little more than a change in the designation of its chief, and a clear delimitation of the power and responsibility of the Lord President and the Vice-president of the Council. The Vice-president of the Council is already virtually minister for Education.

In 1885 the Secretary for Scotland Act further transferred to the new secretary the powers and duties of the Privy-council in connection with the Board of Manufactures and the Public Health Acts so far as Scotland is concerned. The Secretary for Scotland was also entrusted with control over Scottish education, under the title of Vice-president of the Scotch Education Department, which is still nominally a standing committee of the Privy-council.

With regard to the administrative business which remains with the Privy-council as a separate department of state it must be remembered as a general principle that the work is actually done by permanent government officials, under the control of the Lord President of the Council, who is responsible to parliament and to the country. It is believed that this is substantially the case even when special committees are appointed by act of parliament for special administrative purposes. That the members of such committees are little more than advisers results naturally from the modern doctrine of ministerial responsibility. With this limitation, committees of the Privy-council exercise in many cases a delegated legislative power. For example, in the grant of charters to boroughs under the Municipal Corporation Act, 1882, every petition for a charter is referred to a Committee of Council, which has power to consider it, and to settle a scheme for adjusting the rights and liabilities of the existing local authority. Under the Medical Acts the Privy-council is entrusted with the supervision of the qualifications and the registration of medical practitioners; and kindred powers are conferred by the Pharmacy Act, 1868, and the Veterinary Surgeons Act, 1881. For the Committee of Council on Education, see EDUCATION. A Universities Committee of the Privy-council was constituted for England in 1877, and for Scotland in 1889 (see UNIVERSITIES).

The style under which administrative duties are imposed on the Privy-council varies. Sometimes it is referred to simply as the Privy-council; occasionally a clause is added that 'all powers vested in the Privy-council by this act may be exercised by an order in council made by two or more of the Lords and others of H.M. Most Honourable Privy-council' (Veterinary Surgeons Act, 1881, sect. 18). Sometimes the duty is laid upon 'the Lords and others of H.M. Most Honourable Privy-council, or any three or more of them of whom the Lord President of the Council, or one of H.M. principal secretaries of state for the time being, shall always be one' (9 and 10 Vict. chap. 96).

(3) *The Privy-council in its widest Comprehension.* —The Privy-council, as a body, has in modern times no regular duties at all, administrative or judicial. Membership of it is a coveted honour, conferring rank, precedence, and titular dignity. It cannot, however, be fairly described as obsolete or dead, and on rare and abnormal occasions it has exercised powers not falling strictly within the sphere of ordinary legislative or judicial authority. Thus, the Privy-council in 1788 took on itself the duty of inquiring into the sanity of George III. and receiving the reports of the royal physicians. In 1821 it determined the constitutional question of Queen Caroline's right to be crowned as Queen Consort. But in general it is a force kept permanently in reserve, apart from the working elements of the constitution. And, as the character of British constitutional growth has ever been the adaptation of old expedients to newly felt needs, the possibility remains that some unforeseen constitutional convulsion may recall this ancient and honourable body from its merely nominal dignity to at least temporary life and usefulness.

(4) *The Judicial Committee of the Privy-council.* —The most important of all the offshoots of the Privy-council is the Judicial Committee. Officially it is merely a committee. In essence it is a court of law, possessing a wide and (indirectly owing to its connection with the Privy-council) a peculiarly elastic jurisdiction, which includes appeals from the ecclesiastical courts, petitions for the extension of letters-patent for inventions, and, above all, appeals from Indian and colonial courts of law. The history of this last branch of the appellate jurisdiction of the Privy-council is exceedingly complicated, and we cannot enter upon it minutely here. Three distinct and conflicting theories have been promulgated upon the subject. (1) According to Pownall (*Administration of the Colonies*, 1774), when the necessity for an appeal from the decisions of the colonial governors, who, although not properly qualified lawyers, were yet called upon to preside in the courts of law, was clearly apprehended, the one precedent of a judicature within the realm possessing foreign jurisdiction which presented itself to the minds of the English sovereign and his advisers was that of the jurisdiction of the Privy-council over the Channel Islands. Since the time of King John (1204) appeals from the royal courts in Jersey and Guernsey—with the latter of which Alderney and Sark were for judicial purposes united—had been brought before the king and his council in England. Now the English sovereign claimed—a claim which the colonials acquiesced in, and which the House of Commons itself had tacitly admitted—that his colonial settlements and possessions were the demesnes of the crown, lying quite beyond the jurisdiction or cognisance of the state. The historical relation between the feudal duchies of King John and the royal plantations and possessions abroad being so intimate, no great effort of administrative imagination was necessary to make the analogy complete. Thus it came to pass that appeals from the courts constituted in the various colonies were taken not to the House of Lords, nor to the courts of law and equity, but to the king in council. (2) A second theory is suggested by Macqueen—viz. that the Privy-council originally entertained colonial petitions under the authority of a reference from the peers, and that, when the intervals, gradually becoming longer, between the sessions of parliament rendered this mode of redress unsatisfactory, the council came to discharge in their own right those functions which would have been delegated to them by the peers if parliament had been summoned. (3) The statute 25 Hen. VIII. chap. 9 appears to suggest a third explanation of the origin of the appellate jurisdiction of the Privy-council. Under that act, a subject aggrieved by the decision of any court in any part of the king's dominions might appeal to the king in chancery. Every such appeal was referred by commission under the Great Seal to the Court of Delegates, the decisions of which were, in spite of a distinct prohibition in a statute of Elizabeth, reviewed upon petition by the Privy-council. These theories relate to different periods of time, and thus, although apparently conflicting, are not necessarily irreconcilable. One central fact, the right of the sovereign to entertain an appeal from any colonial court, is undisputed and indisputable. We know that, in less than a century, the body to which the crown entrusted the *administration* of colonial affairs was repeatedly reconstituted, and there is no reason why the *judicature* for colonial appeals may not have undergone similar changes in the course of three centuries. The modern history of the judicial committee is well known. The statute 2 and 3 Will. IV. chap. 92 transferred to the king in council the jurisdiction of the Court of Delegates; 3 and 4 Will. IV. chap. 41 formally created the judicial committee, and vested in it all the judicial authority of the Privy-council, the Commissioners of Appeals in prize causes, and the Court of Delegates. The judicial committee comprises the Lord President of the Council, the Lord Chancellor, the Lords Justices, and such other members of the Privy-council at large as shall hold or shall have held certain judicial or other offices enumerated in the acts. By 34 and 35 Vict. chap. 91 Queen Victoria was empowered by order in council to appoint by warrant under her sign-manual four additional

paid judges, each being, or having been, a judge of one of the superior courts at Westminster or chief-justice of Bengal, Madras, or Bombay, to act upon the judicial committee. Under the Appellate Jurisdiction Act, 1876 (sect. 14), provision was made for the substitution of two additional 'lords ordinary of appeal' for the four paid judges appointed under 34 and 35 Vict. chap. 91, and thus for the ultimate merging of the judicial committee in the House of Lords.

The conditions of appeal from colonial courts to the Privy-council are prescribed, sometimes in the charters of justice constituting such courts, sometimes by colonial acts, usually by orders in council. The customary conditions are that the amount at stake should exceed a certain sum in value, that leave to appeal should be asked from the court below within a certain time after the date of the judgment appealed against, and that proper security should be found. It is, however, the inherent prerogative right, and on proper occasions the duty, of the King or Queen in council to exercise an appellate jurisdiction over *all* colonial courts and in all colonial cases, civil as well as criminal. In the exercise of this jurisdiction, and in the absence of any charter or statutory right, the Sovereign in council may grant special leave to appeal in *civil* cases of substantial, general, or constitutional importance, where the judgment appealed against was plainly wrong or attended with sufficient doubt to justify the judicial committee in recommending that it should be reviewed. The Sovereign in council will not, however, review or interfere with the course of *criminal* proceedings, unless it is shown that, by disregard of the forms of legal process, by some violation of the principles of natural justice, or otherwise, grave and substantial injustice has been done.

The decisions of the judicial committee are pronounced by one member of the committee only, and not, according to the usual practice in divisional courts, the court of appeal, and the House of Lords, by each of the presiding judges. The student of the Privy-council reports is unable, therefore, to tell whether or not their lordships are unanimous, and, if not, who constitute the majority.

The Lord President of the Council is the fourth great officer of state, and is appointed by letters-patent under the Great Seal. The office is very ancient, and was revived by Charles II. in favour of the Earl of Shaftesbury in 1672.

Scotland once had a Privy-council of its own, but it was merged in that of England by 6 Anne, chap. 6. There is a separate Privy-council for Ireland, which in 1891 consisted of fifty-eight members, who are sworn pursuant to a sign-manual warrant directed to the Lord-lieutenant.

Wheeler, *Privy-council Law* (1894).

Privy-seal. See SEAL.

Prize. Prize-money, property captured from an enemy; but the term is generally applied exclusively to property taken at sea. As between the belligerent powers themselves the property in a ship or other thing captured passes at once by the mere capture to the captor. Up to the close of the Crimean war all property of an enemy even when carried in a neutral ship was liable to capture, as also was the property of a neutral if captured on board a belligerent ship. This involved a claim to the right of searching neutral ships, a claim which Britain was only able to enforce during the great war with France in consequence of her mastery of the sea; it was a right, however, which was continually being disputed, and the enforcement of it in the case of American ships led repeatedly to difficulties with the United States. When the treaty of Paris was signed in 1856 it was universally agreed that private property in neutral bottoms so long as it is not contraband of war should no longer be liable to capture (see NEUTRALITY, ENEMY, BLOCKADE). Army prize-money is distributed according to the provisions of the Army Prize Act of 1832; a list of those entitled to share being sent to Chelsea Hospital, whose treasurer makes the distribution. In naval cases, a ship taken must be sent to a port belonging to the capturing power, where the Court of Admiralty, on full evidence, adjudicates whether she be lawful prize or not. If the decision be affirmative the prize is then sold; or, if a ship-of-war, a certain allowance is granted by the state. The produce of the sale or grant is lodged in the hands of the Accountant-general of the Navy, for distribution to the officers and men who assisted at the capture. The net produce of the sale or grant is first divided rateably among any ships (if there be more than one) concerned in the capture. If under the orders of a flag-officer, he receives one-thirtieth part of the whole; the commanding officer then receives one-tenth part of the remainder, or of the whole if no flag is present; or, if there is more than one ship present, one-tenth part is divided between the commanding officers. After provision has thus been made for the flag (if any) and for the portion of the commanding officer or officers, the remainder of the proceeds is so distributed that each officer, man, and boy shall receive shares or a share: commanders and officers of similar rank receive forty-five shares each; lieutenants and officers of similar rank, from forty shares to thirty according to seniority; sub-lieutenants, &c., twenty shares each; midshipmen, &c., twelve shares; naval cadets, ten shares; chief petty officers, twelve shares; first-class petty officers, ten shares; second-class petty officers, seven shares; able seamen, four shares; ordinary seamen, two shares; and boys, one share each. Warburton's *Prince Rupert* (vol. iii.) gives an interesting distribution of prize-money in the 17th century.

Prjevalski. See PREJEVALSKI.

Proa (Malay *prahu*), sometimes known as the 'flying proa,' is a peculiarly-shaped canoe in use by the natives of the Malay Archipelago, and on the China Seas, especially by the Ladrone islanders. It is about 30 feet in length by 3 in width, and has the stem and stern equally sharp, so as to sail backward or forward without being turned round. One side is flat, and in a straight line with the stem and stern; the other side is rounded, as in ordinary boats. This peculiar formation would make it liable to be easily upset, were it not for a framework which projects

Proa.

to windward, supporting a weight which counterbalances the pressure of the wind on the sail. The sail resembles the ordinary lug-sail, and is formed of mat. Slight variations from this form are found, but the principle of construction is the same.

Probabilism. See CASUISTRY.

Probabilities, CHANCES, or the THEORY OF AVERAGES. To assign a number which measures the probability of a future event may at first seem impossible; and yet the whole business of many large companies instituted in every civilised country for the 'insurance' or 'assurance' of lives, &c. is mainly based upon the methods of assigning such a number. When it is certain that a future event will take place, or will not take place, a fixed number is selected for each case to indicate that then the probability amounts to certainty: and these two measures are the limits of our scale. Will the sun rise to-morrow morning in the east? Probability = 1, certainty in favour. Will full moon be seen to-morrow morning in the east? Probability = 0, certainty against. Between these two limiting numbers, 0 and 1, lies the number (a proper fraction) which measures the probability of any undecided event. The number, then, by which we mark the chance, or expectation, or probability of anything occurring in the future, must be a fraction like $\frac{3}{4}$, $\frac{6}{13}$, $\frac{113}{365}$, or ·273, and can never be so large as 1, which was fixed as the higher limit, certainty: and by the fractional number assigned to any event we can readily compare its probability with those of other future occurrences.

To assign the proper fraction to any future event will, in general, imply knowledge of a large number of similar events. Thus, in January, what is the probability that on next 12th April the sun will rise bright and unclouded? Relying on the constancy of nature and the doctrine of averages, we consult the calendars and weather-notices of the last 50 years, say, and find that in 17 of these the result was favourable and in 33 unfavourable. On these data the probability required is $\frac{17}{50}$, rather over $\frac{1}{3}$. In other words, the odds are nearly 2 to 1 against the event. The fraction $\frac{33}{50}$ measures or shows the probability that the event will *not* happen. More generally, if any future event may occur in 12 ways and fail in 15 ways, then the probability of its occurring is $\frac{12}{12+15} = \frac{4}{9}$; and the probability of failure, $\frac{15}{12+15} = \frac{5}{9}$. In such a case the 27 ways are supposed to have each the same chance of occurrence: and, since the event must either happen or fail, the sum of the two probabilities = certainty—i.e. $\frac{4}{9} + \frac{5}{9} = 1$. Thus, if $\frac{4}{9}$ is the chance of an event, $1 - \frac{4}{9}$ = chance that it will not occur. In a certain town only 4 days of May—taking the average of many years—are rainless: what will be our chance of finding next 15th May rainless? Chance = $\frac{4}{31}$: and $1 - \frac{4}{31}$ = chance of having rain. The principle involved in such simple solutions is the foundation of the mathematical treatment of chance or probability. Of all the occurrences, all equally possible, which relate to a future event, if a are favourable and x unfavourable, then $p = \frac{a}{a+x}$, where p stands for probability of the event occurring. Sometimes it is easier to find the probability of the event failing, and subtract that result from 1 as in the examples just given.

Out of 100 sailors who mutinied there were 10 ringleaders. If 2 are selected by lot for capital punishment, find the chance that both will be ringleaders. The total number of pairs is $\frac{100 \cdot 99}{1 \cdot 2}$, and the number of pairs among the ringleaders is $\frac{10 \cdot 9}{1 \cdot 2}$. Hence chance required $= \frac{10 \cdot 9}{1 \cdot 2} \div \frac{100 \cdot 99}{1 \cdot 2} = \frac{1}{110}$; i.e. the odds are 109 to 1 against the event. A bag contains 5 sovereigns and 4 shillings: if a child is asked to draw three coins at random, what is the probability that 2 will be sovereigns and 1 a shilling? Here the total number of groups of 3 which can be formed out of all the 9 coins is $\frac{9 \cdot 8 \cdot 7}{1 \cdot 2 \cdot 3}$, or 84, which forms our denominator. Of the sovereigns there are $\frac{5 \cdot 4}{1 \cdot 2} = 10$ pairs, each of which may be drawn with each of the 4 shillings, giving 40 groups of 3, which forms our numerator. Hence chance required is $\frac{40}{84} = \frac{10}{21}$; i.e. the odds are 11 to 10 against the event.

Sometimes actual trial seems to throw discredit on the mathematical measure of a chance. Thus, if a die be thrown, the chance of a 5 or any other number turning up must be $\frac{1}{6}$ by our definition: whereas a person may cast a die, say 20 times in succession, with the result: ace, 4 times; 6 and 4, each 3 times; 2 and 3, each 5 times; 5 not at all. How then explain the mathematical estimate? Simply that 20 is much too small a number to take an average from, and the result 'chance = $\frac{1}{6}$ for each side of the die' refers to the most general case possible—i.e. a very large number or even an infinite number of throws. Register for 10,000 throws, then for 100,000 or 1,000,000, and the results would more and more approximate to the mathematical result, and prove that each side has chance = $\frac{1}{6}$ — the die being of course a perfect cube.

An important extension of the theory is that the probability of two independent events *both* occurring is measured by the product of their separate probabilities. Thus, if A's chance of passing a certain examination is $\frac{4}{5}$ and B's $\frac{15}{16}$, then (1) the chance that *both* will pass is $\frac{4}{5} \times \frac{15}{16} = \frac{3}{4}\frac{5}{2}$—i.e. the odds are 7 to 5 against; (2) the chance that *both* will fail is $(1 - \frac{4}{5})(1 - \frac{15}{16}) = \frac{5}{1}\frac{5}{4}\frac{5}{4}$; (3) the chance that A passes and B fails is $\frac{4}{5}(1 - \frac{15}{16}) = \frac{1}{3}\frac{1}{6}$; and (4) the chance that A fails and B passes is $(1 - \frac{4}{5})\frac{15}{16} = \frac{2}{4}\frac{5}{8}$. By comparing these four results we see that the last event is the most probable of all, the odds being 25 to 24 in favour of it. Moreover, these results exhaust the possible alternatives of double event, therefore the four probabilities should together amount to certainty: and $\frac{3}{4}\frac{5}{2} + \frac{1}{1}\frac{5}{4}\frac{5}{4} + \frac{1}{3}\frac{1}{6} + \frac{2}{4}\frac{5}{8} = \frac{1}{1}\frac{4}{4}\frac{4}{4} = 1$, *Q.E.D.*

By the same principle we solve many useful and curious problems. A town-council of 20, 12 Liberals and 8 Conservatives, have to choose a deputation of 5 by ballot: find the probability that it will contain 3 Liberals and 2 Conservatives. Total number of groups of 5 is $\frac{20 \cdot 19 \cdot 18 \cdot 17 \cdot 16}{1 \cdot 2 \cdot 3 \cdot 4 \cdot 5}$, or $19 \cdot 3 \cdot 17 \cdot 16$, which forms our denominator. Number of groups of 3 from the Liberals is $\frac{12 \cdot 11 \cdot 10}{1 \cdot 2 \cdot 3}$, or $2 \cdot 11 \cdot 10$, and number of pairs of the Conservatives is $\frac{8 \cdot 7}{1 \cdot 2}$, or $4 \cdot 7$; therefore, multiplying $2 \cdot 11 \cdot 10 \cdot 4 \cdot 7$ = total number of groups of 5 which fulfil the conditions; and required probability is $\frac{2 \cdot 11 \cdot 10 \cdot 4 \cdot 7}{19 \cdot 3 \cdot 17 \cdot 16}$, or $\frac{385}{969}$. In other words, the odds are 584 to 385, or more than 3 to 2 against the event.

When a person buys lottery tickets his chance of success is found as in our opening paragraphs, and if multiplied by the value of the money attainable the product is called his 'expectation.' In this connection may be noted an important distinction

between the moral and mathematical values of 'expectation,' owing to the assumption that in such speculations the loss of money paid for tickets is not to be regarded. If one man of moderate means risks £500 in order to gain £5 when the odds are 100 to 1 in his favour, and another risks £5 to gain £500 when the odds are 100 to 1 against, the speculation in the former case appears much more reckless and immoral than in the latter, although in both cases the stake is exactly equal to the expectation.

We now reach the most important of all the applications of the theory of probability, its use in the calculation of life insurances and annuities. During the early part of the 18th century the celebrated London mathematician De Moivre constructed a formula of great simplicity which is still available, although largely superseded by elaborate 'tables of mortality' which have since been compiled in all commercial countries. By De Moivre's hypothesis, out of 86 children born at the same time 1 dies every year until all are extinct. Thus, for a man 40 years old, $86 - 40 = 46$, 46 years on an average are still before him and 45 others; and his chance of life is the average number between 0 and 46—i.e. $\frac{1}{2} \times 46 = 23$. Generally a person's probability of life or expectation is $\frac{1}{2}(86 - n)$, where n is the present age. Actuarial writers have found that this simple formula agrees with their official tables, except in the case of young children and aged persons. The tables are based upon long-continued observations of the mortality in the class of persons dealt with, and from them the theory of probability is easily applied in calculating annuities, reversionary payments, and other results.

For ascertaining the various life contingencies the Institute of Actuaries employ a table giving all the ages from 10 upwards, and, beginning with 100,000 persons alive at the age of 10, place opposite each succeeding age the number of survivors, till at 98 years none are left. At 40, survivors = 82,284; at 50, survivors = 72,726; therefore the chance that a man of 40 shall live to 50 is $72,726 \div 82,284 = .884$. The Belgian tables give .832 for the same event in the case of a married man living in town; and if his wife is 30 years old her chance of surviving for ten years is .862. These data give the following calculation of the chances of the four double events occurring 10 years hence:

Both being alive	.832 × .862	= .717
Both dead	(1 − .832) × (1 − .862)	= .023
Husband alive only	.832 × (1 − .862)	= .115
Wife alive only	(1 − .832) × .862	= .145

As we have seen already the sum of these four probabilities must = 1, which verifies the reckoning. The chance of both these persons being alive is evidently more than $\frac{7}{10}$—i.e. the odds in favour are better than 7 to 3.

Some of the higher applications of the doctrine of probability require a knowledge of the infinitesimal calculus, and are of interest only to experts. It is proved, for example, by integration and the theory of averages that the mean latitude of *all* places north of the equator is 32·704°; and when four points in the circumference of any circle (radius = r) are taken at random, the mean area of the quadrilateral so determined is $\frac{3r^2}{\pi} = r^2 \times .955$.

There are works on the subject by De Morgan (1837), Boole (1854), Todhunter (1865), Venn (1866), Whitworth (1886), and Procter (1887).

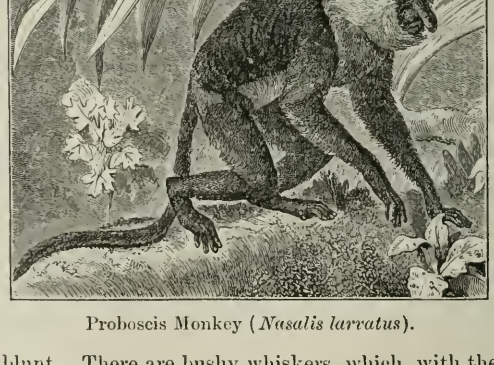
Probang, an instrument of various shape and material, for pushing obstructions down the œsophagus of a choking animal. See CHOKING.

Probate Court, a court created in England in 1858, in lieu of the old Prerogative Courts, to exercise jurisdiction in matters touching the succession to personal estate. Since the Judicature Acts of 1873–75 the Probate Court is included in the Probate, Divorce, and Admiralty Division of the High Court of Justice. If a man at his death leaves a will, then it must be produced and verified so as to prove that it is an authentic will, duly executed and signed in presence of witnesses, and therefore that the right to the personal estate is vested in the executors named by the will. The will is proved in common form by depositing it in one of the registries of the court, by making affidavit of the amount of the property, and by paying the probate duty (varying from £1 per £50 to £3 per £100, according to the amount of the property). The executors receive a copy of the will, accompanied by a grant of administration; and this probate copy is usually shown to bankers, &c. when the executors lay claim to the property of the deceased. If the authenticity of the will is disputed it must be proved by witnesses in court. If there is no will the personal estate devolves on the next of kin and widow, if any; and it is necessary that an application be made to the court to appoint an administrator. This is called taking out administration, and the act of the court appointing administrators is called letters of administration. See Dixon on *Probate* (2d ed. 1885).

Probationer, one who is on probation; especially, in Scotland, a divinity student who, having completed his studies and performed the prescribed exercises, is licensed to preach by the presbytery, and is entitled to become a candidate for a pastoral charge.

Proboscidea. See ELEPHANT, Vol. IV. p. 291.

Proboscis Monkey (*Nasalis larvatus*), a native of Borneo, one of the dog-like (Cynomorph) Catarrhines, nearly allied to the genus Semnopithecus. The nose is very long, especially in the old males, and is mobile and retractile like a proboscis. In the young monkeys it is short and



Proboscis Monkey (*Nasalis larvatus*).

blunt. There are bushy whiskers, which, with the long hair on the back of the head, encircle the neck. The colours—brown, red, yellow, and gray—are bright. The adult males are about 3 feet in height; the body is lank, and the tail is very long. In habit these animals are arboreal and gregarious.

Probus, MARCUS AURELIUS, emperor of Rome, was born at Sirmium, in Pannonia, early entered the army, and had the good fortune to attract the favourable notice of the Emperor Valerian. His subsequent conduct justified his rapid promotion, for he greatly distinguished himself on the Danube, and in Africa, Egypt, Asia, Germany, and Gaul. By the Emperor Tacitus he was appointed governor

of the Asiatic possessions of Rome; and such was the zealous attachment evinced for him by his soldiers that on the death of Tacitus they forced him to assume the purple; and, his rival Florianus having been removed, Probus was enthusiastically hailed emperor by all classes (276 A.D.). His brief reign was signalised by brilliant and important successes; the Germans were driven out of Gaul, and the Barbarians from the Rhætian, Pannonian, and Thracian frontiers; and Persia was forced to agree to a humiliating peace. The external security of the empire being established, Probus devoted himself to the development of its internal resources. But fearing that the discipline of the army would be deteriorated by inactivity, he employed the soldiers as labourers in executing various extensive and important works of public utility. Such occupations, considered as degrading by the soldiers, excited among them the utmost irritation and discontent; and a large body of troops engaged in draining the swamps about Sirmium murdered their excellent emperor in 282.

Process Engraving. See ILLUSTRATION, PHOTOGRAPHY.

Procession of the Holy Spirit. See SPIRIT, CREEDS.

Processions, as solemn and religious rites, are of very great antiquity. With the Greeks and Romans they took place chiefly on the festivals of Diana, Bacchus, Ceres, and other deities; also before the beginning of the games in the Circus; and in spring, when the fields were sprinkled with holy water, to increase their fertility. The priests went at their head, bearing images of the gods and goddesses to be propitiated, and started either from certain temples or from the Capitol. Among the Jews certain processions around the altar were—and still are to a certain extent—usual on the Feast of Tabernacles; and from them the Mohammedans have adopted their mode of encompassing the sanctuary seven times at Mecca. Processions also form a prominent part of the Buddhist worship. The practice was early introduced into the Christian church, but seems to have been adopted by Chrysostom at Constantinople to counteract the influence of the Arian processions through the streets to their churches outside the walls. Ambrose speaks of them as ancient in his day. During the middle ages processions were arranged on a scale of great magnificence, as at the Corpus Christi Festival. Since the Reformation they have been much less elaborate, especially in mixed countries; but at Vienna, and still more at Munich, the Corpus Christi procession is still magnificent. Processions are either Supplicatory processions or Cross processions, and are either directed to a certain distant place, to some miraculous image or object, or they are confined to the streets of the cities and the churches. Banners, crosses, and images are generally carried in front; the clergy follow; and the people make up the rear, singing hymns or reciting prayers. Processions to beseech the special mercy of God are variously to be described as *Litaniæ*, *Rogationes*, *Stationes*, *Supplicationes*, and *Exomologeses*; and again, they are to be distinguished as being with or without the Blessed Sacrament, relics, or images of the Virgin or Saints. Some are extraordinary and specially arranged; others are ordinary and fall under the common ritual, as those on Candlemas, Palm Sunday, St Mark's Day, three Rogation days, and at funerals. The Processional is the service-book containing the prayers, hymns, and ceremonial of processions. There is no doubt that, whatever their general intrinsic value, they offer in many instances one of the most strikingly picturesque features of the Roman faith, and that they answer a certain instinctive craving of the multitude. Processions through the streets are frequent in modern life as political and social demonstrations, as during strikes and the like, and, when not decreed dangerous to order or obstructive to traffic, are claimed as a privilege of free-born citizens; and they have been introduced to break the quiet of many English towns and villages as part of the peculiar warfare of the Salvation Army. For extensive pilgrimages, as such, their history and rites, see PILGRIM, MECCA, FESTIVALS, &c.

Prochein Ami. See INFANT.

Pro'cida, an islet of Italy, between the island of Ischia and the mainland (Cape Miseno), 50 miles W. by S. of Naples. Area, 1½ sq. m.; pop. 13,131. On its shores is the city of the same name, with a harbour, a royal palace, a state-prison, and a marine school. The people fish coral, tunny, and sardines, and grow fruits, wine, and oil. The island was occupied by Britain on two or three occasions between 1799 and 1813.

Proclamation, a public notice given by the sovereign or governing power to the people. The power of issuing proclamations is part of the prerogative of royalty as the fountain of justice. They sometimes consist of an authoritative announcement of some matter of state, or act of the executive government affecting the duties and obligations of subjects. The demise of the crown, and accession of a new sovereign, a declaration of war, and the issue of new coin are all occasions on which a royal proclamation is issued. In time of war, the crown by a proclamation may lay an embargo on shipping, and order the ports to be shut. But the most usual class of proclamations are admonitory notices for the prevention of offences, consisting of formal declarations of existing laws and penalties, and of the intention to enforce them; such as the proclamation against vice and immorality, formerly read at the opening of courts of assize and quarter sessions in England. In Scotland proclamations summon the Scottish peers to elect representatives to the House of Lords.

Proclamations are binding when they enforce the execution of laws already in being. Towards the end of Henry VIII.'s reign it was enacted that the king's proclamation should have the same force as an act of parliament; but this ill-judged law was repealed in the first year of Edward VI. It is now clear that the sovereign can neither make a new law, nor dispense with the existing law, unless by consent of parliament. A meeting which is proclaimed is not thereby rendered illegal; the proclamation is only a notice that, in the opinion of the government, the meeting is likely or certain to assume an illegal character. Proclamations are issued under the Great Seal, and are read aloud by heralds or other royal officers in the three capital cities of the United Kingdom; the reading is prefaced with the cry of 'O yes' (Fr. *oyez*, 'hear').

Proclus, the Neoplatonist, called the SUCCESSOR (*Diadochos*), i.e. of Syrianus, as the head of the Athenian school, was born in Constantinople about 411 A.D. He was of Lycian origin, and received his first instruction at Xanthus, in Lycia. He then studied at Alexandria under Arion, Leonaras, Hero, and especially under Heliodorus, with whom he applied himself chiefly to Aristotelian and Platonic philosophy. From thence he went to Athens, where a certain Plutarch, a philosopher, and his daughter, Asclepigeneia, a priestess of Eleusis, became his instructors, chiefly in theurgic mysteries. The vivid imagination and enthusiastic temperament which in his childhood already had led him to believe in apparitions of Minerva and Apollo, naturally convinced him, when all the influences of the mysteries were brought to bear

upon him, still more of his immediate and direct intercommunication with the gods; and he came to distinctly believe himself one of the few chosen links of the Hermaic chain through which divine revelation reaches mankind. His soul had, he thought, once lived in Nicomachus the Pythagorean, and, like him, he had the power to command the elements to a certain extent, to produce rain, and to temper the sun's heat. The Orphic Poems, the writings of Hermes, and all the mystical literature of that occult age were to him the only source of true philosophy, and he considered them all more or less in the light of divine revelations. That same cosmopolitan spirit in religious matters which pervaded Rome towards her end had spread throughout all the civilised pagan world of those days, and Proclus distinctly laid it down as an axiom that a true philosopher must also be a hierophant of the whole world. Acquainted with all the creeds and rites of the ancient Pantheons of the different nations, he not only philosophised upon them in an allegorising and symbolising spirit, as many of his contemporaries did, but practised all the ceremonies, however hard and painful. More especially was this the case in the severity of his fasting in honour of Egyptian deities—a practice, which, if it fitted him more and more for his hallucinations and dreams of divine intercourse, on the other hand more than once endangered his life. Of an impulsive piety, and eager to win disciples from Christianity itself, he made himself obnoxious to the Christian authorities in Athens, who, in accordance with the spirit of religious intolerance and fanaticism which then began to animate the new and successful religion against which Proclus waged constant war, banished him from this city. Allowed to return, he acted with somewhat more prudence and circumspection, and only allowed his most approved disciples to take part in the nightly assemblies in which he propounded his doctrines. He died in 485, in his full vigour, and in the entire possession of all those mental powers, for which he was no less remarkable than for his personal beauty and strength.

As to his system, some modern philosophers have exalted it to an extent which his own writings scarcely warrant. Victor Cousin holds that he has concentrated in it all the philosophical rays which emanated from the heads of the greatest thinkers of Greece, such as Pythagoras, Plato, and Aristotle. The predominant law of development is *triadic* in character. The existence of what is produced in that which produces it, its emergence from it, and its return to it (*μονή, πρόοδος, ἐπιστροφή*) are the three moments, by the continued repetition of which the totality of things is developed from their origin. The final source of this development is the original essence, elevated above all being and knowledge, between which and the intelligible there intervenes an intermediary member—the absolute unities (*αὐτοτελεῖς ἑνάδες*), together forming the single supernal number. Next to this comes the three spheres of the intelligible, the intellectual-intelligible (*νοητὸν ἅμα καὶ νοερόν*), and the intellectual. The chief property of the first is being; of the second, life; of the third, thought. Of these spheres the first two are again divided into three triads each, and the triad again into hebdomads, each separate member regarded as a divinity. The soul is made of three kinds of part-souls—divine, demonic, and human. Of these the divine fall into three orders: the four triads of hegemonic gods, an equal number of gods free from the world (*ἀπόλυτοι*), and the gods within the world, who are divided into star-gods and elementary gods. The demons are divided into angels, demons proper, and heroes. The soul enters temporarily into the material body, but it does not create matter, which comes directly from the unlimited —with the limited and the mixed, the components of the first intelligible triads. Space he considers as a body consisting of the finest light, which body penetrates that of the world. He distinguishes the principle of unity or divinity in the soul from thought or reason. It is capable by divine illumination of mystic union with the Deity. Indeed, faith alone is essential to the attainment of Theurgy, which, comprising mantic and supernatural inspiration, is preferable to all human wisdom; and in this Proclus chiefly differs from Plotinus, with whose system he agrees in most other respects.

There is no edition of the complete works of Proclus, but that of Victor Cousin (6 vols. 8vo. Paris, 1820) contains the *Commentaries* on the *First Alcibiades* and the *Carmenides*, and the treatises *De Libertate, Providentia, et Malo* (in a Latin translation); his second edition (1 vol. 4to, 1864) contains in addition to these the *Hymns*. Thomas Taylor, 'the Platonist,' published in 1788–89 translations of the *Commentary on Euclid*, with the Life by Marinus; the Six Books on the *Theology of Plato* in 1816; the *Commentaries* on the *Timæus* in 1820; the *Fragments* on the Lost Writings in 1825; *On Providence*, and *On Evil*, in 1833. The *Commentarius in Platonis Timæum* (ed. by Schneider, Breslau, 1847) was the one among his treatises that Proclus esteemed most highly. See Zeller's *Philos. der Griechen* (3d ed., 1881, iii. 2), and other books named under NEOPLATONISM.

Proconsul, a Roman magistrate not holding the consulship, who was invested with powers nearly approaching those of a consul, not, however, extending over the city and its vicinity. The proconsul was, at first, one who had held the office of consul, whose *imperium* was prolonged to enable him to bring an unfinished campaign to a close. The duration of the office was a year. During the later period of the republic, when the consuls were expected to spend the year of their consulate at Rome, they were generally appointed at its close to undertake, as proconsuls, either the conduct of a war in some province, or its peaceful administration. Occasionally the office of proconsul, with the government of a province, was conferred on a person who had never held the consulship. Under Constantine parts of certain dioceses came to be governed by proconsuls.

Procop. ANDREW, the Hussite leader, was born in 1380. Originally a monk, he served under Ziska, and on Ziska's death became commander of the Taborites. It was under his command that the fearful raids into Silesia, Saxony, and Franconia were carried out (see HUSSITES), and he repeatedly defeated German armies. He and his colleague, Procop the Younger, headed the internal conflict of the Taborites with the more moderate Calixtines; and in the battle with the Bohemian nobles at Lipan, near Böhmischbrod, on the 30th May 1434, both the Taborite commanders fell.

Procopius, the most eminent of the Byzantine historians, was born at Cæsarea, in Palestine, towards the close of the 5th century, and, having studied law, was taken by Belisarius in his train when he led the Roman armies against the Persians (526 B.C.), the Vandals in Africa (533), and the Ostrogoths in Italy (536). He appears to have displayed remarkable practical as well as literary talent, for he was on two occasions placed at the head of the commissariat. Returning to Constantinople shortly before 542, he was highly honoured by Justinian, and appointed prefect (if it was this Procopius) of the metropolis in 562. His death occurred, it is thought, about three years later. Procopius's principal works are his *Historiæ* in eight books (two on the Persian war, from 408 to 550; two on the war with the Vandals, from 532 to

546; and four on the Gothic war, going down to 552); *De Ædificiis*, or six books on the buildings executed or restored by Justinian; and *Anekdota*, or *Historia Arcana*, a sort of *chronique scandaleuse* of the court of Justinian, in which the emperor, his wife Theodora, Belisarius, *his* wife Antonina, and other distinguished persons, are depicted in the darkest colours. The most valuable of these productions is undoubtedly the first, in which Procopius writes with the clearness and fullness of knowledge that might be expected of a man who had been an eye-witness of much of what he narrates, and who had occupied a position that fitted him to thoroughly understand what he had seen. He is the principal authority for the reign of Justinian. The best edition of his complete works is that by Dindorf (1833–38). See Dahn, *Prokopios von Cäsarea* (1866); a work by Renan, *Essais de Morale* (3d ed. 1867); Haury, *Procopiana* (1891).

Procrustes (Gr. *Prokroustēs;* from *prokrouein*, 'to beat out,' 'to stretch out'), the surname of a celebrated robber of Attica, named Damastes, or Polypemon. All who fell into his hands he placed on a bed which was either too long or too short for them, but to which he adjusted them either by racking or by amputation till they died. This he continued to do until Theseus overpowered him, and made him suffer the tortures he had inflicted on others.

Procter, Bryan Waller ('Barry Cornwall'), was born in London, 21st November 1787. Educated at Harrow, with Byron and Peel for schoolfellows, he was articled to a solicitor at Calne, about 1807 came to London to live, and in 1815 began to contribute poetry to the *Literary Gazette*. In 1816 he succeeded by his father's death to about £500 a year, and in 1823 married Basil Montagu's stepdaughter, Anne Benson Skepper (1799–1888). He had meanwhile published four volumes of poems, and produced a tragedy at Covent Garden, whose success was largely due to the acting of Macready and Kemble. He was called to the bar in 1831, from 1832 to 1861 was a metropolitan commissioner of lunacy, and died 4th October 1874.

His works, issued under the pseudonym 'Barry Cornwall' (a faulty anagram of his real name), comprise *Dramatic Scenes* (1819), *A Sicilian Story* and *Marcian Colonna* (1820), *The Flood of Thessaly* (1823), and *English Songs* (1832), besides memoirs of Kean (1835) and Charles Lamb (1866). The last is always worth reading; but his poems may be safely neglected by the student of poetry, for they rarely are more than studied if graceful exercises, harmonious echoes of bygone and contemporary singers; in Mr Gosse's words, 'his lyrics do not possess passion or real pathos or any very deep magic of melody, but he has written more songs that deserve the comparative praise of *good* than any other modern writer except Shelley and Tennyson.' Yet 'Barry Cornwall' will be remembered as the man whom every one loved—that every one including a hundred of the greatest of the century: Lamb, Wordsworth, Coleridge, Leigh Hunt, Keats, Landor, Scott, Tennyson, Browning, Matthew Arnold, Swinburne, Hazlitt, Macaulay, Carlyle, Dickens, and Thackeray were only a few of his numberless friends and acquaintances.

See *Bryan Waller Procter: an Autobiographical Fragment* (1877), edited by Coventry Patmore; an article thereon in the *Edinburgh Review* for April 1878; the critical introduction by Mr Gosse in Ward's *English Poets* (2d ed. 1883); and a long obituary of Mrs Procter in the *Academy* for 17th March 1888.

Adelaide Anne Procter, Barry Cornwall's daughter, was born in London, 30th October 1825, and died there 3d February 1864, having in 1851 become a Roman Catholic. By her *Legends and Lyrics* (1858–60), first written some of them for *Household Words*, she won no small poetical renown.

Proctor, or Procurator, one who acts for another. This name was formerly given to a class of practitioners in the English Admiralty and ecclesiastical courts; but proctors are now merged for almost all purposes in the general body of solicitors. The King's or Queen's Proctor is an officer (now the Solicitor to the Treasury) who intervenes to oppose a petition for divorce if he has reason to suspect fraud or collusion. The clergy appoint proctors to represent them in the convocation of their province.

In each of the universities of Oxford and Cambridge there are two proctors, whose duties are to preserve the peace of the university, to repress disorders among the students, and inflict summary academical punishment. They have the command of the academical constabulary, and have also an extensive police jurisdiction in the town. They patrol the streets after dark, attended by officers popularly known as 'bull-dogs.' The proctors must be Masters of Arts, and are chosen by the colleges according to a certain rotation. They nominate two pro-proctors to be their deputies and assistants. The summary authority of the proctors extends both to undergraduates and Bachelors of Arts. They vote in the election of some of the professors and other officers. At Durham also there are two proctors, who, however, do not personally patrol the streets, and have command over only the university police.

Proctor, Richard Anthony, astronomer and popular author, was born at Chelsea in March 1834. He was educated first at King's College, London, and then at St John's, Cambridge, where, however, he devoted himself chiefly to athletics. He graduated in 1860 as twenty-third wrangler. His first literary venture was, in 1865, an article on 'Double Stars' in the *Cornhill Magazine*, and from that time he devoted himself to astronomy. In 1866 he was elected an F.R.A.S., and in 1872 its honorary secretary, but he retired in 1873 to make a lecturing tour in America. About this time he communicated to the R.A.S. some important papers on 'The Construction of the Milky Way,' 'The Transit of Venus,' 'Star Distribution,' &c.; and his name is associated with the accurate determination of the rotation of the planet Mars, and with the theory of the solar corona. One of his undertakings was the charting of the 324,198 stars contained in Argelander's great catalogue. His science magazine *Knowledge* was founded as a weekly in 1881, and became a monthly in 1885. He died at New York, September 12, 1888. He was a man of untiring energy, and, although the author of fifty-seven books, he found time to cultivate music, and was a great chess and whist player. His most important work was in connection with stellar distribution. As an author and lecturer he succeeded in interesting in astronomy a large public in America and the colonies as well as in England.

Among his works are *Saturn and its System* (1865), *Handbook of the Stars* (1866), *The Constellation Seasons* (1867), *Half-hours with the Telescope* (1868), *Other Worlds than Ours* (1870), *Star Atlas* (1870), *Light Science for Leisure Hours* (1871), *The Sun* (1871), *The Orbs around Us* (1872), *Essays on Astronomy* (1872), *The Expanse of Heaven* (1873), *The Moon* (1873), *The Borderland of Science* (1873), *The Universe and the coming Transits* (1874), *Our Place among Infinities* (1875), *Myths and Marvels of Astronomy* (1877), *The Universe of Stars* (1878), *Treatise on the Cycloid* (1878), *Flowers of the Sky* (1879), *The Poetry of Astronomy* (1880), *Mysteries of Time and Space* (1883), *The Universe of Suns* (1884), *The Seasons* (1885), *Other Suns than Ours* (1887), *Old and New Astronomy* (nearly completed in MS. at his death, and published 1888–90).

Procurator-fiscal, a legal officer in Scotland at whose instance criminal proceedings are taken in the local and inferior courts. He is appointed by the sheriff with the approval of one of the principal secretaries of state, and is not removable from office except for inability or misbehaviour, on a report by the Lord President and the Lord Justice-clerk. His business is to take the initiative in the prosecution of crimes. There being no coroner's inquest in Scotland, he does the work which that functionary does in England by way of inquiry into the cause of deaths occurring under circumstances of suspicion. Whenever he has reason to believe a crime has been committed his duty is to apply for a warrant to arrest the alleged criminal, to summon and precognosce witnesses, and to bring the case to trial. If the procurator-fiscal is informed of a crime which he thinks was either not committed, or of which there is no evidence satisfactory, he gives his concurrence merely to the private party who suggests it, but does not himself initiate the proceeding. When the procurator-fiscal takes the precognitions of the witnesses, he sends a copy of them to the crown counsel, of whom the Lord Advocate is the chief; and if these counsel think the evidence is strong enough, and warrants more than suspicion, the prosecution is proceeded with to trial.

Professor, an officer in a university, college, or other seminary, whose duty it is to instruct students, or read lectures on particular branches of learning. In the early times of universities the degrees conferred on students were licenses to act as public teachers; and the terms Master, Doctor, and Professor were nearly identical in signification. As, however, the body of graduates ceased in the course of time to have any concern in public teaching, a separate class of recognised teachers sprang up, paid sometimes with salaries, in other instances by fees from their hearers. These were called professors; and in the German and Scottish universities they became the governing body, and sole recognised functionaries for the purpose of education. In the universities in which collegiate foundations prevailed, as Oxford and Cambridge, they became, on the other hand, only secondaries or auxiliaries, attendance on their lectures not being generally deemed indispensable, and the necessary business of instruction being carried on by the functionaries of the several colleges. See UNIVERSITY, and the articles on the several universities.

The word professor is occasionally used in a loose way to denote generally the teacher of any science or branch of learning, without any reference to a university. It has been assumed as a designation not only by instructors in music and dancing, but by conjurors, athletes, and the like.

Profit-sharing was defined in a resolution of the Paris International Congress on Profit-sharing in 1889 as 'a voluntary agreement under which the employé receives a share, fixed beforehand, in the profits of a business.' It is argued and held to be proved by those in favour of the system, that profit-sharing advances the prosperity of an establishment by increasing the quantity of its product, by improving its quality, by promoting greater care of implements and economy of material, and lessens the risk of strikes, labour disputes, and the antagonism generally between capital and labour. Upwards of fifty British firms with 11,000 employés had by 1890 adopted some method of profit-sharing. Over eighty-one industrial establishments in France, Alsace, and Switzerland are working on a somewhat similar principle. Upwards of twenty-nine firms in the United States have also tried the experiment. In some of the native banks at Shanghai, every employé down to the lowest coolie has a share in the annual division of profits. Profit-sharing has been tried by firms of painters and decorators; paper, cotton, and woollen factories, &c.; and the famous *Bon Marché* in Paris. The additional fund thus coming to the workman may be paid to him directly in cash, or it may be put to his credit with a view of securing him a share in the capital of the firm, or it may be a deferred benefit for sickness and old age. The management of the business, as a rule, still remains in the hands of the capitalists.

Turgot in 1775 recognised a principle of profit-sharing, but Edme-Jean Leclaire (q.v.), a successful Parisian painter and decorator, was the first to carry it to a practical issue. He began by paying extra wages to his work-people, bonuses were then given to a few, a provident society was established which was succeeded by a distribution of profits. Leclaire by wonderful energy and capacity had risen to the front rank in his trade, and became a large employer of labour. For the benefit of his workmen he had established a mutual aid society in 1838, which he found to be 'a powerful means of moralisation and a living course in public law.' Having thus provided for the sick, as a master who had himself been a workman he remembered their hopeless condition when too old for work. He read everything he could lay his hands upon which tended to help him to improve the social condition of his workmen. M. Frégier in 1835, when making inquiries as to the condition of his workmen, suggested the participation of the workmen in the profits of the master as an expedient for doing away with the antagonism between capital and labour. There is evidence that M. Frégier did not afterwards believe in his own solution. Leclaire himself at first rejected it, and it was much later, he says, 'through cudgelling my brains, that in 1842 the thing appeared to me possible and one of the simplest to put into practice.' He had endeavoured gradually to educate his workmen up to the same point, and in January 1842 he pledged himself to this course. The men were still sceptical as to Leclaire's intentions, until an object-lesson in the shape of a bag containing £490 in coin was thrown on a table before them in February 1843. In the years 1842–47 an average of £750 was annually divided amongst eighty persons. The sum received was in proportion to annual earnings. In 1869 a deed was drawn up which stipulated that the net profits of the business should be divided into a certain fixed proportion between the managing partners, mutual aid society, and the regular workmen. Between 1842 and 1872 the mutual aid society and his workmen had received £44,000; down to 1882 the sum had reached £133,045. In 1870 the number who participated was 758, the dividend to workmen being £2465, or 14 per cent. on annual wages; in 1882 the sum of £9630 was divided amongst 998 persons. In 1884 the number was 824, the sum distributed being £9200, or about 24 per cent. on wages; in 1889 the amount was £9120. Five per cent. on the capital of 400,000 francs is, like the wages, deducted from the gross profits in order to find the net profits. Of the net profits 50 per cent. goes to labour in cash, 25 per cent. to management, and 25 per cent. to the provident society, which has now become half owner of the capital of the firm. The effect of all this on the workmen has been to make them sober, thrifty, and industrious. Other painters and decorators in Paris followed suit. When called a philanthropist, the founder said: 'I am simply a business man. I would rather gain 100,000 francs

and give away 50,000 than gain 25,000 and keep the whole for myself.'

The Co-operative Paper Works, Angoulême, founded by M. Laroche-Joubert, adopted a system of profit-sharing in entire independence of Leclaire. The dividend is payable in cash; provision is made for the admission of workmen shareholders, and by 1890 one-fourth of the shares were in their hands. The workmen have no part in the management. In the years 1879–88 the sum distributed over and above wages was £44,880.

In Messrs Godin's iron-foundry, Guise, employing about 1600 hands, the workmen's share of profits accumulates towards the purchase of shares in the firm. The first method adopted was that of the bonus; then the system of benefit societies; and for many years payments in cash. In 1880 the sum paid in interest on workmen's capital was £9200, and in wages £75,000; the number of workmen participating was 550; in 1889 the number was 961. M. Godin said that 'ever since the system was established the workmen are interested in improving the output; they are quick at pointing out sources of loss and defect, and they exert themselves to make new suggestions.' Mr Lowry Whittle, in his report to the Board of Trade, says that out of a squalid, ignorant peasantry M. Godin has produced an industrial community with the discipline of a regiment and the commercial alertness of the market-place. Since 1881 M. Piat, of the iron-foundries at Paris and Soissons, has distributed a portion of net profits. In M. de Courcy's plan 5 per cent. of the profits are set aside every year to form a fund upon which every employé, after twelve months' service, has a claim in the proportion of his year's salary to the total amount of profits set aside.

But those who have tested any system of profit-sharing declare that it requires much time and pains to produce substantial results; and a difficulty in working the system is that profit-sharers are not unfrequently unwilling to share the losses of the concern. In France there was founded in 1878 a society for facilitating the practical study of the different kinds of profit-sharing, which issues a quarterly *Bulletin de la Participation aux Bénéfices*. Both on the Continent and in America there have been experiments made in co-operative farming, fishing, market-gardening, and co-operative workshops. Alfred Dolge, of Dolgeville, New York state, a Saxon by birth, the largest manufacturer of felt shoes and piano felt, &c., in the United States, has in operation a system of what he calls earning (not profit) sharing amongst his employés, which originated in the conviction that in the creation of wealth certain of the employés contribute a larger share than is represented by their wages, and are entitled to something more than the wages proper. These real earnings can be determined by book-keeping, irrespective of any market-rate of wages. He claims that it is the selfish interest of every employer, as a means of actual ultimate gain, to find out what the earnings of each of his workmen are. The main features of the Dolge scheme are: a pension scheme, insurance endowment, and various benevolences. (1) Under the pension scheme a workman over 21 years of age, and under 50, after ten years' service, in case of partial or total inability to work, is entitled to a pension at the rate of 50 per cent. of wages earned during the year preceding; rising to 100 per cent. after twenty-five years' service. The pension fund is paid from yearly contributions set aside by the firm on behalf of each workman, and in 1891 it was reported that it would soon be self-supporting. (2) Fifteen years of service entitles to three insurance policies of $1000 each: 75 policies of a value of $138,000 were existing in 1891. Over $20,000 had been paid in premiums by the firm. (3) The endowment money is the sum credited each year on account of more work done than has been paid for in wages; the endowment account begins after five years' service, and is payable at the age of 60 or at death. Mr Dolge, for the benefit of his work-people, has given a park of 400 acres, assisted in building houses, maintains a club-house and free library, and pays $5000 a year to the school society. Strikes and labour disputes are reported as unknown at his factories.

In Great Britain any system of profit-sharing is not of such long standing as in France. The system adopted at the Whitwood Collieries of Messrs Briggs, Yorkshire, lasted beneficially from 1864 to 1875, when it ceased on account of the participation of the workmen in a strike against reduction of wages. During that time £34,000 had been distributed in percentage on wages. This percentage was paid when the net profits exceeded 10 per cent. on the capital embarked, one-half going to the work-people in proportion to earnings. Provision was also made for the work-people securing shares when the concern became a limited liability company.

The method of profit-sharing employed by many British firms may be gathered from the first rule which is generally adopted. 'From and after the 1st of September 18— the surplus (if any) of the clear profits of the business, beyond such definite sum as is for the time being reserved to the firm for their own benefit, shall be divided into two equal parts; one thereof to be distributed (not of legal right, but gratuitously) as a bonus to the employés in the manner defined by these rules, and the other to be retained by the firm.'

See Leroy-Beaulieu, *Répartition des Richesses* (1881); Hart's *Maison Leclaire* (1883); Taylor's *Profit-sharing* (1884); Wright's *Profit-sharing* (Boston, 1886); Böhmert's *Participations aux Bénéfices* (1888); Gilman's *Profit-sharing* (1889), which contains a full bibliography; Bushill's *Profit-sharing Scheme*, with list of British profit-sharing firms; *Die gerechte Verteilung des Geschäftvertrags* (1891); Rawson's *Profit-sharing Precedents* (1891); articles by Schloss in *Contemporary Review* for 1890; *The Just Distribution of Earnings*, an account of Dolge's scheme (1890); the report to the Board of Trade by J. Lowry Whittle (1891); Bushill's *Profit-sharing and the Labour Question* (1892); and the articles Co-operation, Socialism.

Prognostications. See Almanac, and Meteorology, Vol. VII. p. 155.

Programme Music. See Music, Vol. VII. p. 360.

Progreso, the port of Merida, in Yucatan, from which it is 25 miles N. by two lines of railway. It stands on an open bay, exposed to every wind, and is one of the worst harbours in the world; but it has a very large export trade in henequen.

Progression, in Arithmetic, is the succession, according to some fixed law, of one number after another. A series of numbers so succeeding one another is said to be 'in progression.' Progression may be of various kinds, but the three forms of most frequent occurrence are *Arithmetical Progression* (q.v.), *Geometrical Progression* (q.v.), and *Harmonical Progression*. If the terms of an arithmetical progression be inverted they form a series in harmonical progression; thus, 1, 2, 3, 4, 5, 6, &c. is an arithmetical progression; and 1, $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{4}$, $\frac{1}{5}$, $\frac{1}{6}$, &c. is a harmonical progression. This series is principally important in connection with the theory of music, in determining the length of the strings of instruments. See Harmonics.

Progression, Musical. The regular succession of chords or the movement of the parts of a

musical composition in harmony, where the key continues unchanged, is called Progression; where a new key is introduced it is not progression, but Modulation (q.v.).

Prohibition. See LIQUOR LAWS, and TEMPERANCE.

Projectile is the name given to any mass thrown so as to describe a path in air near the earth's surface. The path described is called the trajectory. The importance of the subject springs from its close connection with Gunnery (q.v.). Any mass projected into the air is under the action of two forces: first, its weight, acting downwards and practically constant; second, the resistance of the air to motion through it, which resistance is a function of the speed, and depends also on the form, size, and mass of the projectile.

If we consider the action of gravity alone, the problem is a very simple one. Since the force of gravity is always vertical, there can be no change in the value of the horizontal component of the velocity. The projectile, projected from any point O (see fig. 1) at any inclination, will some time or other reach the highest point A. At this point the vertical velocity will be zero; and, if the horizontal velocity were here suddenly reversed, the projectile would travel back along the same trajectory to O. As it is, the projectile proceeds along the path AO′, which must be exactly similar to AO. In short, the trajectory is symmetrical about the vertical line drawn through the highest point A. Reckoning from A, let us suppose the projectile to reach P′ after t seconds. Then, if the horizontal velocity is v, the distance of P′ from the vertical line AB—P′M namely—is measured by the product vt. But the projectile in falling through the height AM has acquired a vertical velocity gt, where g is the acceleration due to gravity. Thus the space fallen through, being measured by the product of the average speed and the time, is

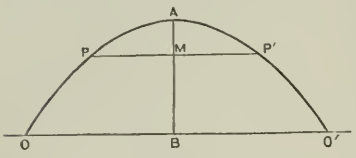

Fig. 1.

$$AM = \tfrac{1}{2}gt^2 = \tfrac{1}{2}g.MP'^2/v^2 = \tfrac{1}{2}g.MP^2/v^2.$$

The trajectory is therefore a Parabola (q.v.) with its axis vertical.

If we suppose the projectile to be projected with a velocity whose vertical and horizontal components are respectively u and v, then the angle of projection has its trigonometrical tangent equal to u/v. The time taken to reach the highest point is u/g; and the total range on the horizontal plane is

$$OO' = 2.OB = 2\,vu/g.$$

If we interchange v and u so that the tangent of the angle of projection becomes v/u, instead of u/v, we get still the same range. Generally, then, a given point, O′, can be reached by two trajectories with the same initial speed of projection. It is easy to show that the two corresponding directions of projection are equally inclined to the line that makes 45° with the horizontal; and the range is greater according as the components u and v of the given initial velocity are less unequal in magnitude. The greatest range is attained when $u = v = V/\sqrt{2}$, V being the total velocity of projection—i.e. when the angle of projection is 45°. In this case the range is V^2/g. Thus, to throw a ball to a distance of 100 yards or 300 feet it is necessary to project it with a velocity of at least 100 feet per second (nearly). Practically, however, because of the atmospheric resistance, it would need a distinctly greater speed of projection than that just given to attain the desired range.

A very simple observation suffices to show that the parabolic trajectory is only approximately realised in air. A well-driven cricket or golf ball will be seen to a spectator suitably placed to describe a trajectory which is distinctly asymmetrical about a vertical line through the highest point. The path will be found to be less curved during the ascent than during the descent; while the highest point is considerably nearer the end than the beginning of the trajectory. In fig. 2 the general character of a real trajectory, AB′, is compared

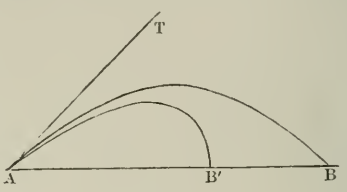

Fig. 2.

with the parabolic trajectory, AB, which would have been described if the air had offered no resistance. AT shows the direction of the initial projection. The same features causing deviation from the parabolic form are still more characteristic of the long flat trajectories of cannon-balls. These, projected with very high speeds, have their approximately horizontal velocities rapidly cut down in the earlier stages by the resistance of the air.

The first approximately accurate ideas of the resistance presented by the air to bodies moving through it at high speeds were obtained by Robins (see BALLISTIC PENDULUM). In our own times Bashforth, by means of his electric chronograph, has elaborately investigated the subject (see his *Motion of Projectiles* and *The Bashforth Chronograph*, 1890, the authoritative treatises on this branch of gunnery). Bashforth's results indicate that up to velocities of from 800 to 900 feet per second Newton's theoretic law that the resistance varies as the square of the speed holds practically true. The same law (but with a different coefficient) holds for all measured velocities above 1300 feet per second; but between the limits named the resistance depends on higher powers of the speed. Between the velocities of 1000 and 1100 feet per second—the velocity of sound in air, in fact—the resistance grows very rapidly, varying for a certain interval as the *sixth* power of the velocity. The resistance also depends on the form of the projectile, a spherical shot being nearly twice as much resisted as an ogival-headed shot of the same diameter and weight. For different sized projectiles of the same form the retardation due to the resistance is directly as the square of the diameter and inversely as the weight. It is usual to express the diameter in inches and the weight in pounds; and the following numbers are for an ogival-headed projectile, whose weight in pounds equals the square of its diameter in inches. The first line gives the velocity and the second the corresponding resistance-acceleration (negative):

Velocity.....	1500	1200	1100	1000	900	800	400
Acceleration	318	188	143	79	54	39	10

For a sphere of same weight and size, the resistance-acceleration for speeds lower than 850 feet per second is given by the formula $1{\cdot}183 \times 10^{-8}v^2$, where v is the velocity. From this it may be shown that such a sphere falling in air can never

attain a velocity of 522 feet per second. If projected downwards with a greater velocity it will be retarded, since the resistance due to the atmosphere is greater than the weight of the body. If projected upwards with a speed of 800 feet per second it will reach a height of only 5112 feet instead of nearly 10,000, and will return to earth again with a velocity of 351 feet. These results show why a meteoric stone never reaches the earth's surface with a velocity of more than a few hundred feet per second. It matters not with what relative speed the meteor may meet the earth. Once it gets into the atmosphere its kinetic energy is rapidly dissipated in heat, and much of its substance volatilised at the high temperature that results. Our atmosphere, in fact, acts as a practically perfect shield to meteoric bombardment.

For projectiles discharged from firearms, see the articles on Bullet, Cannon, Cartridge, Firearms, Gun, Rifle, Shell, Shot.

Projection is the representation on any surface of objects or figures as they appear to the eye of an observer. It thus includes Perspective (q.v.), and is most simply illustrated by the shadow of an object thrown by a candle on a wall; the shadow being the projection and the place of the light the position of the eye. The theory of projections is of great importance, both in mathematics and geography, being, in the former case, perfectly general in its application, while in the latter only the projection of the sphere is required. Projections of the sphere are of various kinds, depending upon the position and distance of the eye from the sphere, and the form of the surface on which the projection is thrown; thus we have the *orthographic, stereographic, globular, conical,* and *cylindrical or Mercator's* projections, all of which are treated of under the article Map. Another projection frequently employed is the *gnomonic.* In the gnomonic projection the eye is supposed to be situated at the centre of the sphere, and the surface on which the projection is thrown is a plane surface which touches the sphere at any one point (called the *principal point*). It is evident that a map constructed on the gnomonic projection is sensibly correct only for a circular area whose circumference is at a small angular distance from the principal point. From the position of the eye in the gnomonic projection (which is not suited for representing large portions of the earth's surface) it follows that all great circles or portions of great circles of the sphere are represented by straight lines, for their planes pass through the eye. The gnomonic projection derives its name from its connection with the mode of describing a gnomon or Dial (q.v.). The gnomic and stereographic projection of crystals is described and illustrated at Crystallography.

Prolapsus Ani is a common affection of the termination of the intestinal canal, and consists in an eversion of the lower portion of the rectum, and its protrusion through the anus. It may depend on a naturally relaxed condition of the parts, as in infancy, or may be caused by violent straining in cases of costiveness, piles, &c. Whenever it occurs the parts should be washed, and if possible replaced by careful pressure with the hand; and if they do not easily return the forefinger should be oiled and pushed up into the anus, and it will convey the protruded intestine with it, after which the patient should retain the recumbent position for some hours. If it cannot be returned by the above means surgical assistance should be at once sought. In order to remove the tendency to prolapsus the patient should regulate his bowels so as to avoid costiveness, should sponge the parts after every evacuation with cold water or soap and water, and if necessary use astringent injections, as, for example, a weak solution of sulphate of iron, 1 grain to the ounce. In young children the power of straining, and therefore the tendency to the occurrence of the protrusion, may be much diminished by preventing their feet from resting on the ground during defecation. Dr Druitt (in his *Surgeon's Vade Mecum*) recommends a plan first suggested by Dr M'Cormac—viz. that when the stools are passed the skin near the anus should be drawn to one side with the hand so as to tighten the orifice. If after the adoption of these means the bowel continues to descend certain surgical means must be resorted to, as destroying a portion of the relaxed mucous membrane by the application of nitrate of silver or nitric acid, or removing a part of the loose skin surrounding the orifice, with or without portions of the mucous membrane as well.

Prolapsus Uteri. See Womb.

Proletariate, a term used to denote the lowest and poorest classes of the community. It is derived, through the French, from the Latin *proletarii,* the name given in the census of Servius Tullius to the lowest of the centuries, who were so called to indicate that they were valuable to the state only as rearers of offspring (*proles*). The word has come much into use in the literature of Socialism (q.v.); see also Marx.

Prologue, a preface or introduction to a discourse or poem, as the *prologue* to Chaucer's *Canterbury Tales;* but more especially the discourse or poem spoken before a dramatic performance, corresponding to the Epilogue (q.v.) at its close. This usually stands outside the action of the piece, an external adjunct to it, being, indeed, a mere address to the public occasioned by the play. The introduction proper, again, belongs to the action itself, and this we find provided for in the prologue of Euripides, spoken by one of the characters, in narrative form, half within and half without the action; in the separate *induction* of many old English plays; and in the preludes and prologues of modern dramas like *Faust.*

Prometheus, a great culture-hero of Greek mythology, the son of the Titan Iapetus and of Clymene, brother of Atlas, Menœtius, and Epimetheus. Hesiod tells his history as follows: Once, under the reign of Zeus, when men and gods were disputing with one another at Mecone as to which portions of the victims at sacrifices were to be given to the gods, Prometheus, to outwit Zeus cut up an ox, and placed on one side the best parts covered with offal, on the other the bones covered with fat. Zeus was asked to choose, but, finding the deceit practised upon him, avenged himself on the mortals by withholding from them the fire necessary for the cooking of the meat; wherenpon Prometheus stole it in a hollow fennel-stalk, and brought it to them. Zeus next caused Hephæstus to mould a virgin of wondrous beauty, Pandora (q.v.), whom Epimetheus was unwise enough to receive as a present from Hermes, and thus brought through her all imaginable ills upon humanity. Prometheus himself was chained to a rock, and an eagle sent to tear his liver by day, while Zeus caused it to grow anew during the night. At length Hercules killed the eagle, and by the permission of Zeus delivered the suffering Prometheus. Thus far Hesiod's legend. In the splendid tragedy of Æschylus, the *Prometheus Vinctus,* Prometheus is an immortal god, a friend of the human race, who does not shrink from opposing the evil designs of Zeus against mankind, and even from sacrificing himself for their salvation. He is the long-suffering hero, who, although overcome by Zeus's superior might, yet does not

bend his mind. He takes from man the evil gift of foreseeing the future, but gives him the two infinitely superior gifts of hope and of fire; and he is the inventor of architecture, astronomy, writing, figures, medicine, navigation, the mystery of prophecy, the arts of metal-working, and all other arts which embellish and adorn life. For these boons conferred on the human race he is by Zeus's order chained to a rock in Scythia by Hephaestus, who fulfils this task reluctantly. Here he is visited by the Oceanides, by Io, and by Hermes, who endeavours to find out that which Prometheus alone knows, who will be the son of Zeus and his successor. Refusing to divulge this secret, he is struck by Zeus's lightning and hurled into Tartarus, whence he only re-issues after a time to undergo new sufferings. He is now fastened to Mount Caucasus, and the eagle, an offspring of Earth and Tartarus, comes to torment him daily. Cheiron the Centaur at last offers himself to supply the place of Prometheus in Hades—for on no other condition was he to be liberated than that some other immortal should offer himself in his stead. Cheiron, incurably wounded by Hercules, is accepted by Zeus. Other legends give a varying account, and make Prometheus the creator of man out of earth and water. Many have been the explanations of this myth, as that it represents the human mind in the consciousness of its own power, refusing to obey implicitly the will of Zeus. There can be no doubt that Prometheus is a culture-hero, analogous to the Maori *Maui*, and the Finnish *Wainamoinen*. The possession of fire to early man was a matter of enormous importance, and the legend of its being originally stolen from heaven by a primeval hero is very widely spread over the world. The Greek name means 'fore-sight;' Epimetheus ('after-thought') is obviously its opposite; and the beautifully ingenious identification of the solar mythologists with the Sanskrit *Pramantha*, the fire-stick of the Hindus, may be disregarded in the face of the existence of the myth far beyond the possible range of Aryan influence.

See the article FIRE, p. 630; E. B. Tylor's *Researches into the Early History of Mankind* (1865), and Kuhn, *Die Herabkunft des Feuers* (2d ed. 1886); older books on the myth by Weiske (1842) and Lasaulx (1843), and monographs by Holle (Berl. 1879) and Milchhöfer (Berl. 1882).

Promise. See CONTRACT, MARRIAGE.

Promissory-note, a written promise by one person (the maker) to pay another (the payee) or bearer a sum of money either on demand or on a future day. It is in the following form:

£100. LONDON, *1st January* 189–.

Three months after date I promise to pay to Mr William Smith or order One Hundred Pounds for value received. JOHN BROWN.

With certain necessary exceptions, such as the rules regarding acceptance, the law of Bills of Exchange (q.v.) applies equally to notes.

Promotion in the commissioned ranks of the British army, since the abolition of the purchase system in 1870, is obtained by seniority to fill a vacancy, by selection or by brevet for distinguished services. First appointments are as a rule obtained from the militia or through the Military Colleges (see MILITARY SCHOOLS). But three commissions, one in the Royal Artillery, one in the Royal Engineers, and one in the Cavalry, are given each year to cadets of the Royal Canadian Military College, and about ten second-lieutenants' commissions in the cavalry and line to sergeants who are specially recommended and hold first-class certificates of education. Besides these last all the officers of the Coast Brigade Royal Artillery (about 48), and of the Coast Battalion Royal Engineers (12), as well as all the quartermasters (about 315) and riding-masters (about 45) in the service, are commissioned as lieutenants from the ranks. Quartermasters and riding-masters receive honorary commissions, and are promoted honorary captains and majors for length of service or distinguished conduct in the field. Other officers are usually promoted, in their regiments, when senior of their rank, on a vacancy occurring, provided that they are well reported on and have passed the necessary examinations; but to equalise promotion a step is sometimes given out of the regiment. The highest rank of regimental officer is that of lieutenant-colonel. The succeeding steps of colonel, major-general, lieutenant-general, and general are given to officers specially selected to fill some appointment carrying those ranks. The seniors have the preference if otherwise eligible and not above the age limits, which are fifty-five, sixty-two, and sixty-seven years respectively. Field-marshals, not exceeding six, are specially selected from amongst the most distinguished generals. The *brevet rank* of major, lieutenant-colonel, or colonel may be given to any officer above the rank of lieutenant, and a lieutenant may be given a captaincy in another regiment for distinguished services. By this means a young and promising officer may be brought forward and placed in an important command. Thus, a major and brevet-colonel is eligible for promotion to major-general, thereby passing over many who are senior to him in length of service; but while serving with his regiment he does duty as a major only. Such an officer must, however, have been exceptionally fortunate to have obtained at least two brevets—viz. lieutenant-colonel and colonel, for only one step is given at a time. The rules governing promotion are constantly altered by royal warrant. The above rules were dated 1889. Non-commissioned officers are promoted by selection—the seniors, if otherwise qualified, having the preference—or for distinguished service. See also COMMISSIONS, RANK.

Promotion in the navy is governed partly by seniority and partly by selection. On a midshipman passing all his examinations for the rank of lieutenant, he receives his commission as sub-lieutenant, and is then advanced to lieutenant, except in a few special cases, by seniority. Those specially selected for promotion have either obtained a first-class in all subjects of examination, or else have distinguished themselves on active or other special service. Advancement from the lieutenants' to the commanders' list may be said to be by pure selection. As there are supposed to be 1000 lieutenants on the active list and only 250 commanders, it is inevitable that this should be the case. Except, however, for very distinguished service, lieutenants are not promoted before having served ten years in that rank, and the promotions are generally to be found among officers who have ten to fifteen years' seniority as lieutenants with a proportionate amount of good service. Promotion from the commanders' list to the captains' is also by selection; but there is this difference, that as the number of commanders is only some 70 in excess of the captains, any commander who puts in the requisite amount of sea-service can count, with a fair amount of certainty, on attaining his step. Captains and admirals are promoted on their respective lists by pure seniority; the three admirals of the fleet are selected for good service from admirals who have command of a squadron either as rear- or vice-admiral.

Promptorium Parvulorum was an English-Latin dictionary, compiled about 1440 by Geoffrey the grammarian, a friar-preacher at Lynn in Norfolk.

Prong-horn. See ANTELOPE.

Proof. See EVIDENCE; also ENGRAVING.

Proofs, Correction of. The corrections to be made on a 'proof' of printed matter are marked on the margin; and for this purpose an established set of signs or shorthand is used. The following specimen of a proof exhibits the application of most of these signs:

'To rule the nations with imperial swφy, to impose terms of peace, to spare the humbled, and to rcush the proud, resigning itto others to describe the courses of the heavens, and explain the rising stars; this, to use the words of the poet of the Æneid in the apostrophe of Anchises to Fabius in the Shades was regarded as the proper province of a Roman. The genius of the people was ~~even~~ more adverse to the cultivtion of the physical sciences than that the European Greeks and seen we have that the latter left experimental philosophy chiefly in the hands of the Asian and African colonists, The elegant literature and metaphysical specu$lations of Athens, her histories, dramas, epics, and orations, had a numerous host of admirers in Italy, but a *feeling* of indifference was displayed to the practical science of Alexandria. ['This repugnance of the Roman mind at home to mathematics and physics, extending from the Atlantic to the Indian Ocean, from Northern Britain to the cataracts of the Nile, annihilated in a measure ~~all~~ pure sciences in the conquered districts where they had ~~had~~ been pursued, and prohibited attention to them in the mother country.

Long, indeed, after the age of Ptolemy, the school in connection with which he flourished, remained in existence; &c.

(1) A wrong letter. After every mark of correction a line / should be drawn, to prevent its being confounded with any other in the same line. (2) A word or letter to be transposed. Where letters only are to be transposed, it is better to strike them out, and write them in their proper sequence in the margin, like a correction. (3) A *space* wanted. This mark is also used when the spacing is insufficient. (4) A space or quadrat *sticking up*. (5) Alteration of type. One line is drawn under the word for *italics*, two for SMALL CAPITALS, three for CAPITALS. (6) Correction or insertion of stops. (7) A word struck out, and afterwards approved of (Lat. *stet*, 'let it stand'). (8) A turned letter. (9) An omission. (10) A letter of a wrong fount. (11) A word or letter to be deleted. (12) Alteration of type. (13) A new paragraph. (14) Insertion of a clause. (15) A *space* to be removed or diminished. (16) A wrong word. (17) When letters or lines do not stand even. (18) Mark for a hyphen. (19) No new paragraph. (20) The manner in which the apostrophe, inverted commas, the star and other references, and superior or 'cock-up' letters and figures are marked.

The immediate object of a 'reader' or corrector of the press is to observe and mark every error and oversight of the compositor, with a view to make the printed sheet a perfect copy of the author's manuscript. This is on the supposition that the manuscript itself is quite correct, which is seldom the case; and therefore the duty of a good reader extends to seeing that there are no inconsistencies in orthography, punctuation, abbreviations, &c., and in many cases to the verification of quotations, dates, and proper names. Where extensive alterations, omissions, or additions are likely to be made by writer or editor, it is more convenient to take the proofs on long slips, before division into pages. The making of new paragraphs, or the suppression of those in type, should be avoided as causing trouble and expense.

The duty of securing consistency in spelling and punctuation is especially important in the case of works on which several writers are employed, such as newspapers and cyclopædias. The corrector has also to direct his attention to the numbering of the pages; to the arrangement of chapters, paragraphs, and notes; to running titles, &c. It is part of his business to observe the mechanical defects of the work—defective types, turned letters, inequalities of spacing between words, sentences, and lines, crooked lines, and to secure symmetry in verses, tables, mathematical operations, and such like. In almost all cases two proofs are taken, and in difficult works, such as those in foreign languages, tables, &c., even more. Lastly follows the revision, in which little more is done than seeing that the compositor has made all the corrections marked on the last proof. It is usual for the writer or author to reserve the correction of the second proof for himself.

The thankless and monotonous business of a corrector or reader is more difficult than the uninitiated would believe. It requires extensive and varied knowledge, accurate acquaintance with the art of typography, and, above all, a peculiar sharpness of eye, which, without losing the sense and connection of the whole, takes in at the same time each separate word and letter. See Book, Printing.

Propaganda (Lat. *De Propaganda Fide*), the name of a Congregation (q.v.), and also of a College, in Rome, the object of which is to direct and forward the propagation of the Catholic religion, especially among the heathen, although Christian dissenters from the Roman Church are also included in the sphere of its operations. The institution was originated by Pope Gregory XIII. (1572–84); but it was fully organised by Gregory XV., who in 1622 established a special Congregation for the purpose. This his successor, Urban VIII., extended and endowed, annexing a college for the education of missionaries to the several countries. One great feature of that college has been to provide for such work natives of the several countries, who are conveyed to Rome at an early age for the purpose of being specially educated in all the necessary learning of a missionary. This Congregation conducts the affairs not only of the missionary countries properly so called, but also of those in which the hierarchical organisation is not full and formal. The College of the Propaganda is a noble institution, with some 200 pupils of all countries, tongues, and complexions, who are not only maintained and educated gratuitously from a very early age, but are equipped and sent forward to their several destinations at the charge of the institution. It possesses a valuable library (30,000 vols.) and museum, and a polyglot printing-press. Its great festival is the Epiphany of our Lord—His 'manifestation to the Gentiles;' and this feast is celebrated by an exhibition of exceeding interest

and curiosity, at which are delivered recitations in every language represented in the College or its missions, amounting often to fifty or sixty. Of this festival Cardinal Mezzofanti (q.v.) used to be the guiding spirit.

Propertius, Sextus (for the second family-name, Aurelius, often given him there is no authority), the most impassioned of the Roman elegiac poets, was a younger contemporary of Tibullus, born about 48 B.C. in Umbria, probably at Asisium (the modern Assisi). Nearly all we know of him is gleaned from his writings, according to which he came of an undistinguished, comparatively poor family, lost his father in boyhood, and had a portion of his patrimony confiscated, after Philippi, by the Triumvirs, to reward their veterans, but retained means enough to proceed to Rome for education, and, having chosen his residence, like Virgil and Mæcenas, on the Esquiline, to make poetry the business of his life. The school then fashionable was the Alexandrian, represented by Callimachus and Philetas, and these he made his models, drawing from them his learned tone and his wealth of mythological colouring. In the political and martial movements of the time he took no part, though his patriotism was pure and strong—witness his exultation over the victory off Actium, his scorn of Cleopatra and her presumptuous ambition to dominate the mistress of the world, above all, his appeal to the Romans to renounce self-indulgence and to return to their neglected legends for the civic virtues and the heroism of 'the brave days of old.' Such was his precept; while his practice was the emotional poetic life, in the congenial society of Ovid, Virgil (whose *Æneid* he has nobly eulogised), the epic poet Ponticus, and Julius Bassus. Like them he won the favour of Mæcenas, to whom he dedicated a book of his poems, and even ingratiated himself with Augustus, whose achievements he duly celebrated. But the central figure of his inspiration was his mistress Cynthia, a lady somewhat older than he, whose real name was Hostia. For many years he cherished a glowing passion for this highly gifted and beautiful, but far from virtuous woman, till about 24 B.C. he disentangled himself from her spells. She died before him; but even after death she lived in his memory as she still lives in the poems that have immortalised her. Propertius left Rome, it would appear, only once, on a visit to Athens, when he may have experienced the shipwreck he has so vividly described. The year of his death has, with probability, been placed about 14 B.C. Of his poems only the first book, devoted entirely to Cynthia, was published during his lifetime; certainly the last of the four was given to the light, in terms of his will, by his friends. Its contents are youthful pieces, in which he celebrates the legends of early Rome in the style of Callimachus, and have a special interest in having most likely inspired Ovid to the composition of his *Fasti*—perhaps even of his *Heroides*. As a poet Propertius ranks high in Roman literature—the tone of the later criticism (with Goethe at its head) being one of increasing admiration for his native force, his eye for dramatic situation, his power over the reader's sympathies, giving the effect of reality to what in the hands of Tibullus or even Ovid is merely conventional. He has more in common with Catullus than with either of these, while he lacks the artistic graces peculiar to the three, being often rough to harshness and obscure from defect of finish.

For the English student there is an admirable text by Palmer (Dublin, 1880), and good critical notes by Paley and Postgate in their respective editions. There is no adequate translation of him in any language, Cranstoun's, in English (1875), being about the most faithful.

Property. See Heritable and Movable, Land Laws, Personalty, Possession, Real.

Propolis. See Bee, Vol. II. p. 21.

Proportion, in Arithmetic and Geometry, is a particular species of relation subsisting between groups of numbers or quantities. Notwithstanding that the idea of proportion is found to exist in perfection in the mind of every one, yet a good definition of it is a matter of extreme difficulty. The two definitions which, on the whole, are found to be least objectionable are that of Euclid and the ordinary arithmetical definition. The latter states proportion to be the 'equality of ratios,' and throws us back on the definition of the term *Ratio* (q.v.), which may most simply be considered as the relation of two numbers to each other, shown by a division of the one by the other. Thus, the ratio of 12 to 3, expressed by $\frac{12}{3}$, or 4, denotes that 12 contains 3 four times; and the ratio of 8 to 2 being also 4, we have from our definition a statement that the four numbers, 12, 3, 8, and 2, are in proportion, or, as it is commonly expressed, 12 bears to 3 the same ratio that 8 does to 2, or 12 : 3 : : 8 : 2. In the same way it is shown that 3 : 8 : : 13½ : 36; for $\frac{3}{8}$ expresses the ratio of the first to the second, and $\frac{13\frac{1}{2}}{36} = \frac{27}{72} = \frac{3}{8}$. It will be gathered from the two arithmetical proportions here given, and from any others that can be formed, that '*the product of the first and last terms* (the *extremes*) *is equal to the product of the second and third terms* (the *means*);' and upon this property of proportional numbers directly depends the arithmetical rule called 'proportion,' &c. The object of this rule is to find a fourth proportional to three given numbers—i.e. a number to which the third bears the same ratio that the first does to the second; and the number is at once found by multiplying together the second and third terms, and dividing the product by the first. Proportion is illustrated arithmetically by such problems as, 'If four yards cost six shillings, what will ten cost?' Here, 15 being the fourth proportional to 4, 6, and 10, fifteen shillings is the answer. The distinction of proportion into *direct* and *inverse* is not only quite unnecessary, but highly mischievous, as it tends to create the idea that it is possible for more than *one* kind of proportion to subsist. *Continued proportion* indicates a property of every three consecutive or equidistant terms in a 'Geometrical Progression' (q.v.)—for instance, in the series 2, 4, 8, 16, 32..., 2 : 4 : : 4 : 8, 4 : 8 : : 8 : 16, &c., or 2 : 8 : : 8 : 32, &c. In the above remarks all consideration of incommensurable quantities has been omitted. The definition given by Euclid is as follows: Four magnitudes are proportional when, any equimultiples whatever being taken of the first and third, and any whatever of the second and fourth, according as the multiple of the first is greater, equal to, or less than that of the second, the multiple of the third is also greater, equal to, or less than that of the fourth; i.e. A, B, C, D are proportionals when, if mA is greater than nB, mC is greater than nD; if mA is equal to nB, mC is equal to nD; if mA is less than nB, mC is less than nD; m and n being any multiples whatsoever. The apparent cumbrousness and circum-

location in this definition arise from Euclid's endeavour to include incommensurable quantities; throwing them out of account, it is sufficient to say that four magnitudes are proportional if, like multiples being taken of the first and third, and like of the second and fourth, when the multiple of the first is equal to the multiple of the second, the multiple of the third is equal to the multiple of the fourth. For example, take the numbers 12, 3, 8, and 2; multiply 12 and 3 respectively by such numbers as will give equal products, say by 4 and 16, the product being then 48 in both cases; the products of the remaining numbers, 8 and 2, by these multipliers are equal to one another, being both 32; and therefore these four numbers are proportional.

Prorogation, the continuance of parliament from one session to another. Prorogation not only suspends all business, but quashes all proceedings pending at the time, except impeachments by the Commons and writs of error and appeals before the House of Lords. A bill must be renewed after a prorogation as if it had never been introduced. See PARLIAMENT.

Prosecution. See CRIMINAL LAW.

Prosecutor, he who takes the initiative in bringing a person to trial on a criminal charge. In England a prosecutor may begin by taking steps to have the accused brought before a magistrate; the magistrate may send the accused for trial, or, in certain cases, he may bind the accuser over to prosecute. On a charge of perjury, conspiracy, libel, &c. the prosecutor must proceed before a magistrate, unless a judge or law officer of the crown has given him leave to prefer an indictment. In other cases, a prosecutor may, at his own discretion, begin by preferring an indictment which will come in due course before the Grand Jury (see JURY) at assizes or quarter sessions. The liberty of prosecution thus permitted is a valuable safeguard; the government cannot shield offenders by refusing to prosecute; it must, however, be remembered that the Attorney-general can always stop the trial of a prisoner by entering a *nolle prosequi*. In cases which concern the state it is the duty of the Attorney-general to prefer an indictment or information; in other cases the law was formerly content to leave the parties injured by a crime to commence proceedings at their own expense and risk. Of late years the government has shown a disposition to take upon itself the duty of prosecuting in cases where the public interest is concerned. In 1879 a public prosecutor was appointed; in 1883 the duties of this office were transferred to the solicitor to the treasury; and prosecutions are now usually undertaken by the Treasury or by local authorities. Criminal courts have also been empowered to allow costs to prosecutors; and these costs are now paid by the Treasury. In Scotland the procurator-fiscal makes inquiry in regard to crimes committed within his district; cases are prepared and conducted by the Lord Advocate or by one of his deputies; and prosecutions by private persons are practically unknown. In Ireland prosecutions are usually undertaken by crown solicitors and by counsel acting under the control of the Attorney-general. There are public prosecutors in the United States. See CRIMINAL LAW.

Proselytes (Gr. *pros-elytos*, Heb. *gerim*) was an English form of the Greek translation of the name given by the Jews to those heathens who became converts to Judaism. There were two kinds of proselytes distinguished: 'Proselytes of the Gate,'—i.e. heathen strangers, who, in order to be allowed to reside in Palestine, had undertaken to submit to the 'Seven Commandments of the Sons of Noah,' that prohibit blasphemy, idolatry, murder, incest, theft, disobedience to the authorities, and the eating of flesh with the blood in it: commandments which probably had grown out of certain restrictions originally put upon the 'strangers' by the Mosaic Law (Exodus, xii. 19; xx. 10, &c.). These 'Proselytes of the Gate,' or 'Sojourners,' could not claim all the privileges of an Israelite, could not redeem their first-born, and, at a later period, were not allowed to live in Jerusalem. The second class of proselytes was formed by the *gere hatsedek* ('Pious Proselytes'), or *gere haberith* ('Proselytes of the Covenant'). These accepted all the dogmas and customs of Judaism to their fullest extent, and were called 'Complete Israelites.'

Proserpine (in Latin Proserpina, a form of the Greek Persephone), daughter of Zeus and Demeter (Ceres). The story of her abduction by Pluto, god of the under-world, of her mother's unceasing search for her, and of her living part of the year above and part underground, is detailed under DEMETER. There can be little doubt that the myth is an expression of the revival of nature in spring after the death of winter. Proserpine was usually worshipped under the name of *Korē* ('maiden') along with her mother Demeter. The chief seats of her worship were Sicily and Magna Græcia; but she had also temples at Corinth, Megara, Thebes, and Sparta. The pomegranate is her symbol, and the pigeon and cock are sacred to her. In works of art she bears a cornucopia, or is represented with ears of corn and a cock.

See the works by Preller (1837), Förster (1874), and Overbeck in *Gricchische Kunstmythologie*, 4th book (1878).

Prosody (Gr. *prosōdia*), that part of grammar which treats of the rules of rhythm in metrical composition. See METRE, RHYME, BLANK VERSE.

Prosper of Aquitaine, the zealous champion of Augustine and Augustinian doctrine against the Semi-Pelagians, was born in Aquitaine about the end of the 4th century, was a prominent theologian in southern Gaul in 428–434, and in the latter year settled in Rome. The date of his death is not known. Besides letters, *Responsiones*, and pamphlets on the doctrines of grace and free-will, he wrote a chronicle, coming down to 455 A.D., a long hexameter poem against the Pelagians, and a *Liber Sententiarum* compiled from Augustine's works. There is an edition of Prosper's works by Le Brun and Mangeant (Paris, 1711). He is sometimes called St Prosper, the 25th June being his day in the Catholic calendar.

Prossnitz, a town of Moravia, 13 miles by rail SW. of Olmütz, has celebrated corn-markets and manufactories of clothing, linen and cotton stuffs, and distilleries and breweries. Pop. 18,417.

Prostate Gland, a firm body of muscular and glandular structure which surrounds the male urethra immediately below the neck of the bladder. In size and shape it is not unlike a chestnut. It occasionally is the seat of tumours, and of acute inflammation, sometimes leading to abscess; but far the most frequent disorder to which it is subject is a chronic enlargement occurring after middle life, which is the most common cause of retention of urine at that period. See URINE.

Prostitution dates unhappily from the earliest stages of human culture, and was a recognised institution in the times of the Jewish patriarchs (Gen. xxxviii. 15). The religious prostitution of women in honour of the goddess of fertility was usual in ancient Babylonia, and was an integral portion of the worship of Ashtoreth in Phœnicia; and similar licentious orgies disgraced the worship of the Egyptian Isis at Rome. Venal prostitution was legalised at Athens, and the Romans had regular

brothels. Christian kings issued at various times strenuous laws aiming at the suppression of the vice; some of the earliest examples of this legislation being found amongst the capitularies of Charlemagne. The Crusades gave a great impetus to unconcealed immorality; and in the middle ages it may be said that prostitution was recognised as a necessary and inevitable part of the social organism. In the Thirty Years' War swarms of women followed the armies of both sides. Modern states vary much in their attitude to this vice, either disregarding it, regulating it by specific ordinances, or trying to check it. In Japan (q.v., Vol. VI. p. 286) prostitution may even be regarded as an honourable self-devotion.

In the language of English law, a prostitute is a woman who carries on a course of habitual and promiscuous immorality. Acts of immorality are not always criminal; but in England a brothel or disorderly house is a nuisance, and a person who keeps such a house may be indicted and punished by fine and imprisonment; if two ratepayers make a complaint to the police the local authorities undertake the prosecution, and the expenses are paid out of the rates. The landlord of a house is also liable to penalties if it is used with his knowledge as a brothel. Special penalties are imposed on brothel-keepers harbouring thieves, and on publicans who permit prostitutes to assemble on their premises. The Criminal Law Amendment Act, 1885, deals with the offence of procuring any woman or girl to have unlawful connection with any person, or to become an inmate of a brothel at home or abroad, and with the offence of using threats, or false representations, or drugs for the same unlawful purpose. A search-warrant may be granted under the act in case there is reason to suspect that a woman or girl is detained as an inmate of a brothel. No punishment is inflicted on the men who frequent a brothel; not because the guilt of sexual vice is less in a man than in a woman, but because immoral women form a definite class of the community and immoral men do not. In the law of contract prostitution is regarded as a worthless or as an illegal consideration, according to circumstances. Thus, a bond providing for *future* illicit cohabitation is void, as being founded on an illegal consideration; a promise to pay money for *past* cohabitation is founded on no consideration at all, and is binding if made under seal. A person who lets lodgings or supplies dresses, &c. to a woman for the purpose of enabling her to live as a prostitute cannot recover the rent of the premises or the price of the goods sold. In some continental countries the law extends a certain toleration to brothels, and deals with prostitutes for the purpose of preventing the spread of venereal disease. By the Contagious Diseases Acts, 1864–68, a system of inspection was established in certain military and naval stations in England and Ireland; magistrates were empowered to order the examination and detention in hospital of women suffering from contagious diseases. As to the medical and moral results of the acts, there is an extraordinary conflict of evidence. A resolution condemning the whole system of examination was adopted by the House of Commons in 1883, on the motion of Mr Stansfeld; the acts have been repealed; and in India the same system was in 1897 abolished by the governor-general in council.

Protagoras, the earliest of the Greek sophists, was a native of Abdera, born about 490 B.C. Going to Athens about the middle of the century, he taught there and in other Greek cities, at home and in Sicily, a system of practical wisdom, specially fitted to train men for the duties of citizen in a Greek state, chiefly grammar, rhetoric, &c. The basis of his speculation is the proposition that 'man is the measure of all things,' a logical consequence of the teaching of Heraclitus. The *Theætetus* and *Protagoras* of Plato are devoted to a refutation of his doctrines. All Protagoras's works are lost. He himself perished at sea, probably between 421 and 415 B.C., whilst on his way to Sicily to escape a charge of atheism brought against him at Athens.

Proteaceæ, a natural order of evergreen exogenous plants, containing about 650 known species of shrubs and small trees, chiefly natives of South Africa and of Australia, and forming a remarkable feature of the vegetation of these regions. Some of them, as species of Protea and Banksia (q.v.), are frequently cultivated in gardens and greenhouses, being prized for their singular and elegant appearance, and their curious and often beautiful flowers. The timber of some of the larger species is used for various purposes; others supply much of the firewood of the Cape of Good Hope and Australia.

Protection, a theory of the proper attitude of government towards the industrial development of a nation. The protectionist believes that his government should aid in the development of the citizen and of the natural resources of the country. He also believes that this aid can often be given by the judicious stimulation of particular industries. Protection is not therefore, as is frequently asserted, a theory of foreign trade. It is true that the expression 'protective law' is sometimes confined to tariff or duty on imports which tends to increase the home production of a commodity while decreasing the amount imported. But, in the correct and broader view of the subject, all laws which tend to develop particular industries are protective.

Copyright 1891 in U.S. by J. B. Lippincott Company.

There are three ways in which a government can increase the amount of production in any industry. The first is by direct aid to those engaged in it. This may be accomplished through what is called in the United States an internal improvement—a term which may be applied to all works tending to increase the productive power of the country. It includes canals and railroads subsidised by government which open new fields to cultivation, dikes which keep back the water of a river, and reservoirs for the purpose of irrigation. Aid may also be extended to those engaged in an industry by a bounty or subsidy. It is true that the improvement by the government of the navigation of rivers or of harbours is often advocated by those who strenuously oppose bounties, and in fact all other forms of government aid to industry. And at first it would appear as if the payment of money in bounties simply stimulated the industry in which the payment was made, while any of the internal improvements above mentioned is an aid to all production. This is a fallacy. A canal between the Great Lakes in the United States, while it may be a considerable stimulus to the production of wheat and corn, because it brings

nearer to the principal markets sections suited to these cereals, has only the most remote effect on the production of cotton. On the other hand, the effect of a subsidy or bounty is never confined to the industry in which it is paid. It always has more or less influence on all auxiliary occupations. A bounty on raising hogs, as far as it stimulated their production, would increase the acreage devoted to corn. Thus we usually find that the consistent opponent of bounties, who, at the same time, advocates internal improvements, disapproves of the former on account of the moral effect of the direct payment of money by the government to the individual. Those who oppose such payments on strictly economic grounds are likewise usually found among the opponents of all internal improvements. Both internal improvements and bounties tend to increase production in some industries more than in others. In so far they are both protective.

The history of the public lands of the United States offers a striking example of protection through a direct reward held out by the government for prosecuting definite lines of industry. Public lands could be obtained by citizens on the easiest terms (see HOMESTEADS). A great stimulus was thus given to the production of those agricultural commodities for which the soil or situation of the public lands was suited. Most of the government land was capable of growing wheat, while comparatively little was adapted to cotton. In this way there was a distinct inducement held out to the citizen to grow wheat. This fact has had a profound effect on American agricultural industry.

The second method of protection, or the stimulation of an industry, is to impose burdens on other industries. This may be done by taxation or any restrictive regulation. The result of placing a burden on a particular industry is to lessen the amount of production in that industry, the energy thus suspended being turned into new channels; and the remaining industries of the country are stimulated in varying degrees. Thus taxes on alcoholic drinks, lessening the amount consumed, decrease their production, while increasing the production of many other articles. Such laws usually give a small quota of protection to many occupations, but at the same time there are cases in which the protective effect is confined to a single industry. When there are two commodities which can be applied to practically the same purposes, the taxation or absolute prohibition of one will not only greatly retard its consumption, but greatly increase the consumption of the other. This is particularly true where the difference between the two commodities, as in the case of beet and cane sugar, or of butter and oleomargarine, is more in the method of production than in the finished commodity. The laws fettering the sale and production of oleomargarine in the United States are as much a protection to the production of the cheaper and inferior grades of butter as the bounty on beet-sugar in Germany is to the production of the beet. Again, there are other commodities which, though they differ in kind, satisfy the same general purpose. In such cases the consumption of one can be retarded or prohibited in order to protect or stimulate the other. The taxation of wool, for instance, will lead to the greater consumption of cotton; this has been one of the marked results of the tariff on wool and woollens imported into the United States. In the same way, the taxation of one article of food will very frequently have the effect of increasing the consumption of another. This kind of protection has not found much expression in legislative intention, though, as in the case of the United States tariff on wool, it has frequently been one of the marked results of legislative action. In the middle ages export duties, or the absolute prohibition of the exportation of certain articles, was a popular method of stimulating the home production of particular commodities. Thus in England, during the reign of Edward III., the exportation of wool was prohibited, not to protect the wool-growers of the kingdom, but to bring about the establishment of woollen manufactories.

The third way in which it is possible to stimulate an industry is to burden the foreign producer of the commodity which it is desired to produce at home. The home producer is given a certain monopoly either by prohibiting the importation of the foreign commodity, or by exacting a tax for the permission to import. Nearly all countries in this manner protect some of their industries. So usual has it become to place an import duty on a commodity when a nation desires to foster its production within the bounds of the nation that the word 'tariff' is often used as if it were the only form of protection. For this reason we have entered rather more minutely than otherwise would have been necessary into the other methods of accomplishing the same object. They all increase the amount produced in some industries more than in others; they equally break the principles of *laissez faire*.

It is essential to keep in mind the theoretic similarity between a tariff law and a law providing for internal improvements. The economic principles which underlie a protective tariff are also the foundation of many other activities of the modern state, which all thinkers recognise as within the province of government, and the judicious exercise of which is universally conceded as absolutely essential to the welfare of the nation. The modern free-trader attempts to sever his theory of the necessary benefits to be derived from the freedom of international trade from that conception of the functions of the state which is usually called the doctrine of *laissez faire*. Yet to theoretically maintain his position on international trade it is necessary for him to establish a universal negative. He must show that any stimulation of an industry by government is always and necessarily bad. If government cannot aid particular industries by a tariff there is no reason why it should be permitted to do so in any other way. The argument for universal free trade is therefore not only fatal to protective tariffs, but to many internal improvements, as well as to many laws dealing with the public lands of a nation. Again, by realising the theoretic similarity of a tariff law and a law providing for an internal improvement, we shall avoid the mistake made by many that the indiscriminate stimulation of any industry that is not in a flourishing condition is the object of the protectionist. An internal improvement which cost more than the benefit it conferred would be an improvement only in name. It is only when such works increase the productive power of the nation that they are truly beneficial. In the same way, though a tariff or other protective law may stimulate many industries, it is only advisable if it increases the productive power of the people. The proof of protection as a theory lies in the demonstration of the possibility under given circumstances of increasing the productive power of a nation as a whole by the stimulation of a particular industry. The demonstration of the practicability of protection lies in the proof of the possibility of knowing, with reasonable certainty, when the circumstances are such as to render protection to an industry advisable.

In any investigation into the grounds on which protection is based we should distinguish between economic and political considerations. At different periods in the history of a nation there will be a great change in the relative importance of these

factors. Even among purely economic considerations the alteration of conditions causes a change in the emphasis which will be placed on different arguments. Nothing shows this more clearly than an historical review of the various considerations which have induced the people of the United States to adopt and maintain their high tariff policy. During the first fifty years of their history the American people seem to have been greatly influenced by the thought that it is more patriotic to buy home-made articles than to import from abroad. They felt that in case of war the nation should be independent. The commercial relations of the period were by no means as close as they are to-day. This fact justly gave to this argument a prominence which would be unwarranted at the present time. In the early history of the United States a great deal of stress was also very properly laid on the argument for protection to infant industries. The argument is based on the fact that to establish an industry is always a slow and expensive process. Even if it is shown that when the industry is once established its products would be raised or made at home cheaper than they can be imported, it may still be impossible to start the industry without aid from the government, or without such aid its establishment may long be delayed. If it is an agricultural industry, for instance, capital may have to be expended in preparing land for cultivation, or the people may have to learn through many failures how to raise the particular crop or care for the breed of stock. There never has been an agricultural product introduced into any country without four-fifths of the people who first undertook to produce it abandoning its cultivation as unprofitable, only to take it up again when those more persistent or with more capital have demonstrated its practicability. No clearer proof can be found of the difficulty of introducing an industry, which as it is now established is immensely profitable, than in the history of hog-raising in the western part of the United States. For years one who could raise hogs was looked upon as having a peculiar gift, simply because the majority who attempted to do so failed to make hog-raising pay. The protectionist considers that where a nation is reasonably certain that, when the industry is once fairly established, the people can obtain the product of that industry more cheaply than they now import it from abroad, but at the same time the expense of starting or developing the industry is considerable, then it is advisable for the government to aid in its establishment. The particular character of the aid given must depend upon circumstances. It may be that what is necessary to develop an industry is to open a certain section of country. Under these circumstances protection will be often wisely extended through internal improvements such as canals and railroads. On the other hand, if the people do not understand the method of production, a tariff on its importation from abroad would probably be the best method of protection. It would temporarily raise the price, and thus, holding out the hope of high profits, induce the people to make the necessary experiments in production.

Another purely economic argument for a protective tariff, which was also especially urged during the first decades of American history, is the advantage of a market for the surplus products of the soil within the boundaries of the nation rather than in a foreign country. The foreign nation is usually supplied with the same agricultural product from other nations, and very likely raises the commodity itself. The price of the exported commodity and the demand for it therefore depend on the climatic conditions of the previous year in distant countries, and is subject to great fluctuations. The violence of the fluctuations is increased by the fact that the foreign nation usually confines its demand to one or two products. The prosperity of a purely agricultural state becomes dependent, therefore, not only on the climatic conditions of distant countries, but on the condition of one or, at most, two crops. The difficulty, of course, is to determine when the extent of the fluctuation in prices renders a trade unprofitable which is otherwise advantageous. A general rule cannot be given. Each case must be examined by itself.

Closely allied to the last argument is one originally advanced by Mr Carey. He urged that a nation should maintain the proper balance of its industries. This does not mean that a people should produce things for which the soil or climate of their country is totally unfit, but rather that a nation should grow and manufacture within its boundaries all things which are suitable to the country, irrespective of the fact that they may be imported more cheaply than they can be produced at home. The proper balance of industry depends upon physical and social conditions. The cheapness of production is not the only test of the advantages to be derived from the extension of an industry. Mr Carey depended upon historical evidence to support these propositions.

All these arguments arose at a time when the country was comparatively new. They are especially applicable to immature conditions. To a young country the harmonious development of its natural resources and internal trade are much more important considerations than the ability to supply foreign markets. The foreign demand may be limited, or the changes in economic conditions witnessed in a new country rapidly growing may render it in a short time unable to compete with other nations in the production of those commodities in which it first excelled. The United States having passed beyond immature conditions, it is but natural that the arguments on which protection was advocated during the earlier stages of the nation's history should be replaced by considerations applicable to older nations.

The problems which surround the development and settling of land and the starting of manufactories mark the first period of a people's life in a new country. But as soon as large sections are thoroughly settled the problems which surround the distribution of wealth become prominent. The United States has proved no exception to this rule. In the period since the civil war the idea of protection to American labour has had great weight with the mass of voters. In many instances the labourers engaged in the protected industries are receiving higher wages than those engaged in similar occupations in Europe.

It is argued that wages would be reduced if the protective system was abandoned. At the same time it may be contended that, if the adoption of free trade by the United States would throw a large number of labourers in the protected industries out of employment, these would seek other industries, and by their competition force down all wages. This is essentially an argument from the standpoint of distribution. Arguments from production, however, are by no means wanting. In fact they are daily becoming more prominent, though owing to changed economic conditions they differ widely from those which were advanced when the country was in the first stages of its development. In the earlier decades of their history the American people protected those industries which, when once established, would soon compete with any other nation. Temporary protection was all that was contemplated. Its object was to turn the industries of the country easily and quickly into those channels in which they were ultimately destined to flow.

But experience has shown the Americans that if it is desirable to continue many of their present industries protection must be continued long after the name of an 'infant industry' has ceased to be applicable. The American protectionist, therefore, must refute the fundamental position of the modern free-trader—viz. that the cheapness of each particular commodity is always for the benefit of the whole people. For it follows from this proposition that protection can never be justified which does not, within reasonable time, reduce the cost of the commodity protected, rendering the protection itself no longer necessary. The latest arguments of the protectionist have consequently been directed towards the disproof of this proposition. It is contended that there are definite classes of circumstances in which the stimulation of particular industries, even at the expense of an increase in price of the protected commodity, will result in increasing the productive power of the nation—that is, the increased ability of the people of the nation to satisfy their desires. The laws of political economy naturally fall under two heads, subjective and objective, according as they are deduced from an investigation into the nature of man himself and his desires, or into the nature of the physical world. In looking at the physical world one notices that different countries are suited to the production of different commodities. To force peaches to grow in Canada and wheat in Cuba would be a waste of energy. At the same time it is not less true that in every part of the world the total results will be larger where there is a varied production than if the inhabitants confined themselves to raising a single crop. Another fact in the physical world which profoundly affects agriculture is what is called by economists the law of diminishing returns. It is based on the limited nature of the natural resources of a country, especially for the growth of particular commodities. If there is more than a certain quantity of wheat demanded, for instance, all the good wheat-lands being exhausted, poorer wheat-lands, requiring the expenditure of more energy per bushel, will be used to cultivate that cereal. The amount of energy which will be necessary to obtain a loaf of bread does not depend on the average energy required to produce a bushel of wheat, but on the energy which is needed to produce that portion of the wheat crop which is grown on those acres least suited for its cultivation. For as all the wheat is sold at practically the same price, that price must be high enough to compensate those who have expended the greatest amount of energy in producing it. It follows from these considerations that it is of prime importance to the country that every part of the land should be put as far as possible to its best use—that is, growing that for which it is adapted. If any land is required to grow a commodity for which it is ill suited the amount of energy which the people have to expend in order to obtain that commodity is greatly increased. If a man is left to himself he will not always use the land in the best way. By the best use is not meant that use which enables the producer to obtain directly from the land what will be for him the greatest amount of food. It is rather that use which, taking into consideration the wants and products of the rest of the world, tends to make the inhabitants of the nation obtain directly or through exchange the greatest amount of production. The protectionist contends that the peculiar economic condition of the United States, for instance, would make the adoption of free trade result in a bad use of the natural agricultural resources of the country.

Thus of all the products of the United States wheat and cotton are alone those which Europe especially demands. In cotton the United States has practically a monopoly, and its exportation is not affected by the tariff. The cultivation of wheat, however, would be greatly increased by any step in the direction of free trade. Suppose the Americans removed the duty on iron, England would send to the United States more iron than she does at present, and would buy more wheat to pay for the iron. As a result of free iron, wheat would be grown even more than at present on lands unsuited for its cultivation. It would require more energy to obtain a loaf of bread, as what has to be given in exchange for a product must compensate for the energy expended on what is produced under the most disadvantageous circumstances. The amount, therefore, which the inhabitants of the country, in which term we include the farmers themselves, would have to give for wheat would be increased. At the same time it is acknowledged that with the removal of the tariff on iron the amount of energy required to obtain a definite quantity of iron would be decreased. The protectionist argues that the people, by seeking to increase their foreign trade at the expense of home industries, would lose as consumers more than they would gain. It will be seen that the solution of the question depends upon two factors. In the first place it depends upon the proportion which wheat bears to iron in the expenses of the average man. If, on the repeal of the tariff, iron falls 25 per cent., and wheat rises 5 per cent., but the average man spends fifteen times as much in wheat as in iron, free trade in iron has caused actual loss in production. The people find more difficulty in satisfying their desires. Secondly, the solution depends upon the physical conditions of the country in respect to its capacity for wheat-raising—how far an increased demand for wheat will cause lands less suited for wheat to be planted with that cereal. From the above it will be seen that advantages of protection depend upon the particular circumstances of each case.

There is another argument which likewise attacks the major premise of the free-trader, and on which the Americans are beginning to lay some stress. This owes its origin to the fact that the desires of the Americans are at present adapted to European conditions rather than to those of their own continent. The protectionist believes that government can aid in the unconscious adaptation of the individual citizen to his environment. This can be done by the second method of protection instanced in the first part of this article; that is to say, the imposition of burdens on the commodities which satisfy the same desires as the commodity one desires to protect. To illustrate this from the use of cotton and wool in clothing. The climate of England is much damper than that of the United States. Wet cotton fibre is a better conductor of heat than wet woollen fibre. It is absolutely essential that the Englishman should have in his clothing a large proportion of wool. At the same time, cotton being more easily obtained than wool, it is a waste of energy to use the latter where the former can be employed without danger to health. The dry climate of the greater part of the United States renders it possible for the people to employ with safety a larger proportion of cotton in their clothing than is advisable in England. But the Americans, instead of taking advantage of their environment, tend to copy the fashions of London. Thus the tariff on wool and woollens, besides being defended on the ground of the protection it affords the sheep raisers, is also advocated on the ground that it unconsciously causes the people to use a larger proportion of cotton.

This review of the last two arguments by which

the protectionists in the United States have supported their policy shows something beside the fact that a change in economic conditions will produce a corresponding change in the influence of different arguments. It also shows that it is easy to imagine conditions, which at the same time are not unlikely to occur, in which the adoption of a protective policy, either through a tariff legislation, internal improvements, or bounties, will increase the productive power of the nation. The universal negative which asserts that under no circumstances can the interference with free competition increase productive power is disproved. Thus much has already been admitted by free-traders. But they contend that it is impossible for any one to tell exactly when a combination of circumstances exists which would render the protection of a particular industry advisable, and therefore it is better not to interfere with international competition. The argument admits that we can easily imagine whole classes of cases in which interference with free international competition in particular commodities would be highly beneficial, but objection is made to any action being taken, because we cannot tell exactly when it would be right to interfere. As a matter of fact, this argument is not aimed at protection, but against all changes in existing laws. If for a long series of years the policy of a nation has been to protect the iron industry, then according to this objection it has no right to adopt free trade in iron, because, while some may consider it desirable, that fact depends on circumstances which we can never exactly estimate or with absolute certainty determine. There is no intrinsic difference between the legislation for the purpose of increasing the productive power of the nation and developing its resources through a tariff and through an internal improvement. The action of men and of nations is based on probabilities. The best we can do at any time is that which we believe is most probably right. It is undeniable that it is more difficult to impose a proper tariff than to decide where a canal should be built. It may also be admitted that in some cases it is much more difficult to determine when protection is desirable than in others. Each case must be examined by itself. Any one who advocates a change in existing laws should have ground for believing that the change would be beneficial; but, believing that a change would be advantageous, he need not wait until he has arrived at absolute certainty before attempting to effect that change.

We have not attempted to answer many arguments of the free-trader. For the most part these arguments either go to show what the protectionist admits or disproves follies for which he never contends. One illustration of this last tendency will suffice. It is stated by the free-trader that protectionists desire a tariff or other protective law, because they think it will increase the amount of gold and silver coinage in the country. That there are many who do not realise that the value of the exports and imports always tend to balance each other must be allowed; but that many who are influenced by reason are protectionists because they think protection adds to the stock of the nation's gold and silver we cannot believe. The attempt to impose this argument on those who advocate a tariff is similar to that which would class the modern believer of a governmental policy which seeks to develop the natural resources of the country with the advocate of the mercantile system of the middle ages and its obsolete theory of the 'Balance of Trade.' This last was the belief that the only trade which is beneficial is that which at the end of a series of transactions showed a balance in money due by the foreign to the home country. There is probably nothing in the science of economics more definitely settled than that the apparent balance of trade is no indication of its profitableness to the nation.

The thought which truly underlies all protectionist arguments is that the government of the nation, being the chief among its social organisations, should not simply be the enforcer of civil order, but that it can and should aid in the advancement of the people and in the increase of their productive power. It is impossible, even if it were desirable, to increase simultaneously all the industries of the nation. Government aid to industry, if it comes at all, must come through protection to particular industries or classes of industries. The internal improvement as well as the tariff gives a greater stimulus to one occupation than to another. The advisability of such stimulation or protection does not depend upon the fact that it increases production along certain lines, but that it enables the people to satisfy their desires more easily. The protectionist does not claim that protection is always good, or that we can tell the precise moment when an internal improvement or a tariff becomes advisable, but he does claim that under certain circumstances great good can come to a nation from judicious aid to industry; and that, though we can never tell exactly when these circumstances exist, we can sometimes be as certain as of anything else in the domain of political science.

It is proper that mention should here be made of a theory which is popularly supposed to stand midway between free trade and protection—that of the fair-trader. Speaking broadly, it may be said that a believer in the fair-trade theory advocates freely opening the ports of his nation only to those countries which on their part admit, without restriction or tax, the products of his country. There are two senses in which this general attitude may be regarded. The first is essentially non-economic. It is an outcome of a sentiment for equality and equity, or an undefined feeling that a nation is conferring a benefit on another country when she admits the products of that country free of duty, and therefore she should not do so unless a corresponding advantage is given to her by the foreign nation. Nations, however, do not open or close their ports to foreign trade for the good of foreigners, but for their own advantage. A foreign government may exact a duty on our products when imported into their country, but this is no reason why we should or should not tax their products. On the other hand, if we regard the attitude of the fair-trader as denoting a belief that his government in treating with other governments should attempt to establish those commercial relations which are most advantageous to his country, his position is essentially that of a protectionist. It may often be advisable that a nation, for the sake of gaining an advantage in one direction, should forego an advantage in another. When this principle is applied to foreign relations it finds its practical expression in what are known as 'reciprocity treaties.' It is this policy which the protectionists in the United States are at present logically assuming in negotiating their commercial treaties with foreign nations.

See Henry Carey's works; *History of American Protective System*, by A. W. Young (1866); *Protection, a Boon to Consumers* (1867), and *The Protective Question Abroad* (1870), by J. L. Harges; *Plea for Limited Protection*, by Lord Bateman (1877; Amer. ed. 1878); *An Argument for a Protective Tariff*, by J. B. Wise (1880); *Government Revenue*, by Ellis H. Roberts (1884); *Protection to Home Industry*, by Robert Ellis Thompson (1886); *The American Protectionist's Manual*, by G. B. Stebbins (1888); *The Economic Basis of Protection*, by

Simon N. Patten (1890); *Our Sheep and the Tariff*, by the present writer (1891); Geo. B. Curtiss, *Protection and Prosperity* (1896).

[With the above article, by an American protectionist, Mr W. Draper Lewis, should be compared the article FREE TRADE, in Vol. IV., by Professor Shield Nicholson, written from the opposite point of view.]

Protective Legislation, a term applicable to legislation in promotion of Protection as opposed to Free Trade, is more specially used of legislation in favour of classes of the community thought specially to stand in need of it, the Factory Acts (q.v.) being a notable example. To the same category belong the Employer's Liability Act (see LIABILITY), the Merchant Shipping Acts, much of the legislation in regard to mines, Crofters (q.v.), and Irish tenants (see LAND LAWS). The supporters of the Laissez-faire (q.v.) theory of government, even when admitting justification for some of those measures, protest against others of them or parts of them as interfering with industry and commerce, and tending to limit freedom and establish a socialistic state-despotism. The proposal to limit the working day to eight hours is resisted on the same ground; and some extend their protest to free education, free libraries, and government measures for the housing of the poor. See *A Plea for Liberty*, edited by Thomas Mackay, with preface by Herbert Spencer (1891).

Protector, a title which has sometimes been conferred in England on the regent or governor of the kingdom during the sovereign's minority. It was given to Humphrey, Duke of Gloucester, in 1422, in the minority of Henry VI. Richard, Duke of Gloucester, was Protector in 1483, prior to his ascending the throne as Richard III. The Duke of Somerset, one of King Henry VIII.'s eighteen executors, was in 1547 constituted Protector during the minority of Edward VI., with the assistance of a council, consisting of the remaining seventeen executors; a dignity, however, which he enjoyed for but twenty months. Oliver Cromwell, in December 1653, took the title of Lord Protector of the Commonwealth of England, Scotland, and Ireland. In 1658 his son Richard succeeded to his title and authority, but was never formally installed in the Protectorate, which he resigned in the following year.

Proteids are an important class of substances, mostly of animal origin, but occurring also in the vegetable kingdom, of which egg albumen may be taken as a good example. The various members of the class are closely related to each other, and amongst them they make up the greater portion of the animal organism. The classification of the proteids is given in the article Animal Chemistry (q.v.). The most careful analyses of the various proteids show that they all closely approximate to the same ultimate composition, and contain about 53·5 per cent. of carbon, 7 of hydrogen, 15·5 of nitrogen, 22·5 of oxygen, and from ·9 to 1·6 of sulphur. The majority of the proteids exist in two modifications, the one soluble and the other insoluble in water. The latter modification can be obtained from the former by the addition of alcohol or ether, or of many mineral acids or metallic salts to their aqueous solutions. Coagulation also takes place in most cases by the application of heat, as in the case of egg albumen in boiling water. The proteids are all dissolved by strong solution of acetic acid, and by phosphoric acid. They are also dissolved by alkalies with formation of alkali sulphide. When heated with solution of mercuric nitrate containing a little nitrous acid, they assume a violet-red colour; and when the solution of a proteid substance in acetic acid is mixed with strong sulphuric acid, a violet-coloured solution is obtained, which in the spectrum shows characteristic absorption bands.

By the action of the gastric juice, of pepsin and dilute hydrochloric acid, and of several other ferments, the proteids are eventually converted into peptones. The latter are soluble in water, and are not coagulated by heating. See ALBUMEN, CASEIN, FIBRIN, and GLOBULINS.

Proteles. See AARD-WOLF.

Proterosaurus (Gr. *proteros*, 'first,' *sauros*, 'reptile'), a genus of fossil reptiles occurring in the Permian system, which is the lowest horizon at which reptilian remains have as yet been detected. It is of a primitive type, and belongs to a highly generalised group of reptiles. The skull is imperfectly known, but the teeth appear to have been anchylosed to the bone, and not implanted in distinct sockets, as was at one time supposed.

Protestantenverein, an association of Protestant ministers, professors, and others belonging to the 'liberal' or advanced school of theology in Germany, formed in 1863 to promote what its members insisted was the spirit of true Protestantism in opposition to what they regarded as reactionary and obscurantist. By the orthodox and conservatives the association was denounced as rationalist or infidel; and though since 1867 it has held annual meetings in various towns throughout Germany, and has several organs in the press of the Fatherland (including the *Protestantische Kirchenzeitung* and a *Jahrbuch*), it and its members have been treated with marked disfavour by the ecclesiastical authorities, membership in the association being, it is alleged, practically a bar to appointments or preferments. See Schenkel, *Der Deutsche Protestantenverein* (new ed. 1871).

Protestantism, a term derived from the part taken by the adherents of Luther in *protesting* against the decree passed by the Catholic states at the second diet of Spires or Speier in 1529. This decree had forbidden any further innovations in religion, and enjoined those states that had adopted the Reformation so far to retrace their steps as to reintroduce the Mass and order their ministers to avoid disputed questions, and to use and explain the Scriptures only as they had hitherto been used and explained in the church. The name is repudiated by a considerable section of the Anglican Church. See CHURCH HISTORY, LUTHER, REFORMATION.

Proteus, in the Homeric or oldest Greek mythology, appears as a prophetic 'old man of the sea' (*halios gerōn*), who tends the seal-flocks of Poseidōn (Neptune), and has the gift of endless transformation. His favourite residence, according to Homer, is the island of Pharos, off the mouth of the Nile; but according to Virgil, the island of Carpathos (now *Skarpanto*), between Crete and Rhodes. Here he rises at mid-day from the floods, and sleeps in the shadow of the rocky shores, surrounded by the monsters of the deep. This was the time when those who wished to make him prophesy must catch him. But it was no easy task. Proteus, unlike most vaticinal personages, was very unwilling to prophesy, and tried to escape by adopting all manner of shapes and disguises. When he found his endeavours hopeless he resumed his proper form, and then spoke out unerringly about the future.

Proteus, a genus of tailed amphibians with persistent gills, represented by two or three species in the caves of Carniola and Dalmatia. They are lank animals, towards a foot in length; and with their peculiar habitat may be associated the pale colour of the flesh, and the embryonic state of the eyes, which are hidden beneath the surface. It has been shown, however, that sensitiveness to

diffuse light persists. A nearly related genus, Necturus, lives in North American rivers and

Proteus anguinus.

lakes. The name *Proteus animalcule* was formerly used as a synonym for Amœba (q.v.).

Protevangelium, a very old apocryphal gospel attributed to James, the brother of the Lord (see APOCRYPHA); also used of a primitive gospel (Ger. *Ur-evangelium*), from which it has been held several of our gospels were derived. See GOSPEL.

Protococcus (Gr., 'first-grain'), a genus of very simple unicellular green plants, one species of which (*P. viridis*) is everywhere abundant as a green film on tree-trunks and damp walls, or in stagnant rain-water. The colour is sometimes reddish, and the organism may be found passively encysted during drought, and at other times actively motile with a couple of cilia. See ALGÆ.

Protocol (Gr. *prōtos*, 'first;' and *kolla*, 'glue'), (1) the rough draft of an instrument or transaction, and more particularly the original copy of a government despatch, treaty, or other document; (2) a record or register.

Protogene (Gr., 'first-born'), a granitic rock, composed of the same ingredients as true granite, but the mica is more or less altered so as to resemble talc, for which it was formerly mistaken. It received its name because it was supposed to have been the *first-formed* granite. It abounds in the Alps, and is found also in Cornwall. The clay produced by its decomposition is greatly valued for the manufacture of china. Protogene is now recognised to be simply an altered granite.

Proto'genes, a painter of ancient Greece, was born at Caunus in Caria, and practised his art at Rhodes, where he worked steadily on through the din of the siege of 305–304 B.C. A contemporary and friend of Apelles (q.v.), he was a slow and careful painter, sparing no pains to secure a natural and finished piece of workmanship. His best-known pictures were Ialysus (a Rhodian celebrity), a Satyr, 'Paralos and Ammonias' (sacred ships of the Athenians, executed for the Propylæa at Athens), 'The Thesmothetæ' (for the Athenian senate-house), 'Alexander and Pan,' 'Cydippe and Tleptolemus,' and some portraits.

Protonopsis. See MENOPOME.

Proto-notary, a member of the College of Proto-notaries Apostolic in the papal curia, whose duties are to register pontifical acts, make and keep the records of beatifications, &c.

Protophytes (Gr. *Protophyta*, 'first plants'), a term often applied to the simplest plants, such as Protococcus in the algoid, and Bacteria in the fungoid series. See ALGÆ, BACTERIA.

Protoplasm (*protos*, 'first,' *plasma*, 'formed substance') is a technical name for living matter. The term was first applied (1846) by the botanist Hugo von Mohl to the 'slimy, granular, semi-fluid' contents of vegetable cells, but before that Rösel von Rosenhof (1755) had studied the amœba, which is a unit-mass of relatively pure living matter, Robert Brown and other botanists had watched the rotation of the living substance inside the cells of some plants, and Dujardin (1835) had described the 'sarcode' of Foraminifera as 'a glutinous, transparent, living jelly.' After Dujardin and Von Mohl had thus directed attention to 'sarcode' and 'protoplasm,' observations on both gradually accumulated, the idea began to be mooted that the two substances were essentially the same, and in 1861 Max Schultze defined the cell as a nucleated mass of living matter or protoplasm. We cannot indeed say that the protoplasm is the same in the cells of plants and animals, for the precise nature of living matter defies our analysis; but we do know that 'the physical basis of life' has in all cases some common characteristics of structure and behaviour, diverse as are the ways in which its inherent activity may be manifested.

Protoplasm may be conveniently studied in the unicellular Protozoa—e.g. Amœbæ and Foraminifera; in the colourless cells of blood; in the ova of animals—e.g. of frog and pond-snail; in young vegetable shoots; or in the cells of a simple plant, like Chara or Spirogyra. When we submit the living matter in its natural state to microscopic examination we usually see a clear semi-fluid substance, sometimes obscured by granules, sometimes with numerous bubbles or vacuoles, sometimes with hints of a fine network traversing the whole. This vacuolated and reticular structure is much more easily demonstrated after the cells have been 'fixed' and stained, and, if necessary, 'sectioned' according to the practice of microscopic technique. In this state the network-like appearance of the cell-substance has been demonstrated in a great number of cases, and we may fairly regard it as characteristic (see CELL).

As the students of structure have been led with increasing carefulness of microscopic analysis to distinguish between the netted framework and a more fluid stuff in its meshes, so many physiologists distinguish the framework as the acting part, which lives and is relatively stable, from the content which is acted on, and is in a state of physical and chemical change. It is clearly necessary to discriminate between protoplasm in the strict sense and the substances with which the genuinely living matter is associated—food-stuffs about to be or being utilised, and waste-products which result from the vital activity. The food-granules and the waste-products we can analyse—they may be respectively glycogen and uric acid; the living matter we cannot analyse, for it dies at the moment our analysis begins.

All physiologists are agreed that waste-products are formed when work is done or while life lasts, and that living organisms have a characteristic power of repair. They are ever changing, and yet they remain more or less the same. Streams of matter and energy pass into the organism; they are somehow incorporated into the living capital, work is done and waste is given off, and the organism continues from day to day, or from year to year, relatively intact. For while 'the transfer of energy into any inanimate material system is attended by effects retardative to the transfer and conducive to dissipation,' the secret of protoplasm, as expressed by Joly in the language of physics, is that 'the transfer of energy into any animate material system is attended by effects conducive to the transfer and retardative of dissipation.'

So far we have stated facts; speculation begins when we try to express the precise relations of the

protoplasm to the waste and repair of the organism. Two somewhat different views must be considered. We may regard protoplasm as a complex substance or mixture of substances, which shares directly in the constant chemical and physical changes or metabolism of the organism. It is the climax of an ascending series of constructive or synthetic steps, by which food-material becomes more and more complex and unstable; it is subject as the organism lives to constant disruptive or analytic changes, which result in the liberation of energy and in the formation of simpler and simpler waste-products. Thus protoplasm is regarded as the changeful central substance in metabolism; it is continually being unmade, breaking up, and wasting as it lives; it is continually being made by the constructive processes of repair. We call the repairing or constructive process *anabolism*, and its chemically discernible steps *anastates;* we call the discharging or disruptive process *katabolism*, and its chemically discernible steps *katastates*.

But, on the other hand, we may regard protoplasm as a kind of ferment which influences the material round about it without itself being so directly affected as the previous conception implies. It is the relatively stable cause of metabolism, acting on less stable material of a less complex nature, acting upon it so that constructive anabolic processes or disruptive katabolic processes predominate for the time.

Furthermore, while all are agreed that in the life of organisms there is a characteristic alternation or antithesis between waste and repair, between discharge and restitution of energy, between katabolism and anabolism, there is difference of opinion as to the character of these antagonistic processes. The English physiologist Gaskell, prompted by his researches on the functions of nerves, some of which command activity while others induce rest, was led to regard what he called anabolism and katabolism as processes which bear to protoplasm a relation similar to that which sleep and wide-awake life bear to the organism. The 'winding-up' process of anabolism or restitution goes on (autonomically) of itself; the 'running-down' process of katabolism or discharge is determined by stimulus. Anabolism is comparable to the self-loading, katabolism to the stimulated firing of a gun. But the German physiologist Hering, prompted by his researches on colour-sensations, was led to regard what he called assimilation and dis-assimilation as two antagonistic kinds of activity, both dependent on stimuli which differ in their direction and results.

Apart from the precise biological problems which are raised when we seek to define the limits of our analytic knowledge of living matter, there is the great difficulty of forming any conception of the relation between life and its physical basis. We may cite Huxley's famous address on *The Physical Basis of Life* and Hutchison Stirling's essay *As Regards Protoplasm* as pre-eminent types of the numerous endeavours which have been made to secure accurate thinking about this supreme problem. Suffice it to say that in two ways we gain some knowledge of protoplasm or living matter. On the one hand, we know it as it is presented to our senses in living organisms, and the result of our analysis of this presentation leads us to recognise in protoplasm a marvellously subtle kind of matter and motion, or ultimately of motion. On the other hand, we have an intimate knowledge of protoplasm in our own brains, where its activity is manifested in thought. That we need not attempt to give an explanation of ultimate realities like protoplasm and thought, that thought is only a function of protoplasm, that protoplasm is only a form of thought, that thought and protoplasm are different aspects of one reality, are the respective conclusions of the agnostic, the materialist, the idealist, and the monist philosophers who have theorised about living matter.

See Biology, Cell, Physiology. The technical literature on protoplasm is not readily accessible, but references to researches since 1886 will be found in the annual *Zoological Record;* while some of the older investigations are cited by Prof. Geddes in the article 'Protoplasm,' *Ency. Brit.* The student will find the best introduction to modern speculations, such as those of Gaskell and Hering, in Prof. Michael Foster's article 'Physiology,' *Ency. Brit.*, in Prof. Burdon Sanderson's presidential address to the Biological Section of the British Association (Report Brit. Assoc. 1889), and *Nature*, xl. (September 1889).

Protop'terus. See Mud-fishes.

Prototheria. See Echidna, Mammals.

Protozoa (Gr. *prōton*, 'first,' and *zōon*, 'animal'), simple unicellular animals, contrasted with the multicellular Metazoa. Except in a few cases, each Protozoon is a single cell, a unit-mass of living matter physiologically complete in itself. Being such a unit involves being without organs and without sexual reproduction. Yet a Protozoon may have parts, and two individuals may unite in mutual fertilisation. A Protozoon is to any higher animal, from sponge onwards, as an egg-cell is to the body into which it develops. But the exceptional cases to which we referred are most important—they are loose colonies or aggregates of Protozoa. Formed by the incomplete separation of dividing units, they bridge the gulf between single-celled and many-celled animals. Simplest of Protozoa are such forms as Protomyxa, whose life is a succession of changeful phases, amœboid, encysted, flagellate. The others may be classified according to the predominance of one or other of these phases. The Rhizopoda, predominantly amœboid, include Amœba and others like it, Foraminifera, Heliozoa, and Radiolaria. The Gregarines are predominantly sluggish and encysted. The Infusorians are usually active, ciliated, or flagellate. These classes of Protozoa are discussed separately.

Prototracheata. See Peripatus.

Protractor, a mathematical instrument, used in drawing or plotting, for the laying down of angles. It is variously shaped, and may be circular, semicircular, or rectangular.

Proud-flesh is the popular term for coarse and too luxuriant granulations springing up on Wounds (q.v.) or Ulcers (q.v.). See also Inflammation.

Proudhon. Pierre Joseph, a noted French socialist, was born July 15, 1809, at Besançon, in which town his father was a poor cooper. Through the good offices of charitable friends, he received the rudiments of his education at the college of his native place, and from the first gave great promise of talent. While still very young, however, he quitted the institution in order to aid his family, who had fallen into great distress, and sought employment in a printing establishment. Here he was noted for the most punctual discharge of duty; and, in the hours not occupied in work, he contrived, by a rare exercise of resolution, to complete and extend his education. In 1830 he declined an offer of the editorship of a ministerial journal, preferring an honourable independence as a workman to the career of a writer pledged to the support of authority. In 1837 he became partner in the development of a new typographical process; was engaged on an edition of the Bible, to which he contributed notes on the principles of the Hebrew language; and in 1838 published an *Essai de Grammaire Générale*, in approval of which a triennial pension of 1500 francs was awarded to him by the Académie de Besançon. On this accession of funds

he paid a visit to Paris; and subsequently contributed to the *Encyclopédie Catholique* of M. Parent Desbarres the articles 'Apostasie,' 'Apocalypse,' and others. In 1840 he issued the work entitled *Qu'est-ce que la Propriété?* ('What is Property?') which afterwards became so famous. The nature of the doctrine announced in it is sufficiently indicated in its bold paradox, soon to be widely popularised—*La Propriété c'est le Vol* ('Property is Theft'). Notwithstanding his attack on property, which gave great offence to his patrons, Proudhon held his pension for the regular time. In 1842 he was tried for his revolutionary opinions, but was acquitted. In 1846 he published his greatest work, the *Système des Contradictions Économiques.* During the revolution of 1848 Proudhon attained to great notoriety. He was elected member of Assembly for the Seine department, but he could not there gain a hearing for his extreme and paradoxical opinions. He found more adequate scope for his energy in the press, publishing several newspapers, in which the most advanced theories were advocated in the most violent language. He attempted also to establish a bank which should pave the way for a socialist transformation, by granting gratuitous credit, but failed utterly. The violence of his utterances at last resulted in a sentence of three years' imprisonment, and in March 1849 he fled to Geneva, but returned to Paris in the following June, and surrendered at the prison of Sainte Pelagie.

While shut up there he married a young workingwoman. During his imprisonment he gave to the world the works entitled *Confessions d'un Révolutionnaire* (1849), *Actes de la Révolution* (1849), *Gratuité du Credit* (1850), and *La Révolution Sociale démontrée par le Coup d'État* (1852); the last of which is remarkable, in the light of subsequent events, for the clearness with which it states the alternative of *l'anarchie ou le Césarisme*, as pressed on Louis Napoleon, then president. In June 1852 he was set at liberty, but in 1858 was again condemned to three years' imprisonment, and retired to Belgium, where he continued to publish from time to time on his favourite subjects of speculation. Amnestied in 1860, he died in obscurity near Paris, January 19, 1865.

The theories of Proudhon cannot be presented in a clear or systematic form; we can only give some account of the most important of them. He held that property was theft, inasmuch as it appropriates the value produced by the labour of others in the form of rent, interest, or profit without rendering an equivalent. He maintained that one service can be duly repaid only by rendering another, whereas the owner of land and capital abuses his position by exacting all manner of service without giving an equivalent. His famous paradox respecting *anarchy*, which he regarded as the culmination of social progress, was simply an exaggerated and premature assertion of the great principle that the fully-developed man should be a law to himself—that is, the moral progress of man should make government and external law unnecessary. In the perfect society order would be secured and maintained in the absence of government through the reasonable self-control of the free individual. Laws, police, the whole machinery of government as now established are the marks of an imperfectly developed society. Personally Proudhon appears as an original and not unattractive character in the monograph of Sainte-Beuve, which unfortunately was not finished. His complete works fill 33 vols. (Paris, 1868–76); his correspondence, 14 vols. (1874).

See Sainte-Beuve, *Proudhon, sa Vie et Correspondance* (1872); A. Desjardins, *Pierre Joseph Proudhon* (1896); the articles ANARCHISM, SOCIALISM, and works there cited.

Prout, FATHER. See MAHONY.

Prout, SAMUEL, painter in water-colours, was born at Plymouth, 17th September 1783. He studied from nature, and sketched with Haydon through Devon and Cornwall, his drawings in the latter county being made for Britton's *Beauties of England and Wales.* In 1805 he removed to London, in 1815 was elected to the Water-colour Society, and in 1818 went to Rouen by Havre. The picturesque street-architecture and fine Gothic remains there made so strong an impression on his mind that afterwards his principal works were those in which architecture had a prominent place; and from time to time, in his after-career, he made excursions, ransacking every corner of France, Germany, the Netherlands, and Italy for picturesque architectural remains. Prout's name should be dear to all artists and amateurs, for there are few who have not been incited or instructed by his numerous elementary drawing-books, in the slightest of which talent and feeling for art are conspicuous. His water-colour drawings are characterised by decision in handling, great breadth, and clear and pleasing colouring. He died February 9, 1852.

See Ruskin's Memoir of Prout in *Art Journal* (1852); and his *Notes on the Loan Collection of Drawings by Prout and Wm. Hunt* (1879-80).

Provençal Language and Literature.

The Provençal language is one of the six principal branches of Latin speech, usually classified by philologists under the title Romance languages. The name Provençal, which appears to be derived from the *Provincia Romana* of Cæsar, was not used in the earlier middle ages except in the restricted sense of the language or dialect of Provence proper. The troubadours themselves used the term *lengua romana* (or *lo romans*). The term *langue d'oc* was also known in the middle ages, but was afterwards transferred to designate a province of France. The Provençal and other Neo-Latin idioms existed as dialects of the Latin previous to the Germanic invasions, having replaced the ancient languages of Gaul. Although the Provençal and the northern French had originally sprung from the same stock, they had gradually grown distinct from one another, until at the time of the troubadours they differed almost as widely as French and Italian. The Provençal language at the time of the troubadours extended far beyond the boundaries of Provence proper. It extended over the area from the Alps to the Pyrenees and the Mediterranean to the Loire. Beyond France it was known in the east of Spain—in Catalonia and Aragon, and in the Balearic Isles—also in Savoy, Piedmont, and part of Switzerland.

The pure Provençal idiom, in which the poets of the 12th century sang, was used by the higher classes over the whole of the district referred to, but the bulk of the people knew only their own dialects—viz. the Provençal (proper), Piedmontese, Gascon, and Catalan, all of which differed but slightly from one another. At the end of the 13th century, consequent upon the establishment of the French domination in the south and the introduction of the northern French language, the literary Provençal began rapidly to disappear, while the vulgar dialects still remained; and it was in them that the compositions of the later middle ages were written. The Provençal language was more highly inflected than any of the other Neo-Latin languages, and was the earliest of these to be fixed grammatically. It was highly adapted for lyric poetry, owing to its melodiousness and its rhyming facilities. The grammarian Vidal referring to it says: 'La parladura francesca val mais et es plus avineus a far romanz et pastnrellas, mas cella de Lemosin val mais per far vers et cansons et sirventes' (The

French speech is better and more suited for making epics and pastourelles, whilst that of Lemosin [i.e. the Provençal] is better for making love-songs and satires). In the modern Provençal dialects there is to be noted chiefly a greater simplicity of inflections and grammatical forms and a large admixture of French words.

The first employment of the Provençal language in writing dates back to about the 9th century. The few specimens that survive are mostly writings in Latin, but mixed more or less with Provençal words and phrases. It is to the priests and monks that are most probably due the earliest attempts at composition in the Provençal language. In order to arouse the religious sympathies of the people they composed or translated from the Latin into the vulgar idiom pious tales, allegories, legends of saints, &c. There were also introduced into the liturgy, along with the prayers and hymns in pure Latin, others in the popular dialect. In 813 at the councils of Arles, Mainz, and Tours preaching in the popular language was recommended to the clergy. Towards the close of the 11th century a revival took place in Provençal poetry consequent upon the religious wars of the Crusades and the introduction of the institution of chivalry. The influence of the Moors of Spain undoubtedly, too, had its effect in the development of Provençal poetry and culture. The poetry of mediæval Provence has much in common with that of the Moors.

Although it was in the north of France that epic poetry in the middle ages especially flourished, still in the south it was by no means so neglected as many have supposed. Among the earliest compositions in the Provençal language were undoubtedly epic romances, treating either of historical subjects, such as the struggles against the Franks or the wars with the Moors of Spain, or else of the semi-mythical deeds of Charlemagne and King Arthur which formed the basis of the Carlovingian and Arthurian (or Round-Table) legends. Of these old popular epics which were sung and so handed down from generation to generation we possess but few traces. From the middle of the 12th century epic poetry may be divided into popular and artistic. Of the first class but few specimens remain, but of the artistic epic they are more numerous, probably owing to the fact that, being recited and not sung, it was more necessary to commit them to writing.

The Provençals did not cultivate the drama like the French; in fact the only productions that might come under this head are pieces on pious subjects in dramatised form, such as the *Mystery of the Passion*, the *Marriage of the Virgin*, &c. Provençal literature was essentially poetic, and its prose works are of little importance. They were in the early period mostly translations from the Latin, sermons and chronicles—also the biographies of the principal troubadours. Later, in the 14th and 15th centuries, prose works became more numerous, and included scientific, juridical, philological, and other works. The lyric poetry is by far the best-known branch of Provençal literature. It was in lyric verse that the Provençal poets gave expression to the sentiments of chivalry and love—of that adoration and devotion to women which had become with them a sort of worship.

The word *troubadour* (in Provençal *trobaire*, *trobador*) is derived from the verb *trobar* (Fr. *trouver*, 'to find, invent, compose;' from Lat. *turbare*, 'to move,' meaning latterly 'to seek,' and also 'to find'). This verb was used only with reference to the composition of lyric poetry. Hence, strictly speaking, a troubadour means a poet of the lyric form. Epic poets were styled *noellaires* (Fr. *nouvellistes*, 'romancers'). The troubadours were of two classes—viz. professional and amateur. Amongst the latter were many nobles and even kings, as, for instance, Richard Cœur-de-Lion, Alfonso II. of Aragon, the Counts of Poitou, Provence, and Toulouse; of the professional troubadours also many were of high birth. Generally speaking, the latter were recruited from all ranks of society (merchants, soldiers, monks, lawyers, &c.), and they were of various grades. The majority of the troubadours led a wandering life, frequently travelling beyond the limits of their own country—more especially into Spain, visiting Catalonia and Aragon, and even Castile. Beyond the Alps they visited Piedmont, Lombardy, and Tuscany, where many of them settled. Others—mostly those who were tired of wandering—attached themselves to the households of the great feudal lords, wherein they played an important part. There were no fixed schools of poetry for learning the troubadour's art. They acquired it either by attaching themselves as pupils to some celebrated troubadour, or by visiting the great châteaux which the more distinguished poets were accustomed to frequent. The convent, too, was a great school of song; the monks had both the means and leisure to cultivate the taste for poetic composition, and there were many monks amongst the troubadours. At a later period professors of poetry established themselves in the chief towns of Provence; Peire Cardinal settled as such at Tarascon in the 13th century. The first of the troubadours of whom we know was Guillem IX., Count of Poitiers, a powerful noble of the south of France. He flourished towards the end of the 11th century. To the first half of the 12th century belong Cercamon (or *Cherchemonde*); Marcabrun, who was originally attached to the service of Cercamon in his wanderings; Peire d'Alvernh, a troubadour of great merit; and Bernart de Ventadorn, who was famed for the grace and sweetness of his poetry. The second half of the 12th and first half of the 13th centuries was the most brilliant period of Provençal poetry. Of the many poets who flourished during this period the following are the most distinguished: Gaucelm Faidit; Gui d'Uisel; Peirols; Arnaut de Maruelh, the author of many exquisite love-songs; the talented Folquet, Bishop of Marseilles; Peire Vidal of Toulouse, a versatile and most eccentric poet; Arnaut Daniel, the chief of the artificial school; Giraut de Bornelh, considered by the Provençals themselves to be the finest of all their poets (though Dante and Petrarch both regard Arnaut Daniel as superior to him); Raimbaut de Vaqueiras; Guillem de Cabestanh, a most melodious singer; the Monk of Montaudon, a powerful and unsparing satirist; Raimon de Miravals; Uc de Saint Circ; Guillem Adhemar; Bertrand de Born, the author of many warlike *sirventes;* Guillem Figueira; and Peire Cardinal, the great writer of moral and religious satire. The latter half of the 13th century shows the poetry of the troubadours in its decline, and few of the poets of this period deserve to be classed with those of the previous one. Towards the close of the century lived Guiraut Riquier, a poet of great renown, who has been termed the 'last of the troubadours.' He specially cultivated the popular forms of lyric poetry, particularly the *pastorcta*. Among the long list of troubadours (about 400 in all) there are only about a dozen women-singers of whom we know. Their works, so far as one can judge from the scanty fragments that remain, are much inferior in merit to those of the troubadours. The most distinguished among them was the Countess Beatrix de Dia, who has been termed the Sappho of Provence.

The compositions of the troubadours were intended to be sung to the accompaniment of some musical instrument. In most cases the poets themselves composed the melodies for their pieces. The text was called *motz*, the melody *son*. There is no doubt that many of the troubadours sang and accompanied their own compositions. But those who were unable to do so were obliged to have recourse to professional musicians to sing and play for them. These professional musicians they found among the *joglars* (Fr. *jongleurs*) or wandering minstrels. The origin of the *joglars* dates back to the time of the Romans; they were the descendants of the *joculatores*, who took part in the ancient circus-games. The *joglars* of the middle ages were a sort of travelling showmen, who gave performances at village feasts, and were often accompanied by trained dogs and monkeys. There were some of them, however, whose profession was rather more artistic than mere buffoonery or jugglery; they became the singers and accompanists of the troubadours. Some were in the service of the troubadours, and travelled about with them; others went about independently, singing the pieces they had either bought or had presented to them by the troubadours. The latter, as a class, held themselves much above the *joglars*, though it sometimes happened that *joglars* rose to the ranks of the troubadours.

It was only from the 12th century that a poetic system began to be fixed, and the different branches of lyric verse received distinctive titles. Previous to that period every lyric poem was termed *vers*, from the Latin *versus*, 'a hymn,' because the early lyric compositions were modelled on the ecclesiastical verses, whatever their subject might be. Epic compositions were termed *prosa*. The two principal branches of lyric poetry were the *canso* or love-song and the *sirventes* or satire. The *canso* was the outward expression of love and its various phases. In order to write the love-song (to *trobar*) it was essential, according to the ideas of Provençals, that the poet should be in love himself, that he should be inspired by the passion before he could give expression to it. Their idea of love, it may be remarked, was not wholly that of romantic adoration; hence the many licentious pieces among the lyrics of the troubadours. The *canso* generally closed with a few lines in which the poet apostrophised himself or his song, and commissioned it to explain his sentiments to his lady-love. This was termed the *tornada*. The term *sirventes* or *sirventesc* was used to comprise not only satirical poems, but generally every class of lyric composition that did not treat of love. These were divided into various classes—personal, social, political, moral, and religious—the last named including the songs of the Crusades. In their social satires the troubadours attacked with energy the vices and oppression of the nobles. Attacks, too, on the clergy were frequent, more especially at the time of the Albigenses war, when the poets sided (with one or two exceptions) with the heretics against the Church of Rome. In doing so they do not appear to have been influenced so much by questions of doctrine as by hostility to the northern French intruders, and we do not find any of them putting forward heretical opinions in their works, with the single exception of one piece by Peire Cardinal.

The crusades against the Saracens formed a constant theme enabling the troubadours to celebrate in song their love of daring and glory. Most of the crusade-songs we possess relate to the third crusade, which took place during the most flourishing period of Provençal poetry. In these songs they exhorted their countrymen to rise and take up arms against the infidels. War in general—not merely religious—was a favourite subject with the troubadours. The most famous writer of warlike *sirventes* was Bertrand de Born (q.v.), a typical mediæval baron.

The *tenso* was a sort of dispute or contention in verse in the form of a dialogue between two troubadours, generally upon some question relating to love or chivalry. Tensos actually did take place among the troubadours, although in many of their poems the antagonists would appear to be merely fictitious persons. This form of verse was of eastern origin, and was common among the Arabs and Persians.

Besides the *canso*, *sirventes*, and *tenso*, there existed also simpler, more popular forms of lyric verse. Originally the *balada* was a poem intended to be sung in dancing. It consisted generally of three strophes, and was remarkable for its graceful dance-like rhythm. The *pastorela* (*pastoreta*), or shepherd's song, was always a favourite form of verse with the Provençal poets. The *alba* (or dawn-song) and the *serena* (or even-song) were also cultivated by the Provençals. The latter is to be distinguished from the serenade, and was a poem depicting the longing of the poet for the approach of the night and the meeting with his beloved. *Novas*—tales in verse (compare the north French *Fabliaux*, q.v.)—were few and unimportant among the Provençals compared with those of the French.

The Provençal system of versification was most highly elaborated, the poets observing the most intricate metrical rules in their compositions. An instance of such elaborate verse is the *sestina*, which was invented by Arnaut Daniel and imitated by Dante, Petrarch, and other poets. The *sestina* was a species of verse consisting of six stanzas, each of six lines, in which the rhyming words of the first stanza were carried on through all the others in an inverted order. The opposite of the *sestina* was the *descort*, which was subject to no definite rules as regards either metre, rhyme, or length of stanzas. Some poets even purposely sought after discordance. A distinguished troubadour, Raimbaut of Vaqueiras (1180–1207), in one of his pieces uses five different languages (viz. Provençal, Tuscan, French, Gascon, and Catalan) in five succeeding verses, the sixth being a mixture of all five. The *sonnet* is frequently supposed to have been of Provençal origin. But the only two examples we know of in that language were by an Italian who composed in Provençal, Dante da Majano. The probability is that it was peculiar to the Italians, though doubtless it was the outcome of the influence of Provençal versification. *Sonet* in Provençal is simply identical with *son*, meaning melody.

The two distinguishing characteristics of Provençal versification are the rhyme and the syllabic accent. Some have supposed that in their predilection for rhyme they were influenced by the Moors, but it is more than likely it was natural to the Provençals. The great number of final syllables of the same sound existing in the declensions and conjugations of their language offered great ease of rhyming, and doubtless this had much to do with the formation of their poetry. Owing to their excessive regard for form, there is noticeable in the lyrics of the troubadours a certain sameness or want of variety of sentiment, and a tendency to be artificial rather than natural. Yet the high merit of their poetry must be acknowledged when we consider how rough were the times in which they lived, and how few literary models they had to guide them. The culture of the Greeks and Romans had long been extinct, and of classical literature they knew nothing, whilst at the time of the highest point of their development the poetry of northern France, of

England, of Germany, and of Italy was yet in its infancy.

Rapid as had been the rise of Provençal poetry, as rapid was its decline. What more than anything else was the cause of this decline was the war against the Albigenses (q.v.) in the 13th century, which proved disastrous to the nobles of the south of France. Their lands were laid waste, their castles destroyed. Besides this, with the establishment of the French domination in the south the French language began to be generally used among the upper classes; thus there was no longer any encouragement for the troubadours. Their poetry ceased to be cultivated as formerly. The clergy, too, in their fanatic endeavours to extinguish heresy, destroyed large numbers of Provençal works, and in a bull Pope Innocent IV. styles the Provençal a heretical language, and forbade the use of it to the clergy. With the 13th century the real literary life of the Provençals had disappeared. The two following centuries can only be regarded as an afterperiod in which the traditions of the troubadours still lingered on. In the first half of the 14th century an effort was made to revive the old poetry. Seven citizens of Toulouse, under the title *La sobregaya companhia dels set trobadors de Tolosa*, established in that city a society of song. Under the auspices of this society were organised *Jeux Floraux*, or poetic contests, at which prizes were given. The activity of the society was not confined to Toulouse; branch societies were formed throughout the south of France, and even in Catalonia and Aragon; but, though it existed for several centuries, this society could never effect what it aimed at—viz. the restoration of the brilliant period of Provençal song. In the 14th and 15th centuries prose works became more numerous. Such were learned treatises—theological, medical, legal, and philological—local chronicles, and pious tales or legends.

During the following three centuries there are almost no Provençal works worthy of notice. In the 19th century, however, a new poetic activity began to manifest itself, commencing with the poet Jacquot Jansemin, or Jasmin (q.v.), and after him Romanille, the founder of the Society of the Felibres (which has in view the preservation of the Provençal language and customs), Mistral (q.v.), a poet of great genius, Aubanel, and others. Poetic festivals, like the *Jeux Floraux*, have also been introduced to aid the movement.

On the subject of the Provençal Language see Diez, *Grammatik der Romanischen Sprachen* (1836–38; 5th ed. 1882); Raynouard, *Lexique Roman* (1838–44), and his *Grammaire comparée des Langues de l'Europe Latine* (1821); Mahn, *Grammatik u. Wörterbuch der Altprovenzalischen Sprache* (1885 *et seq.*); D. B. Kitchin, *An Introduction to the Study of Provençal* (1887). On the literature see Diez, *Die Poesie der Troubadours* (2d ed. 1883), and *Altromanische Sprachdenkmäler* (1846); Raynouard, *Choix de Poesies originales des Troubadours* (1816–21); Fauriel, *Histoire de la Littérature Provençale* (1846); Bartsch, *Grundriss zur Geschichte der Provenzalischen Literatur* (1872), and *Chrestomathie Provençale* (4th ed. 1880); Hueffer, *The Troubadours, a History of Provençal Life and Literature* (Lond. 1878); Mahn, *Die Biographien der Troubadours* (2d ed. 1878); Gatien-Arnoult, *Monuments de la Littérature Romaine depuis le 14me Siècle;* Milá y Fontanals, *Los Trovadores en España* (Barcelona, 1861); Paul Meyer, *Les derniers Troubadours de la Provence;* and Böhmer, *Die Provenzalische Poesie der Gegenwart* (1877).

Provence, formerly a maritime province of France, was bounded on the S. by the Mediterranean, and comprised the modern departments of Bouches du Rhône, Var, Basses-Alpes, and parts of Alpes Maritimes and Vaucluse. It included a portion of the Roman province of Gaul generally called simply *Provincia* ('the Province'), whence it derived its name. The Provençal (q.v.) tongue, however, was spoken over a much larger area (see also the section on the language and literature of FRANCE). Provence was overrun in the 5th century by the Visigoths and Burgundians, for a time was under the Saracens, and in 879 was mostly incorporated with Cisjuran Burgundy (q.v.) and with it was attached to Germany. The main part of the region remained, however, under the Counts of Arles, also known as Counts of Provence, and was practically independent. Early in the 12th century the countship passed by inheritance to Raymond Berengar, Count of Barcelona, and under the protection of his successors Provençal poetry attained its zenith. In 1245 the last count died, and the inheritance passed, through his daughter, to her husband Charles of Anjou, who united Provence with Naples. Under the Angevin princes the constitution of Provence, with its three estates holding the power of the purse, was well balanced and free; and it is possible that through Simon de Montfort (q.v.) the English parliamentary constitution may be indebted to it. The last of the counts, Charles, grandson of René the Good (q.v.), bequeathed his county to the dauphin of France; and it was united to that county in 1486 by Charles VIII.

Several of Daudet's works give vivid pictures of Provençal scenery, life, and character; and there are histories of Provence by Papon (1777–86) and Mercy (1830), and descriptive works by Garcin (1833) and Lentheric (1879). Descriptive sketches of some of the antiquities and architecture are given in Baring-Gould's *In Troubadour Land* (1891). See also ANJOU, FRANCE, AVIGNON.

Proverbs. All attempts to define a proverb, from the time of Aristotle downwards, have been unsuccessful. One of the difficulties is to find an essential difference that will not admit or exclude too much, and another is the diversity of opinion among parœmiographers as to where the line should be drawn. Some would include almost any form of popular phrase, while others, like Giusti, refuse to recognise anything that is not a sentence containing a precept or admonition of some sort. In default of an exact definition we must be content with descriptions, such as Earl Russell's—'The wisdom of many, and the wit of one,' or that of Cervantes—'Short sentences drawn from long experience,' or the more complete if less pithy one of Cipriano de Valera—'Short sayings, sententious and true, and long since accepted as such by common consent.' This last has the merit of recognising what is in truth the distinctive characteristic of the proverb, that it is a popular current saying adopted as a convenience by the community. All the qualities said to be essential to it, shortness, sense, salt, and the rest, are subsidiary to this. To be current it must be easily remembered, and therefore, within certain limits, short; without sense it would have no value, and without salt it would not take the popular fancy. But there is another quality no less essential than these which seems to be always ignored, and that is general applicability. Unless a saying is capable of being applied to a variety of cases it can never become a proverb. Lord Palmerston's famous dictum, 'Dirt is only matter in the wrong place,' has sense, salt, and shortness, but it will never be a proverb. It is of no use except in sanitary discussion and when dirt is in question. Lord Derby's answer, after trying a South African port specially recommended for gouty subjects, 'I prefer the gout,' has a much better chance, for it serves every purpose of 'The remedy is worse than the disease,' and is far richer in salt. A proverb is in fact a colloquial coin, not for exclusive dealing at any one particular stall in the market, but

negotiable at the butcher's as well as at the baker's; and it is in this its numismatic character that the essence of the proverb lies. A wise man's saying may be ever so wise, pithy, and pointed, but it is only *his* saying, and nobody is bound to take it as a settlement of any question. The proverb, on the other hand, has been adopted time out of mind and stamped by common consent as the recognised expression of public opinion. It has thus become by prescription a legal tender in controversy, while the other is only the cheque of a presumably solvent capitalist. In this respect proverbs and ballads are on precisely the same footing. They derive their authority from popular suffrage, and take their stand not as the issue of this or that man's brain, but as the adopted utterances of the people at large. But there is this difference between them, that the ballad had a maker, whoever he may have been, but no man ever yet made a proverb. He may have made the original saying, but the forces that made it a proverb were entirely beyond his control. No man by taking thought can add one proverb to his language any more than one cubit to his stature.

It would be a mistake, however, to fancy that every proverb must have had its germ in some wise or shrewd remark. Some are fables in little, or the concentrated essence of fables; and, as might be expected, a large number of the proverbs of the East, the birthplace of the fable, are of this sort. Every oriental collection abounds in proverbs like 'The ant got wings to her destruction,' 'They came to shoe the Pasha's horses, and the beetle held out his foot,' 'They asked the mule, "Who is thy father?" "The horse," said he, "is my maternal uncle."' By purists, perhaps, these and others of the same species, including the familiar 'Pot and Kettle,' may be denied a place among the proverbs proper; but they fulfil all the functions of the proverb, and they serve moreover to show how near akin are these two venerable vehicles of old-world wisdom, the fable and the proverb. Nor is the proverb of necessity the *wit* of one. Sometimes it is the simplicity or naïveté of one, and the wit lies in the application of it by the many. The Viennese have a good specimen of this kind. The late Emperor Ferdinand, driven for shelter one day into a peasant's house, took a fancy to some dumplings that had been just cooked for the family supper. The court-physician, being responsible for the imperial digestion, remonstrated, but his majesty's gracious answer was 'Kaiser bin i', knödel muss i' haben'—'Emperor I am, dumplings I'll have'—which became in course of time a recognised comment in cases of pertinacity. Here we have what is very rare, a proverb traced to a definite source; a few instances there are like 'A bridge of silver for a flying foe,' which was, it is said, a saying of the 'Great Captain,' Gonsalvo de Cordova; but as a rule the proverb is a scrap of unfathered wit or wisdom that came into the world nobody knows how. And here, too, we have a proof that though many regard the proverb as a mere fossil, there is still vitality in it. No doubt modern society has recourse to proverbs in conversation much more sparingly than was usual in the days of our forefathers, and the reasons are plain enough to see. To accept a proverb as an answer implies deference to authority and is in effect an acknowledgment of the wisdom of our ancestors. There is necessarily an antagonism between the proverb and individualism or self-assertion or self-conceit, or whatever other name we may choose to give it. The office of the proverb is to hit the nail on the head, to put the matter in a nut-shell, to bring back discussion to the point at issue, to check prolix argumentation. In all languages it condemns loquacity and commends silence. It is in fact a primitive form of 'closure.' If an Arab or Persian orator waxes fervid on the theme of equality and bombards his hearers with pompous platitudes about Nature's law, some graybeard will ask, 'Hath God made the five fingers of thy hand all equal?' and *solventur risu tabulæ*. In the nature of things, therefore, it is impossible that the proverb should be popular among the worshippers of excellent speech. The Celtic races, it may be observed, never greatly favoured proverbs. But for all that proverbs are very far from being the dry bones they are sometimes supposed to be. If any one took the trouble to register carefully all the proverbs or references to proverbs that came under his notice in the course of a day, making a note of allusions in his newspaper, whether in leaders, parliamentary, law or police reports, letters from correspondents, critiques, or puffing advertisements; jotting down those he overhears in the railway carriage or tramcar, those dropped in business conversation, in chat at the club, in table-talk at and after dinner; and in fact from breakfast to bedtime keeping his ears open for proverbs, he would find probably that they enter into our daily speech to a much greater extent than he had suspected. We are apt to use proverbs automatically. So completely have they engrafted themselves that we talk of gift horses, and half-loaves, and a bird in the hand, and sauce for the goose mechanically and without any thought of speaking proverbially. There is no family perhaps that has not proverbs or rudimentary proverbs of its own, founded on some adventure or drollery or blunder of one of its members, and used proverbially by all, often to the perplexity of the uninitiated visitor; and what is true of the family is true of the community on a more extensive scale. It has its own current sayings, allusions, comparisons, similitudes, incomprehensible to the outsider, but full of meaning to all who are to the manner born. Of these there will be now and then one more generally applicable and negotiable than the rest, with more of the true proverb metal and ring in it, which in time will pass the bounds of the community and become the property of the nation. A man sees another bolting out of his house, and asks what he has been about there. 'You 'll see when the eggs come to be fried,' says the other, making off; which is explained when it is time to fry the eggs and it is found out that the frying-pan has been stolen. It will be first a family joke; then a parish joke; then a stock saying in the market-place—'very good; time will tell; you 'll see when the eggs come to be fried;' then a saying in many market-places; and so at last a proverb. This is the actual story of one enshrined in Don Quixote—*Al freir de los huevos*.

As they pass from the family and the community to the nation, so they pass from one nation to another. The purely national proverbs form only a portion of the proverbs in any language. It almost seems as though there had been from time immemorial a kind of proverb exchange through which any serviceable proverb in one language passed into any other that stood in need of it; and this makes it a matter of difficulty, or rather impossibility, to settle the nationality of many of the best and most familiar. We are not, however, to jump at once to the conclusion that proverbs which are identical or nearly so must be in every instance merely versions or variants of one common original. To take an extreme case, our old friend the swallow that makes no summer is current now in sixty or seventy versions, and was current more than 2000 years ago, a date which allows ample time for it to have penetrated into the remotest corners of Europe. But it does not by any means follow that none of these came into existence independently. The

remark is one which must have been made at first hand in many a tongue on many a spring day. 'Summer!' cries the young man, 'Lo, a swallow!' 'Nay,' says the old one, with that repression of youthful optimism which is the privilege of age, '*One* swallow,' &c. But undoubtedly in most cases of widely distributed proverbs the probability is on the side of a common ancestor. It is not easy, for instance, to see how that one about the gift-horse's mouth, which was, as we know, 'a vulgar proverb' in the time of St Jerome, could ever have been independently produced. That two minds should hit upon precisely the same illustration for the same thought may be within the bounds of possibility, but that in each case a proverb should be the fruit of it pushes the coincidence to the utmost limits of chance.

It is obvious that the greater number of these proverbs which seem to be common property must be of eastern birth. If we find a proverb in English, German, Italian, and Spanish, and also in Arabic, Persian, and Hindustani, which is the more likely—that it has passed from Europe to Asia, or from Asia to Europe? A wide distribution argues antiquity, for necessarily the proverb travels slowly; and, go back as far as we may, we find the proverb, the fable, and the parable working together in the East. When David appealed to Saul it was with 'a proverb of the ancients,' and it was with proverbs that the prophets drove home their words, proverbs that are, many of them, in use there to this day, like 'As is the mother, so is her daughter,' and 'The fathers have eaten sour grapes, and the teeth of the children are set on edge.' The sayings of 'them of old time' cited in the Sermon on the Mount—'Judge not that ye be not judged,' 'The straw in another's eye thou seest, but not the beam in thine own,' and others, are still current in Syria. 'One sows and another reaps' and 'Who makes a trap for others falls into it himself' are Turkish, and 'Where the corpse is there the vultures will be' is a Bengali proverb. The proverbs that are strictly national have an interest of another kind. Coming directly from the people, the chosen vehicles of their sentiments and opinions, they naturally reflect the habits of thought, the turn of mind, the way of looking at things, that prevail among those who use them. Any one at all versed in comparative parœmiology will be able for the most part to make a shrewd guess at the original language from a translated specimen. They reflect other things too—often the history of the nation they come from. The Spaniard, as he was before Ferdinand and Ximenez bridled Aragon and Castile, makes himself heard in 'The king goes as far as he may, not as far as he would;' there are Teutonic proverbs older than Luther, in which his very spirit seems to speak; there are Italian proverbs that, in their cynicism, distrust of mankind, and open advocacy of lying, are more eloquent on the state of society in mediæval Italy than any of her historians. And the differences they suggest are often curious. The devil figures prominently in the proverbs of Europe; but in those of the Latin races he is always treated with respect, or at any rate credited with astuteness, the only exception, perhaps, being the Italian one that accuses him of weaving a coarse web. In Teutonic proverbs, on the other hand, he is held up to ridicule on the score of his amazing simplicity. He tries to get wool off his pigs; he takes a donkey for a cow, and remarks how soft its horn is; he sits down on a swarm of bees, because where there is singing going on one may make one's self easy; and so on through a host of proverbs that give a very poor idea of his intellect.

Of the national groups the Spanish is unquestionably the most remarkable. The number of Spanish proverbs is prodigious. In any other language 5000 or 6000 would be a large collection, but a Spanish MS. by Yriarte, the Royal librarian, which was in the Heber library, contained between 25,000 and 30,000, a number which, however incredible to others, is not at all surprising to those who know the proverbial aptitudes of the people and the language. In Spain almost everything has its proverb; every village of the plain, every herb of the field, has its virtues or vices put in a compendious shape for general circulation. And they are as racy as they are numerous, full of shrewd sense and knowledge of human nature, and rich in that grave, dry Spanish humour which never compromises itself by a descent into facetiousness. The Spaniard is, no doubt, naturally sententious, but the facilities offered by his rich, sonorous Castilian should not be overlooked; and among them must be reckoned its wealth in rhymes, consonant and assonant, of which there is such striking proof in the number and excellence of the Spanish rhyming proverbs. Language, it may be observed, plays an important part in proverbs. Take, for example, the Scotch 'Better a toom house than an ill tenant.' Compared with the English 'empty,' how much more effective is the Scandinavian 'toom,' to say nothing of the alliteration or inverted rhyme. The Basque proverbs, from which several of the Spanish are obviously derived, are of much the same character; and in both, but especially in the Basque, the resemblance to the proverbs of the East is very distinct. The Basque proverbs have not been as carefully collected as they deserve, and of course form only a small group; but, relatively to the Euskara-speaking population of a little over half a million, their numbers indicate a propensity to the use of the proverb as strong as the Spaniard's. The Italian proverbs, only less numerous than the Spanish, are more remarkable for wit, often bitter, than for humour; in the French, on the other hand, there is little or none of that brilliant wit and epigrammatic neatness of expression which distinguish French literature. But this is only what might be expected. French wit is the product of French culture, and proverbs are natural productions. Our own, including the Lowland Scotch, must be regarded as simply a subdivision of the great Teutonic group comprising the German, the Plattdeutsch, the Dutch, the Danish, the Swedish, and the Norwegian. Each of these has, of course, its own peculiar proverbs, but in each case the main body, it will be seen on comparison, belongs to a common stock. Next to Spain, the region richest in proverbs in Europe is probably that watered by the lower Elbe, and including Oldenburg, Hanover, Holstein, and Mecklenburg—the Anglo-Saxon country, in fact. Compared with other groups, the Celtic proverbs must be rated as poor. The Gaelic proverbs, as Nicolson's admirable collection shows and he himself admits, have been largely recruited from Norse and Lowland Scotch sources; and the purely Celtic are to a great extent made up of sayings in praise of Fingal, or expressive of the opinion which one clan has of another, or of itself. The Welsh proverbs gathered by Howell are very flat; and of the Irish Dr Nicolson observes that the wonder is they are so few, and those few so remarkably deficient in the wit for which our Hibernian cousins are specially distinguished—a remark certainly borne out by the specimens usually given, in which moral truisms of the copy-book order, like 'Virtue is everlasting wealth,' 'Wisdom excels all riches,' 'Falling is easier than rising,' have a decided predominance. Among the oriental proverbs the Arabic hold the first place in respect of quantity, and perhaps quality likewise, but the Persian and

Hindustani are also excellent, and in the Turkish, together with abundant worldly shrewdness, there is sometimes a vein of poetry that is very striking. It is questionable whether the 'tender beauty,' to use Trench's phrase, of our own proverb of the shorn lamb is not rivalled by its Turkish parallel, 'God makes a nest for the blind bird.'

The bibliography of proverbs is, of course, a subject which cannot be compressed within the limits of an article. Even the admirable work of M. Duplessis, *Bibliographie Parémiologique* (Paris, 1847), full as it is, has been outgrown by the proverb literature that has sprung up since its appearance; and Nopitzsch's *Literatur der Sprichwörter* (Nuremberg, 1833) is still more out of date. The oldest collections of proverbs—true proverbs, that is to say, not aphorisms or maxims of sages—are probably the French *Proverbes ruraux et rulgaux* and *Proverbes au Villain*, a significant title as indicating the recognised source of proverbial wisdom. Both of these are of the 13th century, and there are one or two others of the same sort almost as old. The Marquis of Santillana, the Spanish poet, statesman, and soldier, is the oldest collector of proverbs of whom we know anything. His collection of 625 'Proverbs that the old women repeat over the fire' was made at the request of John II. of Castile about the middle of the 15th century, but was not printed till 1508. The earliest German collections were those of Johann Agricola in 1528, and Sebastian Franck in 1541, for Bebel's 'Proverbia Germanica' (1508), being in Latin, cannot be counted. Of Italian proverbs the first genuine collection was the *Proverbi* of Antonio Cornazzano (Venice, 1518). Comparatively little attention has been paid to our own. John Heywood, the dramatist, in 1546 composed in verse *A dialogue conteyning in effect the number of all the proverbes in the English tunge*, which has a certain interest and value as the first attempt towards a collection in the language. George Herbert's *Jacula Prudentum* is, as its original title of *Outlandish Proverbs* implies, merely a collection of foreign proverbs in an English dress. Howell in 1659 collected a few which he appended to his *Lexicon Tetraglotton*, to take away the reproach against England 'that she is but barren in this point, and those proverbs she hath are but flat and empty.' The first deserving the name of a collection was Ray's in 1670, which, though faulty in system and arrangement, brought together a considerable number of genuine, racy, popular proverbs, and has passed through seven or eight editions. The best, that in Bohn's *Handbook of Proverbs* (1855), is supplemented by a copious 'Alphabet of Proverbs,' to which the companion volume, the *Polyglott of Foreign Proverbs* (1857), forms a useful adjunct. A later collection is Mr W. C. Hazlitt's (2d ed. 1882). Scotch proverbs have fared better. A collection by David Fergusson appeared in 1641, and a much larger one by Kelly in 1721, followed by Allan Ramsay's in 1737. Henderson's was published in 1832, and Hislop's in 1862. A collection of Gaelic proverbs was made by Donald Macintosh in 1785, and a more complete one by Alexander Nicolson in 1882. Trench's *Lessons in Proverbs* (1853) somewhat relieves the poverty of English proverb literature. In strong contrast to English neglect is the zeal of German collectors. Goedeke enumerates seventy-five names, and Duplessis more than thrice that number of works. A few of the more notable, after Agricola and Franck, are Lehmann, *Politischer Baumgarten* (1630); Siebenkees (1790); Wander, *Scheidemünze* (1832) and *Sprichwörter Lexicon* (1867); Korte (1837); Eiselein (1840); Simrock (1846); Sutermeister, *Schweizerische Sprichwörter* (1869); Binder, *Sprichwörterschatz* (1873); Schröder, *Plattdüdsche Sprückwörderschatz* (1875); Rheinsberg-Düringsfeld, *Sprichwörter der Germanischen und Romanischen Sprachen* (1872–75). The last is probably the most masterly work on proverbs ever written. It is not so much a collection as a concordance of proverbs, in which more than 1700 are traced through all the Teutonic and Latin languages and most of their dialects. The chief French collections are *Proverbes Communs* (15th century); Lebon, *Adages et Proverbes de Solon de Voye* (16th century); Meurier, *Trésor des Sentences* (1617); Oudin, *Curiositez Françoises* (1640); Panconcke, *Dictionnaire des Proverbes* (1749); Tuet, *Matinées Sénonaises* (1789); Le Roux de Lincy, *Livre des Proverbes Français* (1859; the best; over-elaborate in arrangement, but valuable for its introduction and appendices); Oihenart, *Proverbes Basques* (1657; reprinted 1847); Sauvé, *Proverbes de la Basse Bretagne* (1878); Lespy, *Proverbes du Pays de Bearn* (1876); Toselli, *Recuei de Prouverbi* (Nice, 1878).—Italian: Cynthio, *Proverbi* (1526); Pescetti, *Proverbi Italiani* (1598); Giusti, *Proverbi Toscani* (1853; new ed. by G. Capponi, 1884); Bonifacio, *Proverbi Lombardi* (1858); Tommaseo, *Proverbi Corsi* (1841); Pasqualigo, *Proverbi Veneti* (3d ed. 1882).—Spanish: *Refranes Famosissimos Glossados* (1509); Blasco de Garay, *Cartas en Refranes* (1545); Pedro Valles, *Libro de Refranes* (1549); Herman Nuñez de Guzman, *Refranes o Proverbios* (1555); Mallara, *Philosofía Vulgar* (1568); Palmireno, *El Estudioso Cortesano* (1587); Oudin, *Refranes Castellanos* (1605); Sorapan, *Medecina en Proverbios* (1616); Cejudo, *Refranes* (1675), *Refranes de la Lengua Castellana* (1815, from the Dictionary of the Academy); Collins, *Dictionary of Spanish Proverbs* (1822); U. R. Burke, *Spanish Salt* (1877; the proverbs in Don Quixote); Haller, *Altspanische Sprichwörter* (1883).—Portuguese: *Adagios, Proverbios, &c.* (1780–1841).—Dutch: Harrebomée, *Spreekwoorden* (1858–63).—Danish: Molbech, *Danske Ordsprog* (1850); Kok (1870); Grundtvig (1875).—Swedish: Reuterdahl, *Gamla Ordspråk* (1840); *Svenska Ordspråkboken* (1865).—Norwegian: Aasen, *Norske Ordsprog* (1856).—Icelandic: Dr H. Scheving (1847).—Flemish: Willems (1824).—Modern Greek: Negris, *Dictionary of Modern Greek Proverbs* (1834).—Russian: A selection in appendix to Duplessis (1847).—Arabic: Scaliger and Erpenius, *Proverbium Arabum Centuriæ Duæ* (1623); Burkhardt, *Arabic Proverbs* (1830; 2d ed. 1875); Freytag, *Proverbia* (1838–43); Landberg, *Proverbes et Dictons de la Province de Syrie* (1883).—Persian and Hindustani: Roebuck, (1824).—Bengali and Sanskrit: Morton (1832).—Behar: Christian (1891).—Turkish: Decourdemanche, *Mille et un Proverbes Turcs* (1878); *Osmanische Sprichwörter* (1865; K.K. Orient. Akad., Wien).—Chinese: *Hau Kiou Chooan, or the Pleasing History* (1761), contains a small collection.—Japanese: Steenackers and Ueda Tokunosuké, *Cent Proverbes Japonais* (1884).

Proverbs, The Book of, a canonical book of the Old Testament, holds the second place among the Hagiographa, coming immediately after Psalms. The Hebrew word *mashal*, translated in the title by *paroimia* in the LXX. and *proverbium* in the Vulgate, primarily means 'similitude,' and is applicable to any kind of allegory, simile, or comparison, especially when made for purposes of instruction; and every kind of didactic poetry is also included under the name. Typical instances of the use of the word occur in Ezek. xvii. 2 (LXX. *parabolē*, A.V. 'parable'), 1 Sam. x. 12 (LXX. *parabolē*, A.V. 'proverb'), Ps. xlix. 4 ('parable'), Isa. xiv. 4 (LXX. *threnos*, A.V. 'proverb'); it thus applies equally to that brief spontaneous product of popular wit or wisdom which in ordinary English parlance is most usually understood by the word 'proverb,' and also to that special kind of literary production which the Romans called *sententia*, the Greeks *gnomē*, and which is known to the modern French as the *maxim*. The Book of Proverbs as we now have it is made up of a number of originally separate collections; besides the general preface (i. 1–7), usually attributed to the author of chap. i.–ix., it consists of the following eight parts: (1) i. 8–ix. 18 has more appearance of plan, method, and free composition than any of the others, and is specially distinguished by the elaborateness with which its moral lessons are enforced. Its personification of wisdom as the first creation of God is 'one of the most remarkable and beautiful things in Hebrew literature,' and clearly marks it as belonging to a comparatively late phase of Hebrew thought not far removed from the beginnings of Alexandrian speculation. (2) x. 1–xxii. 16, headed 'the proverbs of Solomon,' consists of 376 miscellaneous distichs, mostly of the antithetic type, of which a good example is furnished by the opening verse of the collection. (3) xxii. 17–xxiv. 22 consists of

thirty-two moral precepts, six of which are distichs, seventeen in four lines, and the others of various forms, including a discourse or *mashal* of some length against drunkenness (xxiii. 29–35). An exhortation to heedfulness under instruction is prefixed (xxii. 17–21). (4) xxiv. 23–34 is superscribed 'These also are sayings of the wise,' and contains six sayings or precepts of a somewhat trite order, including, however, the familiar description of the sluggard and his vineyard. (5) xxv. 1–xxix. 27 has the heading 'These also are the proverbs of Solomon, which the men of Hezekiah, king of Judah, copied out.' Of the total number (127) 114 are distichs, six in four lines, and the rest irregular. This collection is generally considered by critics to contain more elements of high antiquity than the rest of the book, and is specially distinguished by the vigour, freshness, and originality of its observations and expressions. (6) xxx. consists of twelve sets of verses of various import, including some riddles of the Hebrew type. The somewhat obscure heading ought probably to run 'The words of Agur the son of Jakeh of Massa' (cf. Gen. xxv. 14; 1 Chron. i. 30, iv. 38), and the opening verses to be read (as in R.V. margin) 'The man said, I have wearied myself, O God, I have wearied myself, O God, and am consumed, for I am more brutish than any man, and have not the understanding of a man'—the despairing expression of a spirit that has exhausted its energies in the effort to reach a true knowledge of God. (7) xxxi. 1–9, 'The words of Lemuel, king of Massa (see above), wherewith his mother instructed him,' a warning against wine and women, and an exhortation to righteousness in judgment. (8) xxxi. 10–31, an alphabetical piece without superscription, consisting of twenty-two distichs in praise of the 'virtuous woman'—i.e. the wise, energetic, capable housewife. There are no data that enable us accurately to determine the relative ages of these eight portions. It seems not unreasonable to suppose that the book may have been brought into its present form by the writer of the first part (i.–ix.). It is not improbable that the book contains individual utterances of very great antiquity—as old as, and perhaps even older than, Solomon himself; but it is impossible to pick out these with certainty. There is no good reason for identifying the main collection (x. 1–xxii. 16), consisting as we have seen of 376 mashals, with the 3000 proverbs of Solomon mentioned in 1 Kings, iv. 32, though this has been done by Jerome; that x. 1–xxii. 16 was not before the compilers of xxv. 1–xxix. 27 is evident from the number of doublets contained in the latter series (cf., for example, xxv. 24 and xxi. 9; xxvi. 13 and xxii. 13; xxvi. 15 and xix. 24, and numerous other instances). It is probable that the present book was a slow and gradual growth; and that the process may have been carried on to a very late date is shown by the considerable variations between the Massoretic and Septuagint texts.

For a good account of the Book of Proverbs, with references to the literature of the subject, see Reuss, *Gesch. d. heil. Schriften Alten Testaments* (1890). The most convenient commentaries are those of Hitzig (1858), Bertheau (1847; new ed. by Nowack, 1883), and Delitzsch (1873; Eng. trans.). See also *The Speaker's Commentary*, and a homiletical work by Horton (1891).

Providence, a seaport and the semi-capital of the state of Rhode Island, the second city of New England and the twentieth in order of population in the United States, is situated at the head of navigation, on an arm of Narragansett Bay known as Providence River, 35 miles from the ocean and 44 miles by rail SSW. of Boston. It covers a wide area on both sides of the river, which, above its two bridges, expands into a cove, a mile in circuit, on the borders of which is a handsome park, shaded with noble elms. It is a city of large commerce, manufactures, and wealth, abounding with beautiful villas and gardens. Founded before the conventional type of American cities had been discovered, its streets are pleasantly irregular, and the site singularly uneven, rising in one place to 204 feet above high-water; and in one ward, much of which is still in farms, there are numerous hills and valleys. Among the many notable public buildings and institutions of Providence are a city hall, of granite, which cost upwards of $1,000,000, and has facing it the state's soldiers' monument; the state-house; the custom-house and post-office; the Athenæum, and the buildings of the Rhode Island Historical Society; the arcade and the Butler Exchange; a great number of churches, schools, and libraries, hospitals and asylums, including a noble charity known as the Dexter Asylum for the Poor; the Friends' Boarding-school (popularly, 'the Quaker College'); and Brown University, a Baptist institution, founded in 1764, and amply endowed: it has about 300 students, and ranks among the leading colleges of the United States. The city has lost most of its foreign trade, but instead it has become one of the great manufacturing centres of the country; two small rivers afford abundant water-power. The chief establishments are engaged in producing silver-ware, tools, stoves, engines, locomotives, cottons and woollens, corset-laces, shoe-laces, lamp-wicks, &c.; and besides there are scores of manufactories of jewellery, many bleaching-works, &c. Providence was settled in 1636 by Roger Williams. Pop. (1870) 68,904; (1880) 104,857; (1890) 132,146.

Province (Lat. *provincia*), a territory acquired by the Romans beyond the limits of Italy, and governed by a Roman Prætor (q.v.) or proprætor, or by a proconsul (see CONSUL). The senate decided which provinces were to be prætorian and which consular. As a rule the provinces were unmercifully plundered by the governors and the tax-collectors (*publicani*). Under Augustus there were twelve *imperial* provinces, requiring military occupation, and under the emperor's immediate control, and ten senatorial provinces, entrusted to senatorial management (see ROME). The provinces of France (q.v.) were superseded at the Revolution by the departments. The great governmental divisions of India, Canada, and other countries are often entitled provinces. The sphere of duty of an Archbishop (q.v.) is his province, usually consisting of several dioceses. The monastic orders are or were distributed in provinces of varying area; the *provincial*, in its monastic reference, is the superior of all the houses and all the members of a monastic order within any particular province. See GENERAL, MONACHISM.

Provins, a town of France (dept. Seine-et-Marne), by rail 59 miles SE. of Paris, has remains of ancient walls, flanked by ruined watch-towers. The most interesting feature is an ancient tower, built in the 12th century, vulgarly called Cæsar's Tower. The vicinity was long famous for its roses, and they are still cultivated to a considerable extent. There are numerous flour-mills and dye-works. Pop. 7888.

Provisional Order is an order granted, under the powers conferred by an act of parliament, by a department of the government, by the Secretary of State, or by some other authority, whereby certain things are authorised to be done which could be accomplished otherwise only by an act of parliament. The order does not receive effect, however, until it has been confirmed by the legislature. Till that time it is purely provisional; and even after it has been so confirmed and is in reality

an independent act, it retains the title of a provisional order. Provisional orders are most useful in facilitating the modification or extension of the provisions of general acts, so as to adapt them to the special necessities of particular districts. They may be obtained with much greater expedition and less cost than a private bill; the confirmatory act when unopposed may be obtained in a week or two, and has all the facilities of a government measure.

Provisions of Oxford. See MONTFORT.

Provisors, Statute of. The object of this statute, passed in the reign of Edward III. (1350), was to correct and put an end to the abuses which had arisen in the exercise of the papal prerogatives as to the disposal of benefices in England. See ENGLAND (CHURCH OF), Vol. IV. p. 357.

Provo City, capital of Utah county, Utah, is on the Provo River, between Utah Lake and the Wahsatch Mountains, and 46 miles by rail SSE. of Salt Lake City. It contains flour-mills, tanneries, &c. Pop. (1890) 5153.

Provost (Lat. *præpositus*, 'set over'), in Church Law, the chief dignitary of a cathedral or collegiate church, from which use the title has also been transferred to the heads of other bodies, religious, literary, or administrative. The name is also given to the superiors of certain religious houses of lesser rank, and the relation of which to the more important houses is analogous to that of the priory to the abbey. The head of a cathedral chapter was anciently the archdeacon. At present, in the Roman Catholic Church, cathedral chapters are presided over by provosts in Austria, Prussia, Bavaria, and England, but in other parts of Germany and in France by deans. In the Church of England the Dean (q.v.) is the chief officer of a cathedral; but the title of provost survives, alongside that of dean, in the Scottish Episcopal Church. In the Protestant Church in Germany, in the north especially, where several minor churches or chapels are attached to one chief church, the minister of the latter is called provost (*probst*). In England the heads of Oriel, Queen's, and Worcester colleges in the university of Oxford, and the head of King's College, Cambridge, are designated provost. The head of Eton College is also so called.

In Scotland the chief municipal magistrate of a city or burgh is called provost, the term corresponding to the English word mayor. The provost presides in the civic courts along with the bailies, who are his deputies (see BOROUGH). The provosts of Edinburgh, Glasgow, Aberdeen, Perth, and, since 1892, Dundee, are styled Lord Provost. The Lord Provost of Edinburgh is entitled to the prefix 'Right Honourable,' which may be attached not merely to the name of his office, but to his Christian name and surname. See ADDRESS (FORMS OF), PRECEDENCE. Within the city and liberties of Edinburgh the Lord Provost takes precedence next after members of the royal family.

Provost-marshal, in the Navy, is a person appointed to have charge of a prisoner before a court-martial, and until the sentence of the court is carried into execution. In the British Army the provost-marshal is an officer, appointed only abroad, to superintend the preservation of order, and to be, as it were, the head of the police of any particular camp or district. He has cognisance of all camp-followers, as well as of members of the army. Under the Army Act of 1881 he cannot as formerly inflict any punishment of his own authority, but may apprehend any offender and bring him before a court-martial. It may then be his duty to see the sentence of the court carried out.

Proxy (contracted for Procuracy), the agency of one person who acts as substitute for another. Every member of the House of Lords was formerly permitted, on obtaining a nominal license from the crown, to appoint another lord of parliament his proxy to vote for him in his absence. Only a spiritual lord could be proxy for a spiritual lord, and a temporal for a temporal lord, and no peer could hold more than two proxies at the same time. Proxies were never used in judicial business, or in committees of the House, nor could a proxy sign a protest. The practice of admitting proxies was discontinued in 1867. Shareholders in joint-stock companies may vote by proxy. Formerly princely persons were sometimes, for reasons of state or convenience, represented by deputy at their own marriages; but marriage by proxy is not recognised by the law of England. See MARRIAGE, Vol. VII. p. 58.

Prudentius, MARCUS AURELIUS CLEMENS, the most important of the Roman Christian poets, was born in the north of Spain in 348 A.D. Nothing is known regarding him except what he has himself told in a poetical autobiography prefixed to his works. From this we learn that he received a liberal education, practised as a pleader, discharged the functions of civil and criminal judge, and was ultimately appointed to a high office at the imperial court. His religious convictions came late in life, and he devoted the evening of his days to the composition of religious poetry. The year of his death is not known. Of his poems the chief are (1) *Cathemerinon Liber*, a series of twelve hortatory hymns, the first half for the different hours of the day, the latter half for different church seasons (Eng. trans. 1845); (2) *Peristephanon*, a collection of fourteen lyrical poems in honour of martyrs; (3) *Apotheosis*, a defence of the doctrine of the Trinity against heretics; (4) *Hamartigenia*, on the Origin of Evil, a polemic, in verse, against the Marcionites; (5) *Psychomachia*, on the Triumph of the Christian Graces in the Soul of a Believer; (6) *Contra Symmachum*, the first book a polemic against the heathen gods, the second against a petition of Symmachus for the restoration of the altar and statue of Victory cast down by Gratian; (7) *Diptychon*, a series of forty-nine hexameters, arranged in four verses, on scriptural incidents and personages. Bentley calls Prudentius 'the Horace and Virgil of the Christians,' which may be true enough if the critic only meant to say that he is the first of the early Christian verse-makers. See the article HYMN, Vol. VI. p. 46.

Editions are by F. Areval (Rome, 1788), reprinted in Migne's *Patrologia*, lix.–lx.; Obbar (Tübingen, 1845); and Dressel (Leip. 1860). See Brockhaus, *A. Prudentius* (1872); Ebert, *Geschichte der Christlich-Latein. Lit.* (vol. i. 1874); Faguet, *De A. Prudentii Clementis Carm. lyricis* (1883); and F. St John Thackeray, *Translations from Prudentius* (1890), with an excellent introduction on his life and times, language, metre, and style.

Prud'hommes, COUNCILS OF. See FRANCE, Vol. IV. p. 776.

Prunella. Skeat defines this material as 'a strong woollen stuff, originally of a dark colour,' Fr. *prunelle*, 'a sloe,' whence *prunella* in a Latinised form. We know this word chiefly from Pope's fine lines (*Essay on Man*, iv. 204):

> Worth makes the man, and want of it the fellow,
> The rest is all but leather or prunella.

To which passage, in the *Globe* edition, Mr Ward notes 'because clergymen's gowns were often made of this kind of stuff.'—The name Prunella is also given to a genus of plants of the natural order Labiatæ. Several species are natives of Europe; one only is found in Britain, *P. vulgaris*,

popularly known as Self-heal, a plant very frequent in moist and barren pastures, as it is also throughout most parts of Europe, central Asia, North America, and New Holland. It was at one time in considerable repute as a febrifuge. It is mildly aromatic and slightly astringent.

Prunes are dried fruit of the plum-tree (*Prunus domestica*), of the variety called *Juliana*, largely prepared in France, and exported thence. Great numbers come also from Bosnia and Servia.

Pruning, the removal of branches from fruit or forest trees, in order to the greater production of fruit, the improvement of the timber, or purposes of ornament. In pruning for ornamental purposes taste must chiefly be consulted, but reference must be made to what has been too little regarded in pruning of every kind—the nature or habit of the tree itself. Some trees will bear clipping into fantastic forms, which would be utterly destructive of others. Such forms, once esteemed as the finest ornaments of a pleasure-ground, or the neighbourhood of a mansion, are rejected by the simpler taste of the present age, and the 'topiarian art' has few admirers. Much may be done, however, by the removal of branches to give a finer form to ornamental trees; but in this, as in the pruning of trees grown for the sake of their timber, a great mistake is very generally committed in permitting branches to grow to a considerable size before they are cut off. It may be accepted as a general rule that the branches removed should be small in proportion to the bulk of the trunk. The removal of twigs and small branches is attended by no bad effects, and may be beneficial; but the removal of large branches is dangerous. The leaving of stumps or snags is an aggravation of the evil. They rot away and spoil the timber of the stem; indeed, a hole is not unfrequently formed, which may eventually lead to the rotting of the whole of the interior of the trunk of the largest oak. But in the case of forest trees pruning may with advantage be in great part avoided, by taking care to plant at proper distances, and thinning out the plantations sufficiently in early periods of their growth. In this way better timber is obtained and a greater produce from the land. Pines and firs scarcely ever require pruning, and are probably in almost all cases the worse of that which they get, except in the removal of those lower branches which have actually begun to decay. In other trees it is sometimes of importance to watch for branches that would divide the trunk, and to prevent the division, causing the main stem to ascend higher before it forms a crown; but to be of any use this must be done whilst the branches are still very young. Plantations should therefore be examined with a view to pruning, at intervals of not more than two years, after they are six or eight years old.

In orchards and fruit-gardens pruning is necessary, the object being not to produce timber, or the utmost luxuriance of trees, but fruit in the greatest perfection and abundance. The habits of each kind must be studied. Even in the pruning of gooseberry and currant bushes regard must be had to natural diversities, the gooseberry and black-currant producing fruit chiefly on young wood, whilst the red and white currant produce fruit chiefly on spurs from older branches. And so it is amongst trees; apricots, for example, producing fruit chiefly on young wood, cherries mostly on spurs, whilst plums produce both in the one way and in the other. The object of the gardener in pruning is to bring the tree into the condition best suited for producing fine fruit and in the greatest abundance; and to this the training of wall trees must also be accommodated. Sometimes, in order to produce particularly fine fruits for the improvement of the variety by seed, or for the sake of a prize at a horticultural exhibition, the gardener diminishes the number of branches likely to bear fruit beyond what would otherwise be desirable.

The general seasons of pruning are winter and spring; but some trees, particularly cherries and all other drupaceous fruit trees, are advantageously pruned in summer, as they then throw out less gum.

Pruning instruments are of various kinds—knives, axes, saws, bills of very various forms, &c.; and the *averruncator*, which may be described as a pair of scissors, one blade hooked or crooked, attached to a long handle, and working by a cord and pulley. It is scarcely used except for standard trees in gardens and orchards.

Prurigo is the name applied to a group of diseases of the skin, characterised by the presence of papules, scarcely distinguishable in colour from the normal skin, and so 'felt rather than seen,' accompanied by intense itching. One form of the disease, *prurigo senilis*, is met with in old people in consequence of the irritation caused by lice, and disappears when these are got rid of. In its most characteristic form, however, it almost always begins in childhood, and may persist through life: even when it is got rid of for a time it is very apt to recur. It chiefly affects the trunk and extensor surfaces of the limbs, and is worst in winter. The disease is aggravated by the scratching from which the sufferer cannot refrain, and the skin becomes thickened and often eczematous as well. Warm baths and soothing ointments externally, good feeding, cod-liver oil, and arsenic or quinine are generally found to give great relief, and often cure the disease entirely.

Prussia (Ger. *Preussen*), by far the largest and most important state in the German empire, is a kingdom embracing nearly the whole of northern Germany. It is bounded N. by the German Ocean, Jutland, and the Baltic; E. by Russia (and Russian Poland); S. by Austria, Saxony, the Thuringian states, Bavaria, Hesse-Darmstadt, and Alsace-Lorraine; W. by Luxembourg, Belgium, and the Netherlands. Prussia owns besides Hohenzollern (q.v.) and about thirteen other smaller exclaves or detached territories lying within the bounds of other German states. The total area is 136,000 sq. m., with (1895) 31,855,123 inhabitants—i.e. nearly two-thirds of the entire German empire, with about three-fifths of the population, equal to about one and one-tenth the size of the United Kingdom, or one-half of the state of Texas. The frontier line has a circumference of 4720 miles, of which 1025 miles are coast-line (770 miles on the Baltic, 255 miles on the German Ocean). The following are the provinces into which Prussia is divided:

	Area in sq. m.	Pop. in 1880.	Pop. in 1890.
East Prussia	14,446	1,933,936	1,958,132
West Prussia	9,964	1,405,898	1,433,480

Total	136,075¾	27,279,111	29,959,388

Omitting Berlin and Heligoland, the density of population ranges between 131 (Pomerania) and 452 (Rhenish Prussia) per sq. m. About one-fifth of the present area of Prussia has been acquired

since 1853, the largest gains being made after the victorious war of 1866. The Prussia of Frederick the Great embraced only 47,800 sq. m. when he ascended the throne, and 75,000 when he died. In 1819 the population was 10,981,934; in 1864, 19,254,649; in 1871, 24,689,252; in 1895, 31,855,123.

PHYSICAL FEATURES. *Mountains.*—The greater part of Prussia, more than two-thirds of its total area, belongs to the north European plain, while less than a third, chiefly in the south-west, can be described as hilly or mountainous. The division line between the two districts is roughly indicated by an irregular series of heights beginning with the Teutoburgerwald, to the east of the upper Ems, and the Weser Hills, on both sides of the upper Weser, and thence running towards the south-east in the Harz Mountains (q.v.), with the Brocken (3740 feet), and in the northern outliers of the Thüringerwald (Finsterberg, 3100 feet; Inselsberg, 3000 feet). Farther to the south-east this line of heights is continued by the Riesengebirge (q.v.), separating Prussian Silesia from Bohemia, and forming the northern ranges of the Sudetic system. None of these ranges rise above about 5000 feet; the Schneekoppe (5250 feet) in the Riesengebirge is the loftiest summit on Prussian territory. The western and south-western parts of the country, comprising Rhenish Prussia, Westphalia, and Hesse-Nassau, thus cut off from the sandy and heathy wastes of the north, are quite distinct in their physical character from the rest of Prussia. They are divided by the Rhine into two portions. On the west side of the river, between Aix-la-Chapelle and the Moselle, is the elevated plain known as the Hohe Veen and the Eifel, which has a mean elevation of 1600 feet, with a few higher hills (Hohe Acht, 2490 feet). South of the Moselle, and parallel with that river, stretches the Hunsruck, with an average height of 1200 to 1500 feet, and farther south is the Hardt, the name here given to the northern extremity of the Vosges. On the east side of the Rhine the Sauerland, between the Ruhr and the Sieg, with the Rothaar or Rotlagergebirge, is succeeded farther south by the Westerwald (Fuchskauten, 2155 feet), between the Sieg and the Lahn, and by the Taunus (Feldberg, 2885 feet), between the Lahn and the Main. To the south of the Taunus, famous for its mineral springs, lies the fertile valley of the Main, while to the east the Vogelsberg, chiefly, however, in Hesse, forms a link with the Hohe Rhön (Wasserkuppe, 3115 feet), which may be regarded as an outlier of the Thüringerwald. The soil is generally poor in these districts, though they possess special sources of wealth in their iron and coal mines. The level country between the Rhone and the Maas, bordering the Eifel, is, however, extremely fertile; and Hesse-Cassel is particularly fruitful, cereals of all kinds growing abundantly. The great northern plain, which occupies the rest of the kingdom, is varied by two terrace-like elevations already described under GERMANY (Vol. V. p. 172). The surface is diversified with numerous lakes, especially in the east, on what are known as the Pomeranian and East Prussian Lake-plateaus, but none of them is more than 20 sq. m. in area, though altogether they are estimated to cover more than 300 sq. m. The soil, consisting chiefly of loose sand interspersed with a large number of erratic blocks of granite, is sterile, covered in many places with heaths and belts of stunted pines. On the northern slope, terminating on the shores of the Baltic, there are several fertile districts, more especially along those rivers which have been carefully embanked, as the Niemen and the Vistula. The southern elevation of the Prussian plain, running between the Polish mountains of Sandomir in the south-east and the Elbe between Magdeburg and Burg in the north-west, attains a height of about 1000 feet near Breslau on the Oder, where it is known as the Trebnitz Heights. Its general character is more fertile than the northern elevation; while the country between the two is, for the most part, extremely sterile. It includes the sandy waste in which Berlin, the capital, is situated. South of this tract, and in Silesia and Prussian Saxony, the country is fertile, including some of the most productive grain-growing districts of Prussia. Hanover has much the same character. Great marshes or peat-moors cover the north and north-west districts; but the valleys that lie among the Harz Mountains in the south are often fertile, and well adapted for agriculture. The coasts are low, and require to be protected from the overflowing of the sea by embankments and dykes. Sleswick-Holstein, to the north of the Elbe, is in part sandy and heathy, like the plain of Hanover, but it has also numerous marshes.

Rivers.—The northern plain is watered by five large rivers—the Niemen, Vistula, Oder, Elbe, and Weser—all of which rise beyond the borders of the kingdom, and the Pregel, Eider, and Ems, which are exclusively Prussian. In the west the chief river is the Rhine, which enters Prussia at Mainz, and thence flows north through a narrow valley noted as one of the most picturesque parts of Germany. The Rhine, which is navigable throughout its entire course in Prussian territory, receives numerous tributaries—as the Lahn, Wied, Sieg, Wupper, Ruhr, Lippe, Berkel, and Vechte, on the right, and on the left the Ahr and the Moselle or Mosel, the latter of which is navigable for more than 150 miles within the Prussian dominions. The Weser, Elbe, Oder, and Vistula, as also the Spree and Havel, affluents of the Elbe, are of high importance for the inland navigation of Prussia, and are each discussed in special articles. Altogether Prussia is said to possess 119 navigable rivers, besides nearly fifty others that may be used by rafts, and ninety navigable canals. Of the last named, which form a network connecting the chief rivers of north Germany, the most important are the Bromberger, the Finow, the Friedrich-Wilhelms, and the Eider Canals.

Climate.—The climate of Prussia presents great differences in the eastern and western provinces, the former being exposed to heavy snowstorms in winter and great drought in summer, while the latter have milder winters and a greater rainfall. At Berlin the annual mean temperature is 48° F.; on the Rhine it is 49° (summer, 63°; winter, 34°); in the east provinces and among the mountains it is below 43° (summer, 61°; winter, 25°).

Productions.—Agriculture and the rearing of cattle constitute the principal sources of employment and wealth of the rural population of the entire monarchy, and the state has hitherto directed its unremitting attention to the furtherance of the one and the improvement of the other; abrogating onerous land-taxes, advancing money to landowners, encouraging agricultural institutions, introducing approved breeds of animals and improved farm instruments, &c. Rather less than one-half, or 12,000,000, of the population of the kingdom are engaged in agriculture as their sole or chief occupation. Of the total area 50 per cent. is occupied by arable land, 9½ per cent. by meadows, and 11 per cent. by pasturage. Large estates, as a rule, are only to be found in the eastern and least populated provinces of the monarchy. Rye, wheat, oats, barley, peas, millet, rape-seed, maize, linseed, beet-root, potatoes, tobacco, flax, hemp, hops, chicory are extensively cultivated. The finest grain districts are the Börde, near Magdeburg, the low lands on the Wartha and Netze, and on the Plöne and Madüe

lakes, the north-eastern parts of Pomerania, the island of Rügen, the valleys of the Oder in Silesia, of the Saale, Moselle, Saar, and parts of Hesse-Nassau. Magdeburg is the centre of the beet-root sugar industry. Western Prussia is noted for its excellent fruits and vegetables, and its provinces stand pre-eminent for their wines. Nassau is specially famous for its Rhine wines. The forest-lands, which are chiefly in East Prussia, Posen, Upper Silesia, Westphalia, Southern Hanover, and Hesse-Nassau, are of great value and considerable extent, occupying an area of 10,000,000 English acres. The mineral products of Prussia include coal, iron, lead, zinc, copper, cobalt, antimony, manganese, arsenic, sulphur, alum, nickel, black lead, baryta, gypsum, slate, lime, freestone, salt, amber, agate, jasper, onyx, &c. Prussia yields about one-half of the annual zinc production of the world; and of the total output of coal in Germany, about three-eighths of that of the United Kingdom, Prussia produces 93 per cent. The chief coalfields are in Silesia, Westphalia, and Rhenish Prussia, which are at the same time the chief industrial provinces of the kingdom. The region of the Harz in Hanover is also famous for its mining industries. All metals, salt, precious stones, and amber found along the Prussian coast from Danzig to Memel belong to the crown. Prussia has upwards of 100 mineral springs, of which the most noted and efficient are the sulphur baths of Aix-la-Chapelle and Ems, the iron springs of Schwalbach, Wilhelmsbad, Driburg, and the hot and saline baths of Reinerz, Landeck, Flinsberg, Freienwalde, Lauchstedt, Wiesbaden, Schlangenbad, and Selters. East Prussia is noted for its royal studs, and the excellent breed of horses which it now raises, and of which large numbers are annually exported. Westphalia enjoys a special reputation for the excellence of its hams and pork, Pomerania for its smoked geese, and Brandenburg and Hanover for honey and wax. Fish of all sorts are abundant in the rivers and numerous lakes; seals are taken in the Baltic. The wooded districts abound in game of every kind, pheasants, partridges, and wild geese being often found in enormous quantities. Besides stags, fallow-deer, wild boars, foxes, otters, weasels, polecats, martens, badgers, hares and rabbits, the lynx, bear, eagle, and beaver are occasionally met with.

Manufactures.—The principal manufactures are linens, for which certain districts of Silesia, Prussian Saxony, and Brandenburg enjoy a European celebrity; while of late years the cotton manufactories, worked by steam, have maintained a successful rivalry with the older linens, worked by hand-looms. Besides these there are numerous manufactories of silk, wool, mixed cotton and linen fabrics; including fine shawls and carpets in Brandenburg, stockings and ribbons in the Rhenish provinces, where, as well as in Westphalia and Hesse-Nassau, the flax, hemp, and silk and cotton thread is mainly prepared for the manufacturers. These districts, moreover, stand foremost in regard to the preparation and manufacture of iron, steel (the steel and gun works of Krupp, at Essen, being world-famous), and other metallic wares, paper, leather, soap, oil, cigars, and tobacco, and for the number of their distilleries and breweries; while Saxony and Silesia have the largest number of chicory, starch, beet-root, gunpowder, and glass works. Berlin and Elberfeld rank as the two most important centres of manufacture on the Continent. In 1895–96 there were 307 beet-root sugar factories in Prussia, which produced 1,212,578 metric tons of raw sugar. In that year the total value of the minerals produced in the kingdom was £23,700,000 (of which nearly two-thirds came from the Rhineland and Westphalia); while the mineral produce of the German empire was £37,600,000.

Commerce.—The commerce of Prussia is materially facilitated by her central European position, and the network of river and canal navigation, which makes her territories the connecting medium between several of the great European states, and which, with 15,000 miles of railway, 40,500 miles of public roads (all, or nearly all, formed since the time of Frederick the Great), and a coast-line of 1000 miles, gives her a free outlet to the rest of the world. The Prussian mercantile marine in 1889 numbered 2255 vessels of 354,213 tons. The chief ports are Memel, Pillau, Königsberg, Danzig, Colberg, Swinemünde, Stettin, Wolgast, Stralsund, Kiel, Flensborg, Altona, Harburg, Geestemünde, Leer, and Emden. The principal commercial towns are Berlin, Königsberg, Breslau, Barmen, Elberfeld, Danzig, Posen, Stettin, Cologne, Magdeburg, Aix-la-Chapelle, and Frankfort-on-the-Main. Annual fairs are still held at Breslau, Magdeburg, and Frankfort-on-the-Oder.

The money, measures, and weights of Prussia are those in use throughout the German empire. In accordance with the law of 1872 the *mark* is the unit of reckoning, and has gradually displaced Thalers (q.v.) and silbergroschen. The Prussian or Berlin Bank, founded in 1765, with numerous branches in the provinces, is the most important of those banks which possess the right of issuing notes.

Religion, &c.—The dominant religion is Protestantism, and since 1817 the Lutheran and Reformed Churches have been united under the head of one common evangelical church. Everything connected with the external administration of church matters is under the control of the minister of public instruction and ecclesiastical affairs, but every religious community manages its own internal concerns; the Protestant churches acting in conjunction with consistories or boards appointed by the government, one of which exists in each province, under the direction of the upper president, or provincial governor, and a clerical superintendent-general, who in Posen and Pomerania bears the title of bishop; while the Roman Catholic Church is directed by the two archbishops of Posen and Gnesen, and Cologne, under whom stand the four bishopries of Culm, Münster, Paderborn, and Treves. The four episcopal sees of Breslau, Ermeland, Osnabrück, and Hildesheim are directly under the jurisdiction of the pope, while the district of Glatz, in Silesia, belongs to the archbishopric of Prague; Katscher, in Upper Silesia, to that of Olmütz; and Fulda and Limburg to that of Freiburg. The results of the census of 1885, as regards the numbers of the religious bodies, are as follows: the Protestants of Prussia numbered 18,244,405 (64·4 per cent. of the pop.); Roman Catholics, 9,621,763 (33·9 per cent.); Jews, 366,575 (1·29 per cent.). Roman Catholics are most numerous in Hohenzollern (95 per cent.), Rhenish Prussia (71 per cent.), Posen, Silesia, Westphalia, and West Prussia. The higher Roman Catholic clergy are paid by the state, the parochial clergy chiefly by endowments. For the *Kultur-kampf*, see the article GERMANY, Vol. V. p. 185.

Education.—Education is compulsory in Prussia between the ages of six and fourteen, and its management and direction are under the control of the state. In no country are better or ampler means supplied for the diffusion of knowledge among all classes of the community. Prussia has ten universities—viz. Königsberg, Berlin, Greifswald, Breslau, Halle, Göttingen, Münster, Bonn, Kiel, and Marburg, which in 1889–90 numbered above 1240 professors and teachers and 15,770 students. The educational system has already been described

under GERMANY, Vol. V. p. 176. In 1896 there were in Prussia 36,000 elementary schools, with 82,200 teachers and 5,236,820 pupils. The management of the elementary national schools is in the hands of the local communities; but the state appoints the teachers, and in part pays their salaries, the remainder being supplied by the public. In addition to the libraries of the several universities there is the Royal Library at Berlin, with 800,000 volumes and about 15,000 MSS. Among the numerous scientific, artistic, and literary schools and societies of Prussia the following are some of the more distinguished: the Academy of Arts, founded in 1700; the Royal Museum of Arts; the Academy of Sciences; the Natural History, Geographical, and Polytechnic Societies of Berlin; the Antiquarian Society of Stettin; the Breslau Natural History and Historical Societies; &c.

Justice.—Till lately the *Code Napoléon* was in force in the Rhenish provinces, and in Hither-Pomerania the common German law; but in other parts of the kingdom the Prussian code, compiled under Frederick the Great's direction, was followed. A new penal code was promulgated in 1850, by which all pre-existing seigniorial, municipal, or ecclesiastical rights of decreeing punishments were unconditionally abrogated. A partial codification was brought about in 1862, and in 1869 a code of commercial law valid for the North German Confederation. Since the establishment of the empire imperial law has precedence of that peculiar to the various states in a large number of subjects. Universal criminal and commercial codes are now in force for the whole empire, and a universal civil code has been prepared. A common judicature bill for the empire was passed in 1879. Prussia has sixteen *Oberlandes-gerichte* or provincial courts, one or more in each province. Connected with that sitting at Berlin is the Privy-council of Justice, which has jurisdiction over the royal family and the princely houses of Hohenzollern. The supreme tribunal of the empire has been established, not at Berlin, but at Leipzig, in Saxony.

Army, Navy, &c.—In 1899 the strength of the Prussian army on a peace footing, according to official returns, numbered 453,000, of whom 53,000 were cavalry and 64,000 artillery. The army consists of the regular troops and the Landwehr (q.v.), and in time of war an extra force can be called up under the title of the landsturm. Every able-bodied male Prussian is liable to be called upon to serve between twenty and thirty-nine years of age (see GERMANY). Clergymen of the Roman Catholic and Evangelical churches and indispensable supporters of families are exempt. Great care is bestowed on the education and military training of officers and men; and, besides numerous admirable academies, there are several good schools of operative and veterinary surgery, &c. connected with the educational department of the army. The navy of the new German empire is the navy of Prussia. See GERMANY.

Constitution, &c.—Prussia was an absolute monarchy till the crisis of 1848, when the decided movement in favour of liberal views compelled the king to convoke a national assembly, and submit to the establishment of a constitutional form of government, which has been repeatedly modified. The national representative body consists of two bodies: (1) an upper chamber (*Herrenhaus*, or 'House of Lords'), which is now composed of the princes of the royal family who are of age, the chiefs of the mediatised princely houses recognised by the Congress of Vienna, numbering sixteen in Prussia, the heads of the territorial nobility (about fifty), life-peers chosen by the king from the class of rich landowners, manufacturers, and 'national celebrities,' a titled representative chosen by all landowners in each of the Prussian provinces, representatives of the universities, the burgomasters of all towns having more than 50,000 inhabitants, and an indefinite number of members appointed by the king for life or for a limited period; (2) a lower chamber (*Abgeordnetenhaus*, or 'Chamber of Deputies'), composed of 432 members, 352 for the old kingdom and 80 for the provinces annexed in 1867. Every Prussian who has attained his twenty-fifth year, and who has a municipal vote, has also a parliamentary vote, but not a direct one. Out of every 250 *Urwähler*, or electors in the first instance, is chosen a *Wahlmann*, or direct elector. This is the man who, strictly speaking, votes for a member of parliament. Representatives are elected for five years, and each receives twenty marks per diem, the refusal of which is illegal. In addition to this general house of assembly there are representative bodies for the provinces, communes, and circles, which debate and legislate in regard to local matters within their several departments. The executive council of state is composed of eleven ministers appointed by the king, and holding office without reference to the comparative strength of political parties. The president of the council has a salary of £2700, each of the other ministers receives £1800. By the modified constitution of 1850 all exclusive privileges arising from titles or station are abrogated, and perfect equality in the eye of the law fully recognised; liberty of the subject guaranteed in regard to religious persuasion, the right to hold meetings unarmed within closed doors, and become members of societies; immunity from domiciliary visits, and inviolability of letters, &c. The monarchy is hereditary in the male line. The sovereign and royal family must profess the evangelical confession of faith. The king, who is not responsible for the measures of his government, and whose decrees require the counter-signatures of his ministers, exercises the executive power, nominates and dismisses the ministry, summons and dissolves the chambers, orders the promulgation of the laws, is commander-in-chief of the forces, has the right of proclaiming peace and war, granting reprieves, &c. He bears the titles of King of Prussia, Markgraf of Brandenburg, Sovereign-duke of Silesia, Prince of Orange, Grand-duke of Pomerania and the Lower Rhine, besides a host of lesser titles. The title 'German Emperor,' by which he is now best known, is not, of course, a Prussian dignity. The eldest son of the king bears the title of Crown-prince. The ordinary royal residences are the palaces at Berlin, Potsdam, and Charlottenburg. The royal domains were ceded to the state by Frederick-William III. in 1820, on condition of a rental of 2½ million thalers being paid first from them for the king and his family, which, however, has been increased in 1859, 1868, and 1889 by means of a *Krondotation* ('crown-allowance') to £770,550.

In the year 1898–99 the budget-estimate of the receipts was 2,187,527,384 marks (£109,376,370), just balanced by the expenditure. The total national debt bearing interest was 6,485,222,000 marks (£324,261,100), or about £10, 3s. per head of the population. The direct taxes are an income-tax, land-tax, house-tax, class-tax, and trading-tax, and amount to about 5s. 6d. per head. The income-tax yields about 1s. 5d. per head of the population.

Population, Races.—About seven-eighths of the population of Prussia are Germans. Of the Slavonic tribes the most numerous are Poles, numbering 2½ millions. In Brandenburg and Silesia there are about 85,000 Wends; in East Prussia, upwards of 150,000 Lithuanians; Western Prussia has rather

more than 10,000 Walloons, using the French language; intermixed in its generally German population Silesia has 55,000 Czechs or Bohemians; Sleswick-Holstein, 140,000 Danes—making in all about 3 millions who do not use the German language, or who employ it only as secondary to their native tongues.

Ranks, Classes.—Three distinct hereditary classes are recognised in Prussia—viz. nobles, burghers, and peasants. To the first belong nearly 200,000 persons, including the higher officials of the state, although that number does not comprise the various mediatised houses, of which sixteen are Prussian, and others belonging to different states, but connected with Prussia by still existing, or former territorial possessions. The burgher class includes, in its higher branches, all public office-bearers, professional men, artists, and merchants; while the peasantry—to which belong all persons engaged in agricultural pursuits—are divided into classes, depending on the number of horses employed on the land, &c.

History.—The lands bounded by the Baltic, which now form part of Prussia, were early occupied by Slavonic tribes, nearly allied to the Letts and Lithuanians. It is conjectured that they were visited by Phœnician navigators in the 4th century B.C.; but, beyond the fact of their having come into temporary conflict with the Goths and other Teutonic hordes prior to the great exodus of the latter from their northern homes, little is known of the people till the 10th century, when they first appear in history under the name of Borussi, or Prussians. In 997 Bishop Adalbert of Prague suffered martyrdom at their hands while endeavouring to convert the people to Christianity. Boleslas, Duke of Poland, succeeded, however, about 1018, in compelling them to submit to baptism and subjection. After many futile attempts on the part of the people to throw off the yoke of Christianity and foreign domination, they finally made a successful stand against Boleslas IV. of Poland in 1161, and for a time maintained a rude and savage kind of independence, which the disturbed condition of Poland prevented its rulers from breaking down. The fear of losing their freedom if they adopted Christianity made the Prussians obstinately resist every effort for their conversion; and it was not till the middle of the 13th century, when the knights of the Teutonic order began their 'famous' crusade against them (see TEUTONIC KNIGHTS), that the Christian faith was established among them. The inroads of the pagan Prussians on the territories of their Christian neighbours, and their advance into Pomerania, were the exciting causes of this important movement. The knights of the order, when appealed to by Conrad, Duke of Masovia, to aid in the subjection of the heathen, gladly promised their services on condition of being permitted to retain possession of the lands which they might conquer; and, having entered the Prussian territories in considerable numbers, they entrenched themselves in Vogelsang and Nessau in 1230, and at once entered upon the conquest of Prussia. For half a century the belligerent brotherhood were engaged in war with the people—winning lands and souls by hard fighting—until at length in 1283 they found themselves undisputed masters of the country, which they had both civilised and Christianised after a fashion—that is to say, by almost exterminating the pagan population. During this period of struggle the knights founded the cities of Thorn, Kulm, Marienwerder, Memel, and Königsberg, repeopled the country with German colonists, encouraged agriculture and trade, and laid the foundation of a well-ordered, prosperous state. The unhappy wars between the knights and the Poles and Lithuanians, together with the moral degeneracy of the order, led, in the 14th and 15th centuries, to the gradual decline of their supremacy. In 1454 the municipal and noble classes, with the co-operation of Poland, rose in open rebellion against the knights, who were finally compelled to seek peace at any cost, and obliged in 1466 to accept the terms offered to them by the treaty of Thorn, by which West Prussia and Ermland were ceded by them unconditionally to Poland, and the remainder of their territories declared to be fiefs of that kingdom. In 1511 the knights elected as their grand-master the Markgraf Albert of Anspach and Baireuth, a kinsman of the king of Poland, and a scion of the Frankish line of the Hohenzollern family. Although his election did not immediately result, as the knights had hoped, in securing them allies powerful enough to aid them in emancipating themselves from Polish domination, it was fraught with important consequences to Germany at large, no less than to the order itself. In 1525 the grand-master was acknowledged Duke of Prussia, which was converted into a secular duchy (afterwards known as East Prussia), and renounced the Roman Catholic religion for Lutheranism, his example being followed by many of the knights. The country made rapid advances under the rule of Albert, who improved the mode of administering the law, restored some order to the finances of the state, established schools, founded the university of Königsberg (1544), and caused the Bible to be translated into Polish, and several books of instruction to be printed in German, Polish, and Lithuanian. His son and successor, Albert Frederick, having become insane, a regency was appointed. Several of his kinsmen in turn enjoyed the dignity of regent, and finally his son-in-law, Johann Sigismund, elector of Brandenburg, after having held the administration of affairs in his hands for some years, was, on the death of the duke in 1618, recognised as his successor, both by the people and by the king of Poland, from whom he received the investiture of the duchy of Prussia, which, since that period, has been governed by the Hohenzollern-Brandenburg House.

Here it will be necessary to retrace our steps in order briefly to consider the political and dynastic relations of the other parts of the Prussian state. In 1134 the North Mark, afterwards called the Altmark, a district in the west of the Elbe and north-east of the Harz, was bestowed upon Albert the Bear of Luxembourg, who extended his dominion over the marshy region near Brandenburg and Berlin (the Mittelmark), and assumed the title of Markgraf of Brandenburg. During the next two or three centuries his immediate descendants advanced still farther eastward, beyond the Oder into Farther Pomerania. On the extinction of this line, known as the Ascanian House, in 1319, a century of strife and disorder followed, until finally Frederick VI., count of Hohenzollern, and markgraf of Nuremberg, became possessed, partly by purchase and partly by investiture from the Emperor Sigismund, of the Brandenburg lands, which, in his favour, were constituted into an electorate. This prince, known as the Elector Frederick I., received his investiture in 1417. He united under his rule, in addition to his hereditary Franconian lands of Anspach and Baireuth, a territory of more than 11,000 sq. m. His reign was disturbed by the insubordination of the nobles, and the constant incursions of his Prussian and Polish neighbours, but by his firmness and resolution he restored order at home and enlarged his boundaries. Under Frederick's successors the Brandenburg territory was augmented by the addition of many new acquisitions, although the system of granting appanages to the younger members of the reigning

house, common at that time, deprived the electorate of some of its original domains. The *Dispositio Achillea*, however, which came into operation on the death of the Elector Albert Achilles (1470–86), while it separated Anspach and Brandenburg, legally established the principle of primogeniture in both. The most considerable addition to the electorate was the one to which reference has already been made, and which fell to the Elector John Sigismund through his marriage in 1609 with Anne, daughter and heiress of Albert Frederick the Insane, Duke of Prussia. In consequence of this alliance the duchy of Cleves, the countships of Ravensberg, the Mark, and Limburg, and the extensive duchy of Prussia, now known as East Prussia, became incorporated with the Brandenburg territories, which were thus more than doubled in area.

The reign of John Sigismund's successor, George-William (1619–40), was distracted by the miseries of the Thirty Years' War, and the country was alternately the prey of Swedish and imperial armies; and on the accession of George-William's son, Frederick-William (q.v.), the 'Great Elector,' in 1640, the electorate was sunk in the lowest depths of social misery and financial embarrassment. But so wise, prudent, and vigorous was the government of this prince that at his death in 1688 he left a well-filled exchequer, and a fairly-equipped army of 38,000 men; while the electorate, which now possessed a population of one and a half million and an area of 43,000 sq. m., had been raised by his genius to the rank of a great European power. His successors Frederick I. (q.v.; 1688–1713) and Frederick-William I. (1713–40) each in his own way increased the power and credit of Prussia, which had been in 1701 raised to the rank of a kingdom. The latter monarch was distinguished for his rigid economy of the public money and an extraordinary penchant for tall soldiers, and left to his son Frederick II. (q.v.), Frederick the Great, a compact and prosperous state, a well-disciplined army, and a sum of nearly nine million thalers in his treasury. Frederick II. (1740–86) dexterously availed himself of the extraordinary advantages of his position to raise Prussia to the rank of one of the great political powers of Europe. In the intervals between his great wars he devoted all his energies to the improvement of the state, by encouraging agriculture, trade, and commerce, and reorganising the military, financial, and judicial departments of the state. By his liberal views in regard to religion, science, and government he inaugurated a system whose results reacted on the whole of Europe; and in Germany more especially he gave a new stimulus to thought, and roused the dormant patriotism of the people. Frederick was not over-scrupulous in his means of enlarging his dominions, as he proved by sharing in the first partition of Poland in 1772, when he obtained as his portion nearly all West Prussia and several other districts in East Prussia. His nephew and successor, Frederick-William II. (1786–97), aggrandised his kingdom by the second and third partitions of Poland in 1793 and 1795. Frederick-William III. (q.v.; 1797–1840), who had been educated under the direction of his grand-uncle, Frederick the Great, succeeded his father in 1797, at a time of extreme difficulty, when continental rulers had no choice beyond being the opponents, the tools, or the victims of French republican ambition. By endeavouring to maintain a neutral attitude Prussia lost her political importance, and gained no real friends, but many covert enemies. But the calamities which this line of policy brought upon Prussia roused Frederick-William from his apathy, and, with energy, perseverance, and self-denial worthy of all praise, he devoted himself, with his great minister Stein, seconded by Count Hardenberg, to the reorganisation of the state. In the years 1806–10 Prussia underwent a complete domestic reorganisation; and after the battle of Waterloo, which restored to Prussia much of the territory lost at the peace of Tilsit in 1807, the career of progress was continued. Trade received a new impulse through the various commercial treaties made with the maritime nations of the world, the formation of excellent roads, the establishment of steam and sailing packets on the great rivers, and at a later period through the organisation of the Zollverein (q.v.), and through the formation of railways. The most ample and liberal provision was made for the diffusion of education over every part of the kingdom, and to every class. In like manner, the established Protestant Church was enriched by the newly-inaugurated system of government subvention, churches were built, the emoluments of the clergy were raised, and their dwellings improved; but, not content with that, the king forcibly united the Lutheran and Reformed Churches in 1817, a high-handed act most fruitful in discontent and difficulties. This tendency to over-legislation has long been the predominating evil feature of Prussian administration; and the state, without regard to the incongruous elements of which it was composed, was divided and subdivided into governmental departments, which, in their turn, under some head or other, brought every individual act under governmental supervision, to the utter annihilation of political independence. The people soon perceived that this administrative machinery made no provision for political and civil liberty, and demanded of the king the fulfilment of the promise he had given in 1815 of establishing a representative constitution for the whole kingdom. This demand was not acceded to by the king, and its immediate fruits were strenuous efforts on his part to check the spirit of liberalism. Siding with the pietists of Germany, he introduced a sort of Jesuitical despotism, which was continued by his successor, Frederick-William IV. The Landstände or provincial estates, organised in accordance with the system of the middle ages, were the sole and inadequate mode of representation granted to Prussia in this reign, notwithstanding the pledge made to the nation for a full and general representative government. The accession of Frederick-William IV. (1840–61) seemed to open a better prospect to the friends of constitutional freedom. A political amnesty was proclaimed, religious toleration was announced, and a contest betwixt the crown and the pope, in which the first signs of the coming Kulturkampf may be traced, was brought to a close by concessions on the part of the king. Frederick-William, however, was an enthusiastic upholder of the divine right of kings, and it soon became apparent that he was in no way prepared to follow up his vague promises of political liberty by sharing political power with the people. The bureaucratic spirit of over-governing became daily more and more irksome to the nation, and it was evident that a constitutional struggle was inevitable. The king and his advisers, underrating the importance of the movement of 1848 in Germany, thought they had satisfied the requirements of the hour by granting a few unimportant reforms and by making equivocal promises of future concessions. A collision betwixt the troops and the citizens of Berlin, in which blood was shed, awoke the king to the full gravity of the crisis, and he hastened to allay the general discontent by the nomination of a liberal ministry, the recognition of a civic guard, and the summoning of a representative chamber to discuss the proposed constitution. The conversion of the monarch to liberalism was but temporary; and although, after

much obstruction, a constitution, superseding the old Prussian estates by a representative parliament, was promulgated in January 1850, it was repeatedly modified in the following years, until few of its democratic features were left. Frederick-William had early distinguished himself and delighted many Germans, both within and without Prussia, by his patriotic utterances in favour of a new united Germany. He was deeply chagrined when in 1848 the national assembly at Frankfort, influenced by Austrian jealousy of the military strength of Prussia, declined to accept him as the national leader, and elected instead the Archduke John of Austria as lieutenant-general of Germany. Yet, when in the following year he was offered the imperial crown, he found himself unable to face the responsibility of accepting it. He hesitated to make so important a move in the contest with Austria for the hegemony of Germany. The later years of this reign were characterised by great advances in the material prosperity and internal improvement of the country. Extensive lines of railway and post-roads were opened, the river navigation greatly facilitated, treaties of commerce formed with foreign countries, and great expansion given to the Prussian and North German Zollverein (q.v.), the army put upon a footing of hitherto unprecedented efficiency of arms and artillery, and the educational system of the country still further developed. William I. (1861–88), who became German emperor in 1871, had been regent of the kingdom since 1858, owing to the insanity of his brother, the late king. William was no more a lover of constitutional, or at least of popular, liberty than any of his predecessors; and in his opposition to the progress of the popular movement, in so far as it aimed at interference with the regal power, he was powerfully aided by his great adviser Bismarck (q.v.), who became prime-minister in 1862 and imperial chancellor in 1871. The successful wars with Austria (1866) and France (1870–71), which so enhanced the prestige of Prussia and which resulted in the united Germany of to-day, are described at GERMANY. Since the king of Prussia became German Emperor the history of Prussia has been practically merged in the history of Germany. After the brief reign of Frederick III. (March 9 to June 15, 1888), his son, William II. (q.v.), ascended the throne. While still adhering to the military policy of his grandfather, and still cherishing a more or less exalted belief in the divine right of kings, the young monarch has shown himself able to realise the importance of the great social questions of modern times, and ready to deal with them in a decided yet sympathetic manner. The advanced, and in some respects socialistic 'labour-policy' of the emperor, unfolded at a labour-conference of representatives of the great powers in Berlin 1890, and the abolition of the anti-socialist laws led to the resignation by Prince Bismarck of all his ministerial functions in March 1890, as well in the kingdom as in the empire; and no subsequent Prussian minister has since exercised his predominant powers. Various minor reforms, including a new scheme of local government and of communal taxation occupied the attention of the Prussian diet. A bill of 1891, giving compensation for the suspension of salaries of Roman Catholic clergy in Prussia during the Kulturkampf was the formal close of that long contest. A primary education bill and some anti-socialist legislation provoked controversy. The history of Prussia is now in the main but part of the history of the Empire of Germany (q.v.).

See, besides works cited at GERMANY, BERLIN, FREDERICK II., BISMARCK, &c., H. Tuttle, *History of Prussia* (Boston, 1884–88); Godefroy de Cavaignac, *Les Origines de la Prusse Contemporaine* (1890).

Prussian Blue, the name given to sesquiferrocyanide of iron, used as a colouring matter. It was discovered in 1704 by Diesbach in Berlin (whence it is also called Berlin Blue), and the manufacture was kept a secret till 1724. See BLUE; also DYEING, Vol. IV. p. 136.

Prussic Acid, a name given to Hydrocyanic Acid (q.v.) because it was first obtained from Prussian blue.

Prutenic Tables, astronomical tables compiled in the 16th century, and so called because based on the system of Copernicus, a Prussian. They were corrected by Brahé.

Pruth, a left-hand affluent of the Danube, rises in the south-east of Austrian Galicia, on the north-east side of the Carpathian mountains, and flows eastward past Kolomea and Czernowitz; from the point at which it leaves Austrian territory to its embouchure in the Danube at Reni, 13 miles below Galatz, it forms the boundary between Russian Bessarabia and Roumania. Length about 520 miles, navigable from near Jassy, 168 miles.

Prynne, WILLIAM, born in 1600 at Swainswick near Bath, from Bath grammar-school passed in 1616 to Oriel College, Oxford, and took his B.A. in 1621. He entered Lincoln's Inn, and in due time was called to the bar, but was early drawn into the vortex of ecclesiastical controversy, and during 1627–30 published *The Unlovelinesse of Love-lockes, Healthes Sicknesse* (against drinking of healths), and three other Puritan and anti-Arminian diatribes. In 1633 appeared his *Histrio-Mastix: the Players Scourge*, in whose index, on page 1104, occur the words 'Women players notorious ——.' Six weeks after its publication Henrietta Maria herself took part in a pastoral, so here was a reflection on the queen's own virtue; and on 17th February 1634 Prynne was sentenced by the Star-chamber to a fine of £5000, degradation from the bar, expulsion from Oxford and Lincoln's Inn, the loss of both ears in the pillory, and the shock to his vanity as an author of seeing his book burned in public by the hangman. He was, moreover, condemned to perpetual imprisonment, and immured in the Tower accordingly. Three years later the pertinacious offender found means to publish from his prison two more pamphlets, in which he fiercely assailed the hierarchy, and was unsparing in his personal abuse of Laud. For this he was once more prosecuted; a fresh fine of £5000 was imposed on him; he was a second time pilloried, losing such stumps of ears as the hangman before had spared; and was branded on both cheeks with *S. L.* ('seditious libeller'—rather 'stigmata Laudis' by Prynne's interpretation). He was removed successively to Lancaster, Carnarvon, and Mont Orgueil in Jersey, and remained a close prisoner till in 1640—the Long Parliament then sitting—he was released by a warrant of the House of Commons, and a tumultuous expression of popular sympathy celebrated his restoration to liberty. He acted as Laud's bitter prosecutor, leaving no stone unturned against his old enemy (1644); and in 1647 became recorder of Bath, in 1648 member for Newport in Cornwall. But opposing the Independents and Charles I.'s execution, he was one of those of whom Cromwell 'purged' the House of Commons, and was even imprisoned (1650–52) in Dunster, Taunton, and Pendennis castles. On Cromwell's death he returned to his place in parliament, bestirring himself in the royalist interest; and after the Restoration Charles II. proposed to 'keep busy Mr Prynne quiet by letting him write against the Catholics, and pore over the records of the Tower,' of which records accordingly Prynne was appointed keeper. This did keep him fairly quiet until his death, which took place at Lincoln's Inn on 24th October

1669. 'Voluminous Prynne' Wood calls him; and the continuous stream of writings on the perilous topics of the day, which was always bringing him into trouble, represents but a fraction of his literary activity. He was a great compiler of constitutional history, his most valuable works in this field being the *Calendar of Parliamentary Writs* and his *Records*, both of which contain much that is useful and important.

See vol. iii. of Howell's *State Trials; Documents relating to Prynne*, edited by S. R. Gardiner (Camden Society, 1877); and other works cited at CHARLES I. and LAUD.

Prytane'um, the town-hall of a Greek city, where the fire was kept perpetually burning, where ambassadors were received, where citizens who had deserved especially well of the state were sometimes allowed to live at the public expense; it was in fact the headquarters of the executive of the state. In Athens this body, the *prytanеis*, fifty in number, were chosen from the 500 members of the great council, five for each of the ten tribes. The five representatives of each tribe held office in rotation, one month at a time.

Przemysl, a town of Austrian Galicia, on an affluent of the Vistula, 61 miles W. of Lemberg by rail. It is the seat of a Roman Catholic and a United Greek bishop, carries on a considerable trade, and has manufactures of machinery, spirits, wooden wares, &c. Since 1874 it has been strongly fortified. Pop. 22,040, fully one-third Jews.

Psalmanazar, GEORGE, 'the Formosan,' was born probably in Languedoc, between 1679 and 1685. Educated by monks and Jesuits at Avignon and elsewhere, he at sixteen turned vagabond, and for two or three years wandered through France, Germany, and the Low Countries, by turns an 'Irish pilgrim,' a 'Japanese convert,' a waiter, a 'heathen Formosan,' and a soldier. At last at Sluys he found a ready accomplice in one Innes, chaplain to a Scottish regiment, who baptised him 'George Lauder' after the governor, brought him over to London, and introduced him to Bishop Compton. For that credulous prelate he translated the Church Catechism into the 'Formosan' language; and to him he dedicated his *Historical and Geographical Description of Formosa* (1704), which found many believers in spite of its patent absurdities, such as that Formosa belonged, not to China, but Japan, and that the hearts of 18,000 boys were sacrificed every new year. The bishop sent him for six months to Oxford, and for a while he was lionised by the highest in the land. In spite, however, of his eating raw meat and enormous quantities of pepper and opium (an opium-eater he continued to the last), people gradually lost faith in him, or the novelty wore off, or by Law's *Serious Call* (1729) he was converted to a sense of the error of his ways. Anyhow, we find him the alleged importer of a white 'Formosan' enamel, a tutor, a regimental clerk (1715–17), a fan-painter, and lastly, for years a diligent hack-writer for the publishers. The *Universal History* was largely of his compiling; and his, too, a popular *Essay on Miracles*. But in all his strange life there is nothing stranger than the esteem expressed for him by Samuel Johnson. He was the man he 'sought after most,' 'the best man he ever knew,' a man whom 'he would as soon think of contradicting as a bishop,' and whose 'piety, penitence, and virtue exceeded almost what we read of as wonderful even in the lives of the saints.' An old man of fourscore years, he died in London on 3d May 1763.

See the autobiographical *Memoirs of* * * * *, *commonly known by the name of George Psalmanazar* (1764), and articles in *Temple Bar* (1865) and the *Cornhill* (1879).

Psalmody. See HYMN, SACRED MUSIC.

Psalms, BOOK OF. This title indicates a collection of songs set to music (for use in the temple and probably sometimes in the synagogue). A more intelligible term, which like 'psalms' is of Greek origin, and is specially favoured by Philo, is 'hymns;' this corresponds exactly to the Hebrew *t'hillīm*, 'praises,' or 'songs of praise.' The eucharistic element is in fact the most essential one in the book: with the solitary exception of Ps. lxxxviii. there is an undercurrent of thanksgiving even in the most melancholy compositions (cf. Eph. v. 19, 20). There was, however, an earlier stage of psalmody, as a linguistic study of the Hebrew title assures us, when the service of religious song was of a very rough nature, and not under the control of guilds of singers. The ancient Arabs used a term (*tahlil*) which corresponds to *t'hillah* for the *shouting* of a short consecrated formula, and the common root of both names means 'to call, cry out.' Only by degrees did the Israelitish 'psalmody' rise from a shouting like that of the vintage or the bridal night to the carefully trained singing of later times. Indeed, as late as the fall of Jerusalem the noise of the Babylonian soldiers in the temple is compared to that of the worshippers on one of the olden feast-days (Lam. ii. 7).

The question therefore arises, Can our present psalms, so spiritual in tone and in form comparatively so artistic, really be the very forms of prayer and praise used by the pre-exilic Israelites? Or have they literally driven out earlier and less spiritual compositions? Or lastly, have the older formulæ been greatly expanded and idealised, or even sometimes permitted to become imbedded in later works? For this last conjecture some analogies might perhaps be found in the prophetic literature (see, e.g., Isa. ii. 2–4, and Ewald, *The Prophets*, i. 82, 83), but it can only be admitted to a hearing on proof of the existence in a psalm of really strong inconsistencies of thought and language. Till that proof is given let us accept each psalm as the monument of some particular age, without attempting to extract by analysis fragments of earlier origin than the rest of the poem. To ascertain approximately that age or those ages is the function of criticism. True; but have the critics the means of doing this? 'When once it is admitted, as it must be admitted, that the titles cannot be absolutely relied on,' says an English commentator, 'we are launched upon a sea of uncertainty' (Kirkpatrick). By no means. The question of the origin of the Psalter is of course a complicated one, but we must not say that the student of complicated problems is like a mariner without a compass. There are three conditions upon compliance with which the disagreement of critics will be reduced within very narrow limits. The first is, that no critic should approach the Psalter until he has assimilated a good number of the best critical results which have been reached in other parts of the Old Testament. The second, that he should begin at the end of the Psalter—i.e. with Books iv. and v. (the date of which, as collections, cannot, for various reasons, be later than the accession of Simon the Maccabee), and work his way backwards. The third, that he should break radically with the custom of looking at each psalm by itself, with a view to determining its period. The reason of the first is that there are numerous similarities in language and in tone between the Psalms and other old Hebrew writings; many at least of which afford valid evidence of the date of the poems, the psalmists being in a high degree imitative, and infinitely more prone, for instance, to borrow from the prophets than the prophets to borrow from them. The reason of the second is that, the Psalter being a combination of five 'books' of psalms, it is natural to presume that the two last

(which properly form but one book) are later as collections than the three first. These five books are (1) Ps. i.–xli., (2) Ps. xlii.–lxxii., (3) Ps. lxxiii.–lxxxix., (4) Ps. xc.–cvi., (5) Ps. cvii.–cl. And that of the third is that within these five 'books' there are certain minor books or psalters, which have certain common characteristics, and may, at any rate at the outset of the inquiry, be presumed to contain works of the same (not too strictly defined) period. These minor psalters are the Davidic (to which the 'Davidic' psalms in Books iv. and v. do not belong), the Korahite, the Asaphite, and the Songs of Ascent (i.e. of pilgrimage), commonly miscalled 'Songs of Degrees,' in addition to which there are various other groups of psalms, not marked by traditional headings, such as the Hallel and the Hallelujah psalms, the deutero-Isaianic (i.e. those which suggest the writer's acquaintance with the exilic portions of Isaiah), and the Jeremianic (i.e. those which from internal evidence were written either by Jeremiah or by a follower of that great prophet).

Thus, the conscious or unconscious object of recent criticism of the Psalms has been the imparting a stricter and more scientific character to the argument from internal evidence. Not the least difficult part of the work is that which relates to the linguistic phenomena, the evidential value of which has often been too much depreciated. This kind of evidence is no doubt rarely conclusive, but even in the case of the highly imitative psalm-literature will lead the critical student to some perhaps unforeseen results, unless indeed his way is barred by the arbitrary assumption that all the evidences of later date in the supposed pre-exilic psalms have been introduced by editors. And what upon the whole are the results of a criticism which does not float 'upon a sea of uncertainty?' Two very definite ones may be mentioned, with a warning, however, to the student that the criticism of the Psalter is so interwoven with that of other Old Testament books that many good Hebraists might hesitate to endorse even these moderately-stated results. First, that there is a considerable number of psalms belonging to the pre-Maccabean and Maccabean Greek portion of the post-exilic period (see especially Ps. xlix., lxxiv., lxxix., cx., cxviii., cxlix.). The possibility of this theory (which was virtually held by Theodore of Mopsuestia) is expressly admitted in the margin of our own 'Geneva Bible.' The objections to it are of various degrees of plausibility; none of them, however, are conclusive. It has been urged, for instance, that the so-called Psalms of Solomon (the composition of which falls between 63 B.C. and 46 B.C.) breathe an entirely different spirit from the psalms which may most plausibly be referred to the period of the Greek rule and of the Maccabean rising. But it can be easily shown that the latter event was a turning-point in Jewish religion, after which we might fairly expect a considerable difference in the tone even of liturgical poetry. Moreover, the phrase 'an entirely different spirit' is an exaggeration. There are certainly the germs of legalism in Psalms i., xix. 7–14, cxix., and those of later doctrines of immortality and resurrection may (if the late dates of Ps. xvi., xvii., xlix., lxxiii. be granted) be not unreasonably found in parts of the Psalter, while several of the 'Pharisæan' Psalms of Solomon contain passages strikingly parallel to our Ps. xlix. A second result is that none of the extant psalms are the genuine work of David, who was doubtless a gifted musician and poet (the early tradition on this point is clear), but whose hymns were probably too little in accordance with later ideas of art and of religion to escape the great literary as well as political catastrophe of the Exile. Contrast the life of David in the Books of Samuel with the character sketched, evidently from life, in the so-called Davidic psalms. Granting that David lived in the service of an ideal which he sought, but often failed, to realise, could that ideal have agreed with the picture presented to us in the Psalter? How much is there in the tone or the ideas or the implied circumstances of the psalms which agrees with the tone or ideas of the traditional speeches of David and with his traditional history? Enough perhaps to permit us to regard him as a far-off adumbration of the nobler members of the post-exilic church, and therefore also of Him who was the 'root and offspring of David' (Rev. xxii. 16), but scarcely more than this. Indeed the only doubt is, not so much whether any psalms are Davidic, but whether any are even pre-exilic at all. The fact (which, even without scientific proof, it would be unreasonable to doubt) that David composed some psalms was enough to make collectors call certain psalms, or collections of psalms, by his name, somewhat as the various expansions of the older law in different ages were usually referred to Moses. David was in fact the traditional founder of psalmody and to some extent (see below) a precursor of the religion of the Psalter. Perhaps, too, psalms which David really wrote may have been expanded or added to by later writers. The most plausible instance is Ps. lx.; but there is nowhere any necessity to adopt this view. It is safer to hold provisionally that certain psalms are as old as the epoch-making reign of Josiah. Yet the arguments for this view are seldom, if ever, cogent, and mainly depend for their acceptance on our ideas of historical probability, which ideas again depend on the picture we have formed, on critical grounds, of the Babylonian and Persian periods of the history of the Jews. Psalm xviii. is no doubt the psalm which would, more generally than any other, be pronounced pre-exilic. Some of the older critics were even quite sure that it was Davidic, influenced partly by the admission of the poem into what is called the appendix to Samuel (see 2 Sam. xxiii.), which, however, only proves that the poem was conjecturally ascribed to David (the idealised David of later times) by the editor of Samuel, who lived not long before the Exile. To the present writer an early pre-exilic date for this psalm seems incompatible with the internal evidence. He thinks that, though perhaps written in the reign of Josiah as a literary illustration of the life of David, it was only adopted as a temple-hymn after the return from exile, when it was doubtless interpreted as prophetic of a great future Davidic ruler or line of rulers (see Ps. xviii. 50). The final editing of the Psalter he ascribes to the temple-authorities in the time of Simon the Maccabee. The book would quickly be carried to 'Israel in Egypt,' and soon afterwards translated into Greek for the benefit of the great Jewish community at Alexandria. The date of this event cannot be fixed with precision, but it was at any rate before the Christian era.

Among the arguments for the post-exilic date of the Psalms none perhaps is more cogent than that which is based on their essential unity of tone. They have, in short, such a strong family likeness that it would be rash to spread their composition over too extensive a space. And if they all, or nearly all, belong to one period, can we be in doubt which that period is? Is it not obvious that these temple-songs were written for a community which had absorbed, in some real though still imperfect degree, the high teaching of the pre-exilic and exilic prophets? Now, though it would be absurd to say that there were no psalms before the Exile, the writings of Isaiah and Jeremiah prove that the nation, as a whole, was as yet far from having assimilated the pure and spiritual

prophetic religion, and that the priests in particular were unprogressive. How then should there have been temple-songs like those in our Psalter before that spiritual regeneration of which the 'Second Isaiah' was presumably the chief instrument? The only way to avoid the conclusion that the Psalms are (with the possible exception of Ps. xviii., and, some will add, of Ps. xx., xxi., xlv., lxi., lxiii.) post-exilic is to suppose that certain psalms, especially those which remind us of Jeremiah, were written in the reign of Josiah and during the Exile, with the prophetic hope that they would one day be required by a reorganised church-nation. This position represents perhaps the enlightened conservatism of the future, but cannot here be discussed.

In any case, the ideal character depicted in the Psalms belongs to an advanced period in Israel's history. It is that of a righteous man who, in the face of oppression, clings to his religion and his God, who trusts to be delivered, and for the most part is delivered, and who now and then forms bold anticipations of a world converted to the true God, or, it may be, crushed into reluctant obedience; and in the noblest features of this ideal it is impossible not to trace the influence of the two great prophetic teachers of the later period—Jeremiah and the 'Second Isaiah.' It is such a righteous man who, at least in Books i.–iii., for the most part appears to be the speaker, and the question arises, whether he is more accurately viewed as a personification of Israel, or as simply the typical or representative Israelite, such as every member of the congregation either was or desired to become. In some cases no one can deny that the former theory is alone correct (see, e.g., Ps. liv., lx., lxxxvii., cxvi., cxxix.), and there are not a few other psalms where its absolute rejection would involve the interpreter in the greatest psychological difficulties (see, e.g., Ps. vi., xxii., xxx., li., cxxx., cxxxi.). It has indeed been hastily stigmatised as forced and fanciful, but the number of passages elsewhere in the Old Testament which without it are unintelligible (see, besides the sections in second Isaiah relative to the 'servant of Jehovah,' Num. vi. 23–26; Micah, vii. 1, 7–10; Hosea, iv. 4, 5, vii. 8, 9; Lam. i. 3), and the numerous analogies in the Greek chornses, prove the baselessness of the charge. The solidarity of the individual and his tribe was in fact one of the ruling ideas of the ancient peoples. It is, however, *a priori* improbable that the new sense of the duties and privileges of the individual, which was stimulated (but hardly caused) by the preaching of Jeremiah and Ezekiel, should not have left its mark on the Psalter of the second temple. And do we not find such a mark on some or even many of the Psalms? Does not the personality of the psalmist sometimes at least assert itself with distinctness (see, e.g., Ps. xlv. 1, lxxiii. 2, 3, 13–17, 21–28, cvi. 4, 5, cxxxix. 18)? Yes; but it will also be noticed that even in such passages (the first and third of those just referred to are perhaps the only exceptions) the psalmist speaks, not only in his own behalf, but at any rate for a class within the Church-nation. And in some of the psalms in which a reference to the nation may most plausibly be maintained, it is almost equally possible to hold that the speaker is a typical or representative Israelite (in the sense described above), or even that the psalmist himself in the same psalm sometimes has the nation, sometimes himself, or any other pious Israelite, in view as the speaker. Reading the Psalms from this point of view makes them not less prophetic of Christ, but much more edifying and intelligible. 'The psalms,' says the eloquent Adolphe Monod, 'are filled with expressions of an unheard-of sorrow. David there speaks incessantly of his troubles, of his maladies, of his innumerable enemies; as we read them we can hardly understand what he meant.' But when we see that it is the troubles of the Church-nation, and not those of any individual, however highly placed, which are described, we can account for the strength of the language, and are also stirred up to purge our own religion of its selfishness. It only needs to be added that our conception of the life of the Church-nation must be a truly historical one. We must not rest contented with the perception that there is a strong family likeness in the Psalms. We must seek out not only resemblances but differences, and ascertain, so far as we can, the historical background of each group of psalms. Hitzig and Ewald may have gone too far in this historical 'divination,' but without exercising this faculty to some extent it is impossible fully to enjoy the Psalms. Historical data will not be wanting if we search for them, and the comparative method will here too be found applicable. The period from the Return to the Maccabees was not so monotonous as it is represented in our handbooks, and by judiciously distributing the Psalms over it on grounds of internal evidence we gain so many fresh first-class authorities for the history of the Jewish Church.

Among modern commentaries accessible in English, see J. A. Alexander (New York, 1850), Tholuck (trans. 1856), Ewald (trans. 2 vols. 1880), Delitzsch (trans. 3 vols. 1887–89), Perowne (latest ed. 1889), Cheyne (1888), De Witt (New York, 1891), Kirkpatrick (vol. i. 1891); and cf. Bishop Alexander, *The Witness of the Psalms to Christ and Christianity;* Cheyne, *The Origin and Religious Contents of the Psalms* (Bampton Lectures for 1876 and 1889 respectively).

Psaltery. See DULCIMER.

Psammetichus, or PSAMMITICHUS I. and II. See EGYPT, Vol. IV. p. 241.

Psammitic, in Geology, applied to derivative rocks composed of rounded grains, as ordinary sandstone.

Pseudepigraphy, the ascription to books of false names of authors.

Pseudomorphs, in Mineralogy, applied to minerals which assume the crystalline form of other species. Pseudomorphs result from the action upon minerals of water containing carbonic acid, oxygen, and other reagents in solution. The internal structure of a pseudomorph has no relation to the external form of the crystal. Two kinds of pseudomorphs are recognised: (*a*) *alteration* and (*b*) *substitution* pseudomorphs. Alteration pseudomorphs are the result of the chemical metamorphosis of the original mineral either by loss or gain, or exchange of constituents. Substitution pseudomorphs are minerals formed in the moulds or vacant spaces left by the total removal in solution of previously existing minerals.

Pseudonym (Gr. *pseudēs*, 'false,' and *onoma*, 'a name'), a false name adopted by an author which conceals his identity. Originally 'pseudonymous' was used of works deliberately published under a false name, so as to induce people to believe them the works of those whose names they bore, or of works erroneously attributed to a wrong person. Thus, there were pseudonymous gospels of Thomas and of Bartholomew; and the works circulated under the names of the classical writers, but proved not to be genuine, are pseudonymous works. But the term pseudonym is now most commonly used as an assumed name not really meant to mislead—what in England is often called by the French words *nom de plume* or 'pen-name,' and nearly corresponding to the French expression *nom de guerre*. There have been

periods in history when the acknowledgment of the authorship of certain pamphlets or books might mean death or banishment to the writer. It is common to find books containing attacks on public men, or those consisting of theological controversy, and the literature of satire, appearing under assumed names. In recent times young authors especially have frequently risked a new work under a pseudonym, and have kept it up afterwards. Once an author is famous it is found advisable to stick to a pen-name. For instance, every one knew the writings of 'George Eliot,' but few would at once have recognised a work by Marian Evans. The present list is not intended to be exhaustive; names in occasional use are not given, but only those which have been impressed by usage on the mind of the public. Neither have such well-known literary disguises as those adopted by the author of *Waverley* been repeated here. It may just be noted that for a longer or shorter number of years 'the author of *Waverley*,' 'the author of *John Halifax, Gentleman*' (Mrs Craik), 'the author of *Guy Livingstone*' (G. A. Lawrence), 'the author of *Grandmother's Money*' (F. W. Robinson), 'the author of *Chronicles of the Schönberg-Cotta Family*' (Mrs Charles), 'the author of *Supernatural Religion*' (unknown), 'the author of *Ecce Homo*,' '*The Autocrat of the Breakfast Table*,' &c. have been practically used as pen-names.

For further information, see the article ANONYMOUS; Weller, *Lexicon Pseudonymorum* (1886); Cushing, *Initials and Pseudonyms* (1885), and *Anonyms: A Dictionary of Revealed Authorship* (2 vols. 1890); Clegg's *Dictionary of Second-hand Booksellers, &c.* (3d ed. 1891); and Halkett and Laing's *Dictionary of Anonymous and Pseudonymous Literature* (1881–88).

Pseudopodia (Gr., 'false feet'), blunt, irregular processes of protoplasm thrown out and drawn in again by amœbæ and some other animals. See AMŒBA, PROTOPLASM, RHIZOPOD.

Pseudoscope (Gr. *pseudēs*, 'false,' and *skopeō*, 'I see'), an optical instrument through which, by means of an arrangement of prisms, objects are seen with their relief inverted. What is convex appears concave, and a figure in intaglio appears to be cut in relief. It was discovered by Wheatstone when experimenting on the Stereoscope (q.v.).

Psittacidæ. See PARROT.

Pskov, a decayed town of European Russia, 9 miles SE. of Lake Pskov (50 miles long by 13

broad), by rail 188 miles NE. of Riga and 160 SSW. of St Petersburg. Like Novgorod it was celebrated for its republican institutions after the 12th century. During the 14th and 15th centuries it was one of the Hanse towns, and had then a population three times as large as at present. In 1510 it was annexed to Moscow. During the wars with Lithuania Pskov was a stronghold of great importance. It contains a cathedral and numerous venerable churches and monasteries. Fish, obtained from the lake, and flax are the principal articles of commerce. Pop. 21,684.—The *government* has an area of 17,069 sq. m. and a pop. (1885) of 948,071; (1891) 1,029,053.

Psoralea, a genus of plants of the natural order Leguminosæ, sub-order Papilionaceæ. The flowers are blue, purple, or white. Some of the species are natives of India, others of other warm countries.—*P. esculenta*, the *Bread-root* of North America, and *Prairie Apple* of the Canadian boatmen, is a herbaceous perennial, about a foot high, with a carrot-like root, swollen above the middle, and abounding in farinaceous matter. It is used as an article of food, both boiled and raw.

Psori'asis (from the Greek word *psora*, which signifies a cutaneous eruption, supposed by some to be the itch) is now employed to signify a disease characterised by slight elevations of the surface of the skin covered with whitish scales. The eruption begins in small rounded spots, which may remain small, or may enlarge indefinitely, the centre becoming more normal while the inflamed margin continues to extend. The spots are covered by white silvery scales, not easily detached from the skin, which, however, when they are removed, is seen to be red and dry. The parts most often affected are the fronts of the knees and backs of the elbows; whatever other parts may be attacked, these are rarely free from the eruption, and the distribution is always nearly the same on the two sides of the body. Itching is often absent altogether, and very seldom severe. The disease may occur at any age, but usually first manifests itself in youth, rarely before the age of six. It is extremely apt to recur: it is rare for a person to suffer from it only once.

Numerous causes have been assigned for the disease; it has been attributed to scrofula, gout, and many other constitutional states; and doubtless it may be associated with them. But, with the exception of heredity, no cause has been satisfactorily shown to lead to its development. It frequently occurs in persons otherwise in perfect health, and, except in very severe cases, does not interfere in any way with their employments.

If left to itself, the disease generally tends to persist indefinitely. But in the great majority of cases it is very amenable to treatment, both local and constitutional. Locally, ointments containing tar, resorcin, pyrogallic acid, &c. are most in use; internally, arsenic is far the most valuable remedy. Where it has failed, iodide of potassium in large doses, liquor potassæ, and carbolic acid have sometimes succeeded. But some cases resist the most varied and persevering efforts for their cure; and nothing has yet been discovered which will prevent the tendency to recurrence of the disease.

Psyché (Gr., 'the soul'), an exquisite creation of the later mythology of Greece. She was the youngest of the three daughters of a king, and so beautiful that mortals mistook her for Aphrodite (Venus) herself, and did not dare to love, but only to worship her. This excited the jealousy of the goddess, who sent Eros (Cupid) to inspire Psyche with a passion for the most contemptible of all men; but Eros was himself wounded as deeply by her glances as ever he had wounded others with his darts. He accordingly caused her to be carried to a beautiful palace of pleasure, and here every night he visited her, unseen and unknown, and left her before morning broke. Thus Psyche might have enjoyed perpetual delight had she remembered the advice of her unknown lover, who warned her not to seek to know who he was. But her jealous sisters, whom against her lover's injunction she had allowed to visit her, played upon her curiosity, and persuaded her that she was embracing a monster in the darkness of night. Lighting a lamp when Eros was asleep, she saw with rapture that she was the mistress of the most handsome of the gods, but in her excitement she let a drop of hot oil fall on the sleeper's shoulder. This awoke Eros, who upbraided her for her mistrust, and vanished. Psyche gave way to the most passionate grief; she tried in vain to throw herself into a river, then wandered about from temple to temple, inquiring for her lover. At length she came to the palace of Venus, where she was seized by the goddess, and kept as a slave. Eros, however, who still loved her, invisibly helped and comforted the hapless maiden, reconciled her to his mother, and was finally united to her in immortal wedlock. In works of art Psyche is represented as a beautiful maiden with the wings of a butterfly. Her story was considered as an allegory of the progress of the human soul through earthly passion and misfortune to pure celestial felicity; but it must not be forgotten that it is merely a version of one of the most widespread folk-tales in the world. See CUPID, and Zingow's *Psyche und Eros* (1881).

Psychic Forces. See THEOSOPHY; and for the Psychical Research Society, see APPARITIONS.

Psychology may be briefly defined as the science of mental phenomena. After having long occupied a doubtful place as a department of metaphysics, supplemented by many empirical observations, its character as a science dealing with a special order of facts, and many of the laws of occurrence of these facts, may now be said to be established. At the same time opinion is still far from unanimous on many of the most important points of psychological doctrine, especially on such points as involve a philosophical view of the nature of mind.

The chief different ways of conceiving and defining the mental facts with which psychology has to do may be traced to the influence of rival philosophical hypotheses as to the nature of mind. Thus, in the first place, we have the view that psychology deals with the facts of the conscious mind which, when knowing, feeling, or striving, is always conscious of itself as knowing, feeling, or striving—i.e. is self-conscious. This is the view, for instance, of Sir W. Hamilton. But it has many difficulties. We can hardly ascribe self-consciousness to the lower animals or to very young children, and yet some kind of mental life clearly belongs to them: so that it would seem that mental life and self-consciousness cannot be identified. Further, many psychologists (including Hamilton) are of opinion that there are mental phenomena unaccompanied by self-consciousness even in mature human life. And if self-consciousness is thus recognised as belonging to mental life only under certain conditions and at a comparatively developed stage, it will be one of the main purposes of psychology to examine these conditions and trace its growth. In the second place, a materialistic view of mind is connected with the attempt to make brain-physiology play the part of a psychology. It is plain, however, that a sensation or a feeling of pleasure or pain is a fact of an entirely different order from a neural disturbance. The one may accompany or even cause the other (or both may

be only different aspects of the same ultimate existence), but the characteristic nature of the mental fact is not reached by the most thorough investigation of its physiological conditions, while the latter are in many cases much more obscure than the phenomena they are adduced to explain. In the third place, an attempt has been made (sometimes apart from any philosophical hypothesis as to the nature of mind) to start with certain mental facts—called presentations, sensations, or feelings—regarded as ultimate or independent, and to trace the laws and manner of their combination and succession. This method has been worked with excellent result by the English Associationist psychologists. By a similar method, and by treating presentations as forces, Herbart and his followers have elaborated a mechanism of the mind and reduced psychology to mathematical form. The difficulty of this mode of conceiving mind is to explain how a series of sensations—or any interaction of presentations—can generate the consciousness of a self persisting through changing states; and even to give any meaning to sensation or presentation without regarding it as experienced by or presented to mind. On these grounds many psychologists, while influenced by the scientific method of the Associationists and of Herbart, hold that presentation or sensation is only conceivable as belonging to a subject or mind. So far, mind must be assumed by the psychologist as implied in the experience of which he has to trace the development. This subject, or mind as the condition of experience, may be admitted to elude psychological observation. As Hume says: 'I never can catch *myself* at any time without a perception, and never can observe anything but the perception'—i.e. it is the empirical *ego*, or mind with its content of experience, which is the object of psychological observation. But the pure *ego*, or subject, is nevertheless implied by every mental fact. Psychology may, in this way, be distinguished from other sciences as dealing with subjective facts, or, rather, with the subjective aspect which belongs to all facts—i.e., as Dr J. Ward puts it, with the phenomena connected with presentation to a subject.

Method of Psychology.—If this view of the subject-matter of psychology be adopted, it is clear that the ultimate source of our knowledge of mental facts must be the knowledge each person has, through self-consciousness, of his own mental states. The mental attitude of attending to these states is called Introspection. The nature and value of introspection have been much disputed. But the arguments of Comte and others to show that the process is impossible, and psychology only another name for a department of physiology, prove too much: for were introspection impossible we should not even know that there are such things as mental states. It may be admitted, however, that the introspective attitude involves an effort of reflection which modifies the mental state we seek to observe. Consequently many obscure elements of mental life may elude its cognisance, and only become known through their effects upon the flow of ideas; while, on the other hand, states of intense mental concentration exclude it, and can only be observed introspectively in the weakened form of memory-images. It is even held by many writers that this is the sole method of introspective observation: that all introspection is retrospection. In this way the results of introspection are apt to lack accuracy, and (as each observer is limited to his own consciousness) they also lack objective or universal validity. To supply these wants the introspective or subjective method has been supplemented by objective observation both of the physiological antecedents and concomitants of mental facts, and of the expressions, products, and records of conscious life. The latter are to be found in the emotional expressions and actions of normal men; in the emotional expressions and actions of children, undeveloped races, the insane, and the lower animals; in language; and in social customs and institutions. To this side of psychological study, which involves the application of the comparative method to psychology, contributions of the greatest value have been made in the *Zeitschrift für Volkerpsychologie und Sprachwissenschaft*, edited by Lazarus and Steinthal. Further, within recent years attempts have been made to apply experimental methods to psychology. Experiments on reaction-time, for instance—i.e. on the time taken to react upon stimuli—lead to the determination of the time taken up by mental operations of different kinds and different degrees of complexity. Similar experimental methods have been adopted for investigating the accuracy of reproduction, the number of things that can be attended to at a time, &c. Laboratories, such as that at Leipzig, of which Wundt is the head, exist both in Germany and in America for the prosecution of these experimental investigations. The results of many experiments have already been recorded; but it would be premature at present to estimate the value of these results for the science of psychology. Amongst the experimenters who keep the bearing of their investigations always in view, mention should be made of Münsterberg (*Beiträge zur experimentellen Psychologie*, 1889 and following years).

Psycho-physics.—The experimental inquiries above referred to may to a large extent be traced to certain investigations (chiefly) of E. H. Weber's on *minima sensibilia* and on the relation between the intensity of the sense-stimulus (which can be measured objectively) and the intensity of the consequent sensation (which cannot be directly measured). His experiments were further carried out and their results formulated and elaborated into the science of psycho-physics by G. T. Fechner (*Elemente der Psychophysik*, 1860; reprinted 1889). By psycho-physics Fechner means the exact science of the relations between body and mind, this science being based upon facts and the mathematical relations they involve. The generalisation arrived at from experiment is by Fechner called Weber's Law, and expressed by him in the following (amongst other) terms: There will be the same sensible difference of intensity between two sensations, provided the relative intensities of the stimuli producing them remains the same. Thus, an increase of 1 to a stimulus whose strength is expressed by 100 will be experienced as of the same intensity as an increase of 2 to a stimulus whose strength is 200, or of 3 to a stimulus whose strength is 300, &c. The literature of psycho-physics is occupied with the experimental verification, the mathematical development, and the interpretation of this law. But neither its experimental basis nor its interpretation is quite satisfactory. Experiment supports it only within a certain range of sensibility. It is limited first of all by what Fechner calls the 'fact of the threshold'—i.e. the fact that a certain amount of stimulus is required to produce any sensible effect whatever; and secondly, at the other end of the scale, when the stimulus is beyond a certain intensity, the relation ceases to hold good, while within these two limits its verification cannot be said to be exact. Further, it is only in the sense of pressure and the muscular sense that we can accurately measure the intensity of the stimulus in the form in which it reaches the nervous end-organs; in hearing and sight the objective stimuli undergo physical or chemical changes in the sense-organ before reaching the extremities of the nerve-

fibres. Again, all the experimental methods for establishing the law assume the equality of least sensible differences. Thus, if there be stimuli measured respectively by 100, 101, 200, 202, causing sensations x, x', y, y', such that x' is only just distinguishable from x, y' only just distinguishable from y, it is assumed that $x' - x = y' - y$, an assumption which neglects the important fact that there is no mental content corresponding either to $(x' - x)$ or to $(y' - y)$. Finally, even if the law can be held to be established, it is not clear that it requires to be interpreted (with Fechner) as properly psycho-physical. It may also be held that the law is really physiological, the intensity of the stimulus being modified in this way by irradiation in the nerve-centres; while Wundt has attempted a psychological interpretation of it, maintaining that it holds of the relation between mere sensation and the 'apperception' of the sensation by the direction of attention to it.

Mental 'Faculties.'—The observation and description of mental facts have led to a classification of them, according to their degrees of likeness, into certain orders; and these have been frequently spoken of as different powers or functions of the mind. In the earliest stage of psychological inquiry we even have them described as different parts of the soul. In this way Plato distinguishes desire, anger, and reason, and locates them in the lower part of the body, in the heart, and in the brain respectively. But the classification which had most influence upon subsequent writers was Aristotle's. His distinction of thought and desire is the origin of the dual classification of intellectual and active powers (each with many subdivisions) which was for long almost unanimously adopted. A tripartite classification—Cognition, Feeling, and Desire or Will—was put forward by the psychologists of Kant's time, accepted by Kant, and since his time (in Great Britain since Hamilton's time) has been very generally adopted. The value of such classifications is easily, and has often been, overestimated. In the first place, it is clear that, although such functions or faculties may be distinguished, they do not operate apart from one another. No concrete state of mind consists merely of knowledge or merely of will; nor can it be properly called by one of these names, except as a means of describing it by its most prominent characteristic. In the second place, it has to be borne in mind that it is no explanation of a mental fact to refer it to a mental faculty. To maintain, as Kant, Hamilton, and Lotze did, that there are certain fundamental conscious functions or conscious elements which cannot be reduced to some single function or element, gives no real support to the view which seems to underlie much of the 'faculty-psychology'—the view that mind is a congeries of distinct faculties, and psychology a process of labelling facts and putting each into its proper compartment. To refer phenomena to memory, generalisation, &c. as their causes is to mistake a name for an explanation.

The 'Faculty-psychology' described and demolished by the English Associationists and by Herbart is, however, rather a mode of thought into which certain writers have frequently lapsed than a method which they have consciously adopted and defended. And the quest for a simple and uniform mental element from which all the wealth of conscious life has been derived is not therefore successful, because the faculty-psychology is unsuccessful. Herbart regards the interaction of presentations as accounting for all mental phenomena; in a similar way H. Spencer seeks to derive mind from a succession of somethings which can only be described as analogous to nervous shocks. But the difficulty of both is to pass from this objective element to the feeling of pleasure or pain, aptly described by Hamilton as subjectively subjective, or to the phenomena of Volition. Accordingly, many psychologists who are at one with Herbart and the Associationists in rejecting the conception of faculties as a mode of explaining facts yet hold that the final analysis we can reach of consciousness or of mental phenomena does not enable us to derive subjective feeling (of pleasure or pain) from presentation, or activity from either, the three elements being involved in the simplest state of consciousness (the term 'consciousness,' as distinguished from 'self-consciousness,' being here used as a quite general term for any mental state).

Attention.—Many of the most important controversies of psychology centre in the question of the nature and extent of the activity involved in consciousness. In its simplest form this activity is seen in the subjective reaction involved in apprehending a presentation; in its most developed form it is the act of will which determines a course of conduct upon which momentous issues are known to hang. In the latter case, as well as in the former, the critical point is the direction of Attention. Now attention is generally allowed not to be a special 'faculty,' or separate activity different from the elements of consciousness already described. It is simply consciousness regarded as active and as concentrated on some portion of its objective content, whereby the intensity of that portion is increased. The point in dispute is chiefly whether this active concentration is ultimately determined by the strength of external factors. It is clear that the direction of attention is conditioned by the previous mental groupings of ideas. Further, attention involves a muscular adjustment—at any rate when directed to objects of sense, and also (although in a less marked degree) when directed to a train of thought. These facts are differently interpreted. On the one hand, Bain, Ribot, and others find the basis of attention in the muscular adjustment; on the other hand, the muscular adjustment is looked upon as the organic expression and development of subjective activity; and this subjective activity is held to be involved in the simplest state of consciousness. The one view looks upon the external as determining and even somehow producing the internal. According to the other view the process is one in which a subjective or spiritual factor expresses itself through and gradually extends its control over an organic and physical environment.

Sensation.—Sensations are commonly defined as the simple mental states which result from nervous stimuli. This physiological reference enables us to distinguish the Special Senses, with their clearly defined organs adapted to the reception of different kinds of external stimuli, from Organic or General Sensibility, which arises from the state of the internal organs of the body (such as the alimentary canal, the lungs, and the heart), and from the Motor Sensations. These last (which play so important a part in the development of knowledge) are due to the central excitation of a motor or efferent nerve, and the consequent contraction of the muscle in which it terminates (see MUSCLE, NERVOUS SYSTEM). The sensation both modifies and is modified by the conscious state into which it enters. We have no experience, and can form no valid conception, of the mere sensation. For the subject which experiences it, it is merely an element in a complex and ever-changing whole. This is a point which has been commonly overlooked by the Associationist psychologists. They started with a succession of disconnected mental molecules, called sensations, and attempted to trace the growth of mental life from their combination. But this is to begin with an abstraction.

The earliest stage of mental life would rather seem to be a vague manifold into which distinction is just being brought; and the growth of knowledge consists not only in the addition of new elements, but in drawing new lines of distinction and forming new groupings of elements. And these distinctions and groupings may be said to be determined by the varying intensities of different elements in the changing mental content, or by the continuous redistribution of attention.

Ideation.—The mental content thus varies in the distinctness of its parts, which may even disappear from consciousness and afterwards reappear. This reinstatement in consciousness is called Representation or Ideation, and the represented or ideal contents are called Images. The circumstances determining the succession of ideas and formation of images are, first, new sense-impressions; secondly, voluntary direction of attention; and thirdly, the mutual influence of the mental elements. It is the last of these which is referred to under the title of Laws of Association. In the article ASSOCIATION OF IDEAS an account is given of the way in which one concrete experience recalls another. In every case of association a twofold process would seem to be involved. A portion of the present mental content coalesces with a resembling portion of a past mental state, and the revival of this portion involves the reinstatement in consciousness of the other elements with which it was previously connected. The latter, which is the properly reproductive process, is thus due to the fact that consciousness is not a collection of atomic sensations, but a continuous whole.

Perception is the knowledge by means of sensation of an individual object or thing. The nucleus of the percept is thus one or more present sensations which coalesce with revived or ideal elements belonging to the same sense, and combine with revived or ideal elements belonging to other senses. These presentative and representative elements are bound together and presented as a single mental content, which we refer to a portion of the body or to a thing in space beyond the body, and to which we ascribe qualities corresponding to our sensations. In brief, Perception, as distinguished from Sensation, involves, first, complexity of elements; secondly, localisation; and thirdly, individualisation and objectification. The complexity consists of the elements of present sensation, and of the ideal group with which the former coalesce or combine. The localisation clearly involves the perception of space. The individualisation and objectification may be accounted for by the following considerations: (*a*) The various sensations grouped together in a percept—e.g. the resistance, touch, colour, taste, smell of an orange—are so related that modification of one of them commonly involves modification of the others. Thus they come to be perceived as a group. (*b*) Not only are motor sensations involved in fixing attention on other sensations, but the greatest distinctness of the other sensations is commonly accompanied by conditions which admit also of sensations of touch and resistance. Hence the object comes to be experienced as offering resistance or as an *obstacle*. (*c*) In this way the other sensations come to suggest touch and resistance, and thus to be referred to a thing in space which offers resistance to our muscular energy. This forms the psychological basis of the distinction between primary and secondary qualities of matter.

The above account traces the perception of objects in so far as it is mainly dependent upon active touch—i.e. touch plus its attendant motor sensations. To active sight—i.e. sight plus its attendant motor sensations—a perception is due which differs from the preceding (*a*) in the absence of the sensation of resistance: so that we do not derive from active sight alone a knowledge of objects outside of and opposed to our own bodies, and our apparently direct perception of distance, solidity, &c. by sight is really a derived perception; (*b*) in the vastly greater number of elements simultaneously presented, so that the simultaneity of perception which characterises the developed perception of space is mainly due to visual perception.

Space and Time.—As the preceding paragraph points out, objects or things are perceived as in space. Similarly, our conscious life is apprehended as a succession—i.e. as in time. The whole of our experience may thus be said to be conditioned by Space and Time: the phenomena of external perception by space, those of internal perception by time. The two spheres are sometimes described as the object-world and the subject-world respectively. Regarding both space and time there are several questions which admit of being kept distinct. First of all, there is the question as to their reality—are they real existences, or simply modes of our subjective perception? This is a question which properly lies outside psychology, and belongs to metaphysics. Then there is the question of the way in which we form concepts of space and time. Geometry depends upon such a conception of space. The points, lines, and surfaces of geometry are not percepts, but abstractions from perception, formed as other concepts are formed. What then is that in perception from which we are able to form concepts of space and time? It must itself be a spatial or temporal percept. It is then with regard to the perceptions of space and time that the most difficult psychological question enters. And the question regarding both perceptions is affected by the secular controversy concerning the existence and the function of an *a priori* factor in mind.

Thus we start with two opposed views of the perception of space: first, the Intuitive or Nativist theory, according to which space is an innate idea (or, as since Kant it has more commonly been put, is the form in which we perceive objects), and is not derived from sensations, but is a form of perceiving, belonging *a priori* to the mind, and contributed by it in the production of experience; secondly, the Empirical theory, according to which space is the worked-up product of sensations. The universal and necessary character of the spatial perception has been brought forward in defence of the former theory. But it is important to remember that certain sensations—odours, tastes, and even sounds—are localised only indirectly, as belonging to a visible or tangible object. And this fact at once suggests the lines upon which an empirical analysis of space should be carried out. By Herbart space has been derived from a series of sensations which can be repeated in the same and in reverse order. By Bain it has been held that it is due to muscular sensation—movement giving the perception of empty space, resistance giving that of space filled or body. Sensations both of movement and resistance accompany touch; and sensations of movement accompany sight to an extent which is not nearly equalled in the other senses. In addition to this, however, we must take account of what Lotze calls the 'local signs' which belong to tactual and visual sensations. These local signs are due to the extended nature of the sense-organs of sight and touch, and are elements in sensation by which sensations arising from the stimulation of different portions of the retina (or of the skin) are distinguished from one another. The simultaneous distinctness in sensation which is due to these 'local signs' is gradually

interpreted by motor sensations, and out of these elements there gradually emerges the perception of one's own body, by relation to which other things are localised in space. Thus, although the perception of space is implied in that of body, the two perceptions grow to clearness together. Even admitting this empirical analysis, however, it may still be held—as Lotze holds—that there is an *a priori* mental tendency to form the perception of space.

The opposed views of Nativism and Empiricism are applied to the perception of time as well as to that of space. And the perception of time only seems a simpler question than the other because we are apt to confuse the succession of presentations on which it is based with a presentation of succession, which, of course, would be a presentation of time. The elements from which this presentation of time is derived may be somewhat as follows: When a number of presentations are successively presented, each grows fainter as attention passes from it, and hence arises a vague distinction between present and not-present. Afterwards, on the same series being repeated, the second member will be rising in intensity when the first is presented, and therefore in full intensity; when the second is presented, the first will be sinking in intensity, while attention will be passing on towards the third, whose intensity will therefore be rising; and so on throughout the series. Hence the vague distinction of present and not-present becomes more definite as a distinction of past, present, and future, and this is the presentation of time.

Memory and Expectation.—Both of these are distinguished from the mere succession of ideas and images by involving a reference to one's own conscious life as a succession in time. When an image is remembered its various parts have a fixed order and position, it is accompanied by a number of attendant or accessory ideas, and it is recognised as belonging to one's past self. The expected image has not always the same fixed position or number of attendant ideas; but it, too, is referred to self—one's future self, and it is characterised by an element of striving or tension and by an increasing degree of intensity. The phenomena of memory and expectation are a recognised difficulty for the theory which seeks to derive mind from the succession of presentations.

Thought.—In the process of thinking different mental contents are related together—generalised into notions or concepts, discriminated, and, in the higher forms of thought, arranged in an orderly manner under some scientific or other ideal. Thinking is further distinguished from perception and imagination by dealing with classes of things rather than particular objects, and by being mainly voluntary, whereas perception is mainly automatic. But the distinction is not an absolute one. In imagination and even in perception a process of voluntary selection may be involved, and every clear perception involves a conception of a class to which the object is referred. Further, the relating process which is characteristic of thinking may be found, though in a less explicit manner, involved in perception: for the percept has been shown to consist of a variety of elements connected together in definite ways. Carrying the analysis further, we can find no conscious content without such relations. This has been commonly brought out by emphasising the necessity of difference for consciousness. Thus, Hobbes made the assertion that 'to have always the same sensation and to have no sensation at all come to the same thing;' and this has been formulated by Bain into the Law of Relativity, that all consciousness is consciousness of difference: not, indeed (as Bain sometimes puts it), that we are conscious *only* of difference, but that all consciousness involves difference or discrimination; as it may also be shown to involve likeness or assimilation and synthesis.

Relations are thus involved in all consciousness equally with elements related. 'Feelings' and 'relations between feelings' (to use Mr Spencer's terminology) must be regarded as equally ultimate in mind. The English Associationists made consciousness begin with separate units of sensation or 'feeling;' and those writers who have received and carry on the tradition of the Associationists have devoted much attention to determining the nature of these relations. But if the ultimate datum of consciousness is not separate atoms of presentation, but what Dr Ward calls a presentation-*continuum*, and if the growth of mind consists not merely in additions to that continuum, but in drawing new lines of distinction and connection within it, we may see how neither the so-called 'feeling' nor the so-called 'relation between feelings' is independent and conceivable by itself, and how both are simply abstractions from the state of mind which—even at its simplest—is a concrete phenomenon. In other words, what is characteristic of thought as well as what is characteristic of sensation is involved in all consciousness.

Feeling and the Emotions.—The term Feeling is of very ambiguous signification in psychology. But there is a pretty general agreement to use it for the second of the three elements in the tripartite division of mind (although, unfortunately, it has not been restricted to that use). The psychology of feeling has two chief problems to deal with: first, to determine the nature and conditions of pleasure and pain, as contrasted with other elements of mental life; and secondly, to analyse into their elements, and trace the growth of, the complex feelings or emotions. The Emotions are complex states of mind in which a feeling of pleasure or pain is predominant. This feeling is connected, more or less distinctly, with a presented or ideal object, and is complicated with elements of organic sensation, and, usually, with tendencies to action or elements of desire. These complex states of feeling, or emotions, take very various forms, according to the elements of which they are composed, and their mode of origin. The classification of the emotions and the nature and origin of such emotions as sympathy and the moral sentiment are still vexed questions of psychology.

Desire and Volition.—In these phenomena we have the development of the active element in mind complicated with feeling and manifesting itself in muscular activity. Writers who regard this active element as ultimately due to the play of merely presented or external factors have attempted to derive volition from spontaneous movement (Bain) or from reflex action (H. Spencer)—factors which enter consciousness merely as motor presentations. As opposed to this we have the view that the fundamental act of will is the direction of attention to certain ideal elements or groups. Whether this direction of attention is itself determined solely by pleasure and pain is a question which has raised more controversy than perhaps any other question in psychology (see WILL). In Desire there is present the conception of an object or ideal end, accompanied by feeling and by an element of striving. Normally, when the conception of the end has been associated with definite means to its realisation, the desire is followed by a volition or act of will. The development of volition is a process of growing complexity and definiteness. Beginning with the act of attention, the power of will is gradually extended over the bodily movements controlled by muscles in connection with the motor nerves. Movements which are at

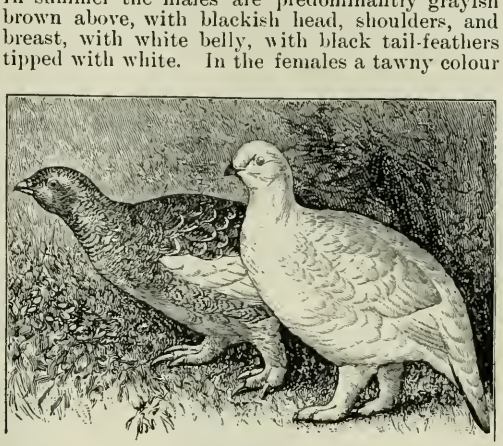
first random, reflex, instinctive, or merely expressional, are brought within its operation. Further, will grows side by side with reason and imagination, is called into operation not by sense-presentation only, but in response to images and concepts, and can thus be regulated by reason. A double tendency is at work in this development: the associative and automatic tendency of acts frequently repeated to become habitual; and the intellectual tendency by which ends and the acts tending towards them are brought into rational order. In this way the individual comes to act for permanent ends and from fixed principles, and to develop a definite character.

LITERATURE.—The first scientific treatise on psychology was Aristotle's work *De Anima*. In modern philosophy an intuitional and spiritualist theory of psychology is to be found in Descartes and Leibnitz, an empirical and materialistic theory in Hobbes. The Association-psychology, which traces descent from the psychological philosophies of Locke and Hume, and from the physiological psychology of Hartley (*Observations on Man*, 1749), may be read now in the works of James Mill (*Analysis of the Phenomena of the Human Mind*, J. S. Mill's ed. 1869), J. S. Mill (*Examination of Hamilton's Philosophy*, 5th ed. 1878), and A. Bain (*The Senses and the Intellect*, 3d ed. 1868; *The Emotions and the Will*, 3d ed. 1880; *Mental and Moral Science*, 3d ed. 1875). Belonging to the same school, but conditioned throughout by the doctrine of evolution, is H. Spencer's *Principles of Psychology* (2d ed. 1870–72). To the Herbartian influence is due the exhaustive text-book of W. Volkmann von Volkmar (*Lehrbuch der Psychologie*, 3d ed. 1884). Independent views, which are yet influenced by Herbart, are worked out by Lotze (*Medicinische Psychologie*, 1852; book iii. of *Metaphysics*, Eng. trans. 1884; *Microcosmus*, Eng. trans. 1885; *Outlines of Psychology*, Eng. trans. 1886) and by J. Ward (article 'Psychology' in *Ency. Brit.*, 9th ed.). Experimental psychology is represented by the works, among others, of Wundt, Ebbinghaus, Münsterberg, Ribot, Pierre Janet, and by many contributions to German, French, Italian, English, and American journals. A useful summary of results is given by G. T. Ladd, *Elements of Physiological Psychology* (1887). Founded largely upon these is the brilliant work of W. James, *Principles of Psychology* (1890). Important text-books are Sully's *Outlines of Psychology* (1884) and *The Human Mind* (1892), Baldwin's *Handbook of Psychology: Senses and Intellect* (2d ed. 1890) and his *Elements* (1893), Dewey's *Psychology* (1889), J. C. Murray's *Handbook of Psychology* (1885), Höffding's *Outlines of Psychology* (Eng. trans. 1891), and Maher's *Psychology* (R. Catholic, 1890). Wundt's *Lectures on Animal and Human Psychology* were translated in 1894: C. Lloyd Morgan has published *An Introduction to Comparative Psychology* (1894) and *Psychology for Teachers* (1893); and G. T. Ladd a *Primer of Psychology* (1894). See also PHILOSOPHY, and other articles cited there.

Psychrometer, an instrument for measuring the tension of aqueous vapour in the atmosphere: a wet and dry bulb Hygrometer (q.v.).

Ptah. See EGYPT, Vol. IV. p. 234.

Ptarmigan (*Lagopus*), a genus nearly allied to the true Grouse (q.v.), differing chiefly in having the toes as well as the legs thickly clothed with short feathers. Hence the name Lagopus, a name used by Pliny, from the resemblance of the foot to that of a hare. The species are natives of the northern parts of the world, of elevated or of arctic regions. With the exception of the 'Red Grouse' (*L. scoticus*), the species change colour on the approach of winter, assuming a white or nearly white plumage. All are esteemed as food. The Common Ptarmigan (*L. mutus*) occurs in a few parts of Scotland, but not in England or Ireland. It is resident in the Lofoden Islands, in Scandinavia, on the Ural and the Altai ranges, &c., and occurs on the Alps and the Pyrenees. The winter-plumage is pure white, except a black band above the eyes of the male, and some black on the under feathers of the tail. In both sexes the wings are always white, but have dark shafts to their quills. In summer the males are predominantly grayish brown above, with blackish head, shoulders, and breast, with white belly, with black tail-feathers tipped with white. In the females a tawny colour

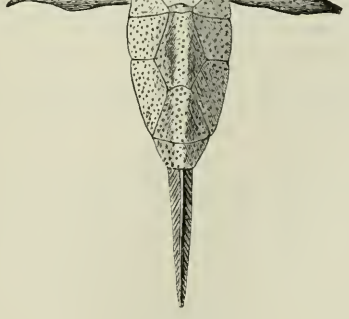


Common Ptarmigan (*Lagopus mutus*), summer and winter plumage.

predominates. In autumn, again, the plumage is different, with numerous streaks of slate-gray on the upper parts. The white winter-plumage is doubtless protective amid the snow, and may be the result of the cold; the summer-plumage is not less harmonious with the surroundings. It seems that some moulting is associated with each of the changes, but precise observations are wanting. A rough nest is scraped in the ground; the eggs (eight to ten) are laid in May, and have a buff colour. Ptarmigans are monogamous, but sometimes gregarious. They feed on tender shoots and berries. Among the related species are the following: *L. rupestris* (Siberia, Arctic America, &c.), *L. scoticus*, or Red Grouse, *L. lencurus* (Rocky Mountains), *L. hemileucurus* (Spitzbergen), and *L. albus*, or Willow-grouse (in both hemispheres). Most of the 'ptarmigan' sold in British markets are willow-grouse. See GROUSE, and Howard Saunders, *British Birds*.

Pteria. See BOGHAZ-KEUI.

Pterichthys (Gr., 'wing-fish'), a genus of extinct Ganoid fishes, remains of which occur in Devonian strata. The head and body were covered



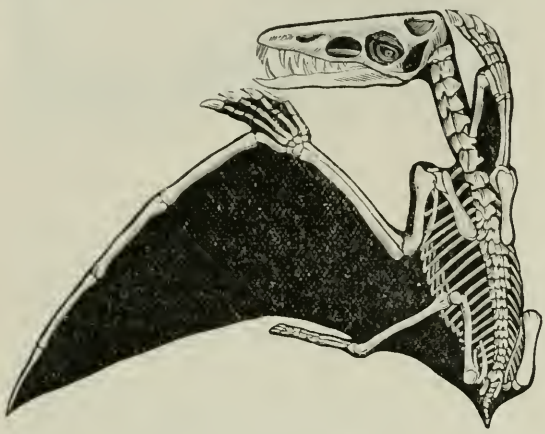
Pterichthys.

with bony sculptured plates, and the pectoral fins (to the wing-like appearance of which the name refers) were large and prominent.

Pterocles. See SAND-GROUSE.

Pterodactyl (Gr., 'wing-finger'), a remarkable winged reptile, the remains of which are met

with in the Jurassic and Cretaceous systems. There are numerous forms of Pterodactyl which are included in the extinct order Ornithosauria. The head was relatively large and snout-like, the long jaws being furnished with simple and pointed teeth, implanted in separate sockets. The eye-orbit was very large, the sclerotic having generally a ring of bony plates, and the nostrils approximated to the orbits. The neck was long and bird-like, consisting of procœlous vertebræ which were longer than the dorsals—the latter varying from seventeen to twenty in number. From three to six vertebræ are anchylosed to form the sacrum. The tail is generally short, but long-tailed forms are also met with. The scapular arch and keeled



Pterodactylus crassirostris.

sternum in their general characters resemble those of the carinate birds. There are four digits on each limb—the outer digit of the manus (corresponding to the fifth of the typical series) being immensely elongated for the support of a membranous expansion (*patagium*), which was also attached to the sides of the body to embrace the hind limbs and tail. The other digits of fore and hind limbs terminated in curved claws. Most of the bones are hollow like those of birds. The body was probably naked.

Many forms of Pterodactyl are known, in some of which the skull is less bird-like than that shown in the accompanying illustration. In Rhamphorhynchus the extremities of the jaws are usually edentulous, and were perhaps sheathed in horn; the base of the jaws, however, was furnished with teeth which were inclined forwards. In the same form the tail was long, and provided at the extremity with a leaf-like steering membrane. In Dimorphodon the jaws are provided with strong teeth in front and much shorter ones behind; and the tail was long.

Some pterodactyls were small—Ptenodraco being not larger than a sparrow. Others were about the size of a woodcock. Yet others, however, were much larger—some having a spread of wing of 5 or 6 feet, and even of 25 feet in the case of certain forms from the Cretaceous rocks of England. The form of its extremities shows that 'the Pterodactyl was capable of perching on trees, of hanging against perpendicular surfaces, and of standing firmly on the ground, when, with its wings folded, it might crawl on all fours, or hop about like a bird.'

Ornithosaurians are well represented in the Mesozoic strata of Europe and North America. One of the richest repositories of their remains is the famous lithographic stone of Solenhofen, in which the fossils usually occur in a fine state of preservation—even the impression of the membranous wing being sometimes clearly seen. See Nicholson and Lydekker's *Palæontology*.

Pteromys. See FLYING ANIMALS.

Ptero'poda (Gr., 'wing-footed'), a class or sub-class of molluscs, having two lobes of the 'foot' developed into wing-like swimming organs. They live in the open sea, and are carnivorous. Distributed in all seas, they often occur in immense shoals, and afford food to fishes and Cetaceans. The body is bilaterally symmetrical, but this is doubtless secondarily acquired. In some (Thecosomata) the viscera are covered with a delicate shell; the others (Gymnosomata) are naked, but all the larvæ have shells. The thin calcareous or gristle-like shells are abundant in the Ooze (q.v.) of some regions. It is very likely that the Pteropods should be ranked not as a separate class of molluscs, but as a sub-class of Gasteropods. Of the Thecosomata the genera Hyalea and Cymbulia are representatives, as Clio and Pneumodermon are of Gymnosomata. Fossil Pteropods appear even in the Cambrian strata. See Pelseneer, *Challenger* Report (1889). Some Pteropods are sometimes called 'sea-butterflies.'

Ptolemaic System. See PTOLEMY.

Ptolema'is. See ACRE.

Ptolemy, name of the Macedonian kings of Egypt. The first, a son of Lagos, was called *Soter* ('Saviour') by the Rhodians, whom he defended against Demetrius Poliorcetes. He became one of the greatest of the generals of Alexander the Great (q.v.), and on Alexander's death became ruler of Egypt. For the other Ptolemies, his successors, see EGYPT, Vol. IV. p. 241; and for their patronage of literature, ALEXANDRIAN SCHOOL.

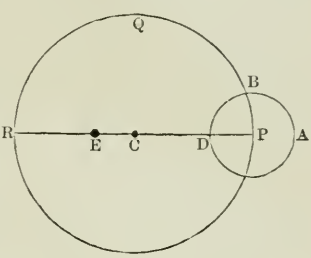
Ptolemy, properly CLAUDIUS PTOLEMÆUS, a celebrated astronomer and geographer, was a native of Egypt, though it is uncertain whether he was born at Pelusium or Ptolemais in the Thebaid. Nothing is known of his personal history, except that he flourished in Alexandria in 139 A.D., and there is probable evidence of his having been alive in 161. The chief of his writings are the Μεγάλη Σύνταξις τῆς Ἀστρονομίας, which, to distinguish it from the next mentioned, seems to have been denominated by the Greeks and by the Arabs after them *megistē*, 'the greatest,' whence was derived the name *Almagest* (with Arab article *al*, 'the'), by which it is generally known; the *Tetrabiblos Syntaxis*, with which is combined another work called *Karpos* or *Centiloquium*, from its containing a hundred aphorisms—both works treating of astrological subjects, and held by some on this account to be of doubtful genuineness; a treatise on the phenomena of the fixed stars, or a species of almanac; and the *Geographia*, his great geographical work, in eight books. The rest of his works are of inferior importance, and consist of descriptions of various kinds of Projections (q.v.), the theory of the musical scale, chronological and metaphysical treatises, and a summary of the hypotheses employed in his great work, the *Almagest*.

Ptolemy, both as an astronomer and geographer, held supreme sway over the minds of almost all the scientific men from his own time down till the 16th–17th century; but, and in astronomy specially, he seems to have been not so much an independent investigator as a corrector and improver of the work of his predecessors. In astronomy he depended almost entirely on the labours of Hipparchus. But, as his works form the only remaining

authority on ancient astronomy, the system they expound is called the *Ptolemaic System*, after the author.

As a geographer Ptolemy is the corrector and improver of the works of a predecessor, Marinus of Tyre, about whom, except from Ptolemy's writings, little is known. Ptolemy's improvements and suggestions are at once more valuable and correct; but it is sometimes difficult to separate his data from those of Marinus. His geography is divided into eight books, all of which, with the exception of the first, eighth, and a portion of the seventh, are nothing more than a catalogue of places, with their latitude and longitude (to 12ths of a degree), with a brief general description prefixed to each continent and country or tribe, and interspersed here and there with remarks of a miscellaneous character on any point of interest. The rest of the work contains details regarding his mode of noting the positions of places—by latitude (*mēkos*) and longitude (*platos*)—with the calculation of the size of the sphere of the earth, and of the extent of surface then known. The longitudes were calculated from Ferro (q.v.) in the Canaries, chosen as the westernmost part of the world; but he counted it only 2½ degrees W. of Cape St Vincent, instead of the real distance, 9° 20′. He took the parallel of Rhodes for his chief line of latitude, thinking it occupied the mean position in the zone of climate into which he divided the earth. He describes the mode adopted by him of projecting the surface of a hemisphere on a flat surface, and shows its superiority over the projections of Eratosthenes, Hipparchus, and Marinus. He also constructed a series of twenty-six maps, together with a general map of the world, in illustration of his work. See MAP.

The PTOLEMAIC SYSTEM of astronomy, so called from Ptolemy, its chief expounder, was really originated long before his time, and was, in fact, merely an attempt to reduce to a scientific form the common and primitive notions concerning the motions of the heavenly bodies. It was implicitly adopted by Plato, Aristotle, Hipparchus, and (with the exception of the Pythagoreans, and probably of Pythagoras himself) all the eminent physicists and philosophers of ancient times; passing from them to the Byzantines and Arabs, who, especially the latter, were the means of disseminating it through western Europe, where it continued to be the universally established doctrine till the 16th century. The primary and fundamental doctrines of this system are that the earth is the centre of the universe, and that the heavenly bodies revolve round it in circles, and at a uniform rate. These notions, which are naturally suggested by the first general aspect of things, having, previous to any accurate observation, established themselves as unquestionable axioms, phenomena which were found on closer examination to be inconsistent with them were explained by the introduction of additional hypotheses. The belief that the earth is the centre of the universe was supported by its accordance with the relation of the primary elements of which the material world was supposed to be composed. Thus, earth, the most stable of the elements, held the lowest place, and supported water, the second in order; above water was placed air, and then fire, ether being supposed to extend indefinitely above the others. In or beyond the ether element were certain zones or heavens, each heaven containing an immense crystalline spherical shell, the smallest enclosing the earth and its superincumbent elements, and the larger spheres enclosing the smaller. To each of these spheres was attached a heavenly body, which, by the revolution of the crystalline, was made to move round the earth. The first or innermost sphere was that of the moon, and after it in order came those of Mercury, Venus, the Sun, Mars, Jupiter, Saturn and the fixed stars, *eight* in all. To this system later astronomers added a *ninth* sphere, the motion of which should produce the Precession of the Equinoxes (q.v.), and a *tenth* to cause the alternation of day and night. This tenth sphere, or *primum mobile*, was supposed to revolve from east to west in twenty-four hours, and to carry the others along with it in its motion; but the Ptolemaic astronomers do not venture to explain how this was done, although, since the axis of motion of the *primum mobile* was that of the equator, its extremities being the poles of the heavens, while that of the ninth sphere was the axis of the ecliptic, some explanation was certainly necessary. As observations of the heavens increased in accuracy it was found that the heavenly motions were apparently not uniform, and this was explained as follows: The acceleration of the sun on one side, and retardation on the other side of his orbit is only apparent, and results from the earth not being in the centre of the sun's sphere, C (see fig.), but at E, and consequently his motion appears to be slowest at P and quickest at R. The alternate progression and regression of the planets was accounted for by supposing them to move, not directly with their crystalline, but in a small circle, whose centre was a fixed point in the crystalline, and which revolved on its axis as it was carried round with the latter; thus (fig.) the planet was carried round the small circle ABD, as that circle was carried round PQR (now supposed to represent the planetary crystalline). The planet while in the outer portion of its small circle would thus have a forward, and in the inner portion a backward motion. The larger circle was called an *eccentric*, and the smaller an *epicycle*. This theory of eccentrics and epicycles satisfied the early astronomers; but further investigation showed its incompleteness, and in later times it was found necessary to explain newly-discovered discrepancies by heaping epicycle upon epicycle till a most complex entanglement resulted. As soon as astronomers came to understand and test the Copernican Theory (see COPERNICUS), this venerable and disorderly pile of hypotheses, which had received the papal seal of infallibility, and had in various forms held supreme sway over the minds of men for twenty centuries, at once crumbled to atoms and sunk into oblivion. See ASTRONOMY.



The *Almagest* and the *Geography* were the standard text-books to succeeding ages, the first till the time of Copernicus, the second till the great maritime discoveries of the 15th century showed its deficiencies. They have passed through numerous editions, the best of which are, for the *Almagest* and the most of Ptolemy's minor works, that by Halma (Paris, 4 vols. 1813–28); and for the *Geography*, the Latin versions of 1482 and 1490, published at Rome, the *editio princeps* of the Greek text by Erasmus (1533), the Elzevir edition (1619), those of Wilberg and Grashof (1844), Nobbe (1845), Müller (Paris, 1883), and the photographic reproduction of the MS. in the monastery of Mount Athos by Langlois (Paris, 1866). The catalogue of stars has been frequently reprinted separately, the best edition being that of Francis Baily, in vol. xiii. of the *Memoirs of the Royal Astronomical Society* (1843).

Ptomaines. It has been known for a very long time that food which has undergone putre-

faction may, under certain circumstances, act as a violent poison, setting up severe catarrh, and producing symptoms of a more general nature. Stale mussels, fish, and sausages have even a popular reputation on account of their poisonous qualities. A ptomaine was first obtained by Marquardt in 1865, and described by him as similar to coniine; in 1869 Sülzer and Sonnenschein isolated a crystallisable ptomaine which resembled in its qualities atropine and hyoscyamine. Of recent years attention has been called to this question from another point of view, and one of special interest to the medical jurist. At a trial at Rome, on the occasion of a supposed murder, a material was extracted from the body which had markedly poisonous qualities, similar to those of delphinine. It was supposed by those who undertook the prosecution that this poison had been administered to the deceased, but on the side of the defence it was pointed out that the extract, though similar in some respects to delphinine, was in others quite distinct, producing on the frog's heart very different effects.

Attention having been called to the subject, scientific investigators, especially those of Italy and Germany, busied themselves in extracting these poisonous materials, ptomaines (Gr. *ptōma*, 'a corpse'), from putrescent animal matters, and investigating both their chemical and physiological properties. These ptomaines can hardly be said to form a very distinct group of bodies from a chemical point of view, for some, like putrescine and cadaverine, are amines; others are amido-acids, like creatinin; and neurine, which has choline and muscarine closely allied to it, is trimethyl-vinyl-ammonium-hydroxide. It is even questionable whether they may be said to possess an alkaline reaction, at one time supposed to be a common property of all ptomaines, and one which related them to the vegetable alkaloids, for Salkowski has recently shown that creatinin, a body that has been long known and apparently carefully investigated, when obtained pure gives no reaction with litmus-paper, nor does it possess the power of combining with acids like a base. Brieger, too, has pointed out that it is scarcely possible to look upon ptomaines as powerful reducing agents, since many of them, especially those rich in oxygen, are deficient in this power.

Neither from a physiological point of view can we look upon the ptomaines as *sui generis*, and in the first case because many of them are produced by the action of organisms *during their life*. As well-known examples let us instance creatinin and neurine, which are produced every day in our living bodies, showing that during the putrefactive process we cannot be said to find substances which stand alone, and are invariably different from those formed during digestion and assimilation. Finally, in respect to their poisonous properties, not only are some of them perfectly harmless or poisonous only in a minor degree, but it is highly probable that some of the most poisonous products of the action of putrefactive and other organisms are bodies (albumoses) of quite a different chemical constitution. It is therefore probable that in a few years, when more positive information is at our command, the term ptomaine will either be dropped altogether or restricted in its usage. In the meantime scientific men are actively investigating these bodies, and throwing much light on several involved problems of chemical physiology and preventive medicine.

See Selmi, *Sulle Ptomaine ed Alkaloidi Cadaverici* (Bologna, 1878); Panum, 'Das putride Gift, die Bacterien' (Virchow's *Arch.*, Bd. 60, § 301); Nencki, 'Zur Geschichte der basischen Fäulnissproducte' (*Journ. f. pract. Chemie*, Bd. 26); Brieger, *Ueber Ptomaine* (Berlin, 1885); also the article PYÆMIA.

Ptosis (from the Gr. *piptō*, 'I fall') signifies a drooping or falling of the upper eyelid, and arises from weakness of the muscle which elevates it, or from palsy of the third or *motor oculi* nerve. If it is congenital, or occurs without any apparent cause, and resists medical treatment, it may be removed by a surgical operation, by which the eyelid is brought under the action of the occipito-frontal muscle, which receives its nervous power from another source.

Ptyalin, PTYALISM. See SALIVA.

Puberty is the period of life at which the reproductive organs in both sexes begin to be functionally active, and is marked by other important changes in the structure and functions of the body. Among the peoples of northern Europe it begins in girls at from twelve to fourteen, and in boys about two years later. In girls both growth and development are about this period much more rapid than in boys; the breasts enlarge, and the figure becomes full; the temperament changes; and the menstrual flow begins to appear. In boys the most obvious changes are the breaking of the voice and the growth of hair on the face. The changes begun at this time are not fully completed nor the bodily and mental vigour of adult life established for at least eight or ten years after the commencement of puberty. The health during this period is specially liable to be disturbed by adverse influences, particularly in the female sex; and overstrain, both of the physical and mental powers, should be carefully guarded against.

Publicani (from Lat. *publicum*, 'that which is public or belongs to the state'), the name given by the Romans to those persons who farmed the public revenues (*vectigalia*). These revenues were put up to auction by the censors, and were 'sold' for a period of five years. They were derived chiefly from tolls, tithes, harbour-duties, the tax paid for the use of public pasture-lands, mining and salt duties; and from the special taxes they collected, publicani were classified as *decumani*, *pecuarii* or *scriptuarii*, and *conductores portoriorum*. As the state required them to give security for the sum at which they had purchased the collecting of the taxes, and as this sum was usually much greater than the wealth of any single individual, companies (*societates*) were formed, the members of which took each so many shares and were thus enabled to carry on conjointly undertakings far beyond the capabilities of the separate shareholders. Every *societas* had also a head-manager (*magister*), who resided at Rome, and transacted all foreign correspondence with the inferior officers who directly superintended the collection of the taxes. The publicani belonged to the order of *equites*, and formed from their immense profits a powerful capitalist class. Under the empire the land-tax and poll-tax came to be collected by officers of state—in senatorial provinces, the quaestor; in imperial provinces, an imperial procurator assistant to the governor; while in provinces like Judæa, administered by an eques, the governor was himself at the same time procurator. The customs, on the other hand, even in the days of the empire, were still commonly leased out to publicani, and so undoubtedly in Judæa. No doubt territorial princes like Herod Antipas also employed this method of collecting their taxes.

The lessees again had their subordinate officials, who would usually be chosen from the native population. But even the principal lessees in later times were not necessarily Romans. Zacchæus, the tax-gatherer of Jericho (Luke, xix. 1, 2), was a Jew. The tariffs were often very indefinite, opening a door to arbitrariness and rapacity. Hence in New Testament phraseology the terms *publicans* and

sinners are synonymous, while in the rabbinical literature tax-gatherers appear in a still less favourable light.

Puccinotti, FRANCESCO, author of the *Storia della Medicina* and of other works which give him a high place in medical literature, was born at Urbino in 1794, and, thanks to the Scolopian Fathers, was already an accomplished classical scholar when in 1811 he repaired to Pavia for a thorough course of mathematics, physics, and natural science, in which metaphysics, ethics, and civil history were not neglected. From these studies he passed on to that of medicine at the Roman University, and graduated with much distinction in 1816. The local malaria first engaged his attention. A work ardently opposing the prevalent Brunonian doctrine, and advocating a return to the rational medicine of Hippocrates, produced a salutary effect on his contemporaries, and was followed up by his able treatises on Pernicious Fever (1821) and on Inductive Pathology (1828). Academic honours now fell thick on him, and he passed from one medical chair to another, till, compromised in the patriotic movement of 1831, he was deposed from the professorship of Pathology in the university of Macerata. Excluded from academic, he redoubled his literary activity, which bore fruit in his still classic treatises on medical jurisprudence and on nervous maladies. In 1835–37 he made a special study of the cholera epidemic at Leghorn, at the same time giving to the world his masterly translation of Aretæus. In 1838 the Tuscan Archduke appointed him professor of Medical Jurisprudence in Pisa University, and there he published his *Lezioni Speziali sui Mali Nervosi*, his work on the *Cachexiæ*, and on the maladies induced by the rice-culture (*Risaie*), and, above all, his masterpiece, the *Storia della Medicina*, in three volumes, representing the labour of twenty years. He died, 8th October 1872, in Florence, and, by special decree of the municipality, was buried in the 'Westminster Abbey of Tuscany,' the church of Santa Croce.

Puck, or ROBIN GOODFELLOW, a familiar figure in the fairy-world of old English folklore, immortalised by Shakespeare in the *Midsummer Night's Dream*. His characterisation here keeps close to popular tradition in the merry tricks and mischievousness attributed to him. The name is really a generic term for a fairy, and we recognise it further in the Icelandic *puki*, the Irish *pooca*, the Welsh *pwcca*, even the Cornish *pixie*, and the Puk and Niss Puk of the Frisians and Danes. The Pucks occasionally perform kindly domestic functions, are small and dwarf-like in appearance, attach themselves to particular households, and are easily propitiated by offerings of cream and kindly names like the Irish 'good people,' the Scotch 'good neighbours.' They may assume the form of a horse, a hound, or the like, and are even confounded with such dancing lights as the Will-o'-the-Wisp or Jack o' Lanthorn. Obvious analogies suggest themselves with the Silesian Rubezahl, the Scotch Brownie, the Norse Troll, whose more malignant aspects connect them with the wider world of Demonology (q.v.). Robin Goodfellow once filled a prominent place in the popular imagination—we meet him at full length in the 1628 black-letter tract, *Robin Goodfellow: his mad pranks, and merry Jestes, full of honest mirth, and is a fit medicine for melancholy* (repr. in Halliwell). Henslowe's Diary tells us that Chettle wrote a drama on his adventures; we find him again in Drayton's *Nymphidia*, Burton's *Anatomy of Melancholy*, Ben Jonson's *Masque of Love Restored*. As Lob, Hobgoblin, and the Lubber-fiend also the allusions to him in our earlier literature are endless.—The name *Puck* was taken for its title by the well-known New York counterpart to *Punch*.

See J. O. Halliwell's *Illustrations of the Fairy Mythology of A Midsummer Night's Dream* (Shakesp. Soc. 1845); W. J. Thoms's *Three Notelets on Shakespeare* (1865); and W. C. Hazlitt's *Fairy Tales, &c., illustrating Shakespeare and other English Writers* (1875).

Pud, or POOD, a Russian weight which contains 36 lb. avoirdupois (40 lb. Russian).

Pudding-stone. See CONGLOMERATE.

Pudukota. See INDIA, p. 110.

Puebla, the third city of Mexico, capital of a state of the same name, stands on a fruitful plain, 7120 feet above sea-level, and 68 miles (by rail 116) SE. of the city of Mexico. In the vicinity are Orizaba, Popocatepetl, and other lofty mountains. It was founded in 1531, and is one of the handsomest towns in the republic, with broad, straight, clean streets; many of the houses, which are generally three stories high, have quaint fronts of red and white tile-work. The city contains nearly fifty churches, theological, medical, art, and normal schools, a museum of antiquities which dates from 1728, two large libraries, a number of hospitals, &c. On the great square stands the cathedral, a Doric building with two towers, the interior of which is decorated in the most sumptuous manner with ornaments of gold and silver, paintings, statues, &c. Puebla has a thriving trade, and an air of cheerful activity, not common in Mexico, pervades the place. In 1889 there were twenty-two factories; the chief articles produced are cottons, paper, iron, glass, porcelain, leather. Pop. (1895) 91,917. Puebla was besieged for two months by the French, and then taken by storm, 17th May 1863.

Pueblo, capital of Pueblo county, Colorado, on the Arkansas River, at the mouth of Fountain Creek, 117 miles by rail S. by E. of Denver. Through its iron and steel industry it has rapidly become the second city of the state and an important railway centre; immense quantities of raw materials and fuel abound in the vicinity. The principal establishments are those of the Colorado Coal and Iron Company, which include two blast-furnaces, steel-works, a rail-factory, bar- and nail-mills, and a pipe-foundry. In 1890 a Mineral Palace was erected to hold a permanent exhibit of Colorado's mineral productions—from stone and coal to pure gold—valued at almost $1,000,000. Pop. (1880) 3217; (1890) 24,558.

Pueblos (Span. *pueblo*, 'village'), a semi-civilised family of American Indians in New Mexico and Arizona, dwelling in large single habitations, which are sometimes capacious enough to contain a whole tribe. These edifices—which are often five or six stories high, and from 130 to 433 yards long, with many rooms (53 to 124) on each floor—are commonly constructed of adobe or sun-dried brick; the ground-floor is invariably without doors or windows, entrance being effected by a ladder leading to the second story; and

indoors ladders take the place of staircases everywhere. A somewhat pyramidal aspect is given to the whole building by each successive story receding a few feet from the line of that below it. Each family of the tribe has a separate apartment, and there are also large rooms for general council-chambers and for tribal dances. In New Mexico there are nineteen such villages, with over 8000 occupants, who are skilful agriculturists, employing irrigation ditches extensively, and rear horses, cattle, and sheep. Spinning and weaving and the manufacture of pottery also are carried on. The Moquis of Arizona are a related tribe, numbering some 1800, in seven villages built on the summit of isolated hills. The Pueblos are under Roman Catholic missionaries, and are making steady progress in civilisation and education, although on their Christianity they have grafted many of their old pagan beliefs and customs, to which they obstinately cling. They were first visited by the Spaniards about 1530, at which period their habits and their habitations were very much the same as to-day. It is evident, however, from the wide area over which the ruins of old pueblos and remains of ancient pottery have been found, that they were at one time very much more numerous than they are now.

Puente Nacional, a town of Colombia, in Santander department, on the Rio Suarez. Coal and iron are mined, and there are some trifling manufactures. Pop. 12,000.

Puerperal Fever. In its most general sense this term may be applied to any acute febrile disease affecting women during the puerperal or lying-in state. In this sense it might be taken to include the febrile states induced by the poisons of scarlatina, typhus, and other zymotics. But, while the zymotic poisons induce manifestations in the puerperal woman in some respects widely differing from the results of their action in the non-puerperal state, their features are quite distinct and recognisable, and the special characteristics of their action depend on the peculiar condition of the subject for the time being, and not on any difference in the specific character of the poisons. The term puerperal fever is now in its narrower sense restricted to that special acute febrile disease resulting from the septic infection of the puerperal woman, and may be considered to be synonymous with the term puerperal septicæmia.

It is a frequent and much dreaded disorder, and accounts for a very large number of the deaths arising from child-bearing. Its dread character and symptoms were recognised by Hippocrates and by him regarded as due to the suppression of the lochia or discharge after childbirth—a view which held ground for nearly 2000 years—for in 1680 Sydenham taught practically the same opinion. From this time until 1847 various views as to its cause and nature prevailed. But in this year the true nature of the cause was recognised by Semmelweiss of Vienna, who noticed that in a clinic in the maternity which he conducted, and which was attended solely by midwives, puerperal fever scarcely ever occurred, while in another attended by students, many of whom came straight from the dissecting-room, its ravages were appalling. From this he argued, after careful analysis of his observations, that the students brought into the maternity a poison that induced in the women they attended and examined the disease, which was conspicuous by its absence in the ward attended by the midwives only. Abundant evidence has accumulated since to show that his views were correct, and it has been shown that of all the causes of this malady the poison termed cadaveric (i.e. derived from the decomposing dead body) is one of the most active and fatal. Modern research has shown us that the activity of this and other septic poisons is due to the influence of microbic organisms or 'germs,' and we are well aware that a great variety of such germ-bearing substances exist, each capable of inducing the symptoms and condition which we recognise under the name of puerperal septicæmia. Thus, while the results are to all intents the same, the causes may vary considerably in their ultimate nature, and may be derived from a variety of sources; for example, the cadaveric poison already referred to, the pus from a septic abscess, sewage gas, &c. It would seem that the septic poison may be introduced into the system in two different ways, and this distinction has an important clinical and practical bearing. (1) The so-called Heterogenetic mode includes those cases in which the poison is applied to the tissues of the patient directly, as from the hands of the accoucheur. The microbe then enters the tissues and produces its effects by developing in and influencing the vitality of the tissues themselves. (2) The so-called Autogenetic mode. In this case a piece of the retained placenta, blood-clot, or slough remains in the genital tract. Putrefactive changes set in as the result of microbic infection, and the products of the putrefaction enter the system and exert their morbid influences upon it. In this class of cases the patient as it were manufactures the immediate poison in her own body (hence the term). But it will be evident that in both the ultimate cause is the presence of microbic organisms. The symptoms may occur in from two to fourteen days after labour. They begin with a rigor or 'chill,' followed by a rapid rise of pulse and temperature. Thereafter pain in the abdomen usually sets in and the lochia become fetid or suppressed. The local manifestation of the disease consisting of inflammatory changes varies in kind, degree, and site. Almost all the organs may be involved, more especially the uterus, peritoneum, kidney, liver, &c. In some cases the influence of the poison is so overpowering and rapid that death ensues before any gross change in the tissues occurs, but usually there is abundant evidence of the extent of the anatomical changes.

Once the disease is fairly established the prognosis is grave in a high degree. The chances of recovery where the treatment is appropriate and vigorous are very much greater in the autogenetic variety than in the other. The seat of the mischief can be attacked, and the decomposing matter either entirely removed, or the putrefactive process stopped by the use of efficient antiseptics. Where the sepsis has been introduced directly (heterogenetic form) the possibility of direct interference is almost *nil*, and the matter resolves itself into a contest between the vitality of the victim and the activity of the poison, in which the former often succumbs.

The preventive treatment (*prophylaxis*) of this scourge is, however, one of the triumphs of modern medicine. Up to 1870 the special home of puerperal septicæmia was the lying-in hospital, where the atmosphere and furniture were saturated with the septic material derived from the emanations and excreta of previous patients. Such institutions were seldom long free from outbreaks of this scourge, and from time to time epidemics arose with a virulence and effect that made the total mortality appalling. But from 1870 and onwards the increasing knowledge of the influence of germ poison in disease-production and the power of antiseptics in keeping this influence in check began to tell, with the result that such outbreaks are now entirely unknown and the mortality is practically reduced to *nil*. No better illustration of this advance can be found than the experience in the Royal Maternity Hospital of Edinburgh. In 1879 the new

hospital was opened, and though it was constructed on the most advanced sanitary ideas several fatal cases occurred during the first three or four months after its opening. The source of the mischief was never discovered; but a vigorous antiseptic and aseptic course was instituted in the management of the practice, and since then no single case of septicæmia has occurred.

A similar result has been attained in the great maternity hospitals on the Continent, and indeed it is found everywhere that the more rigorous the antiseptic practice the more nearly perfect is the immunity from the disease. In no department of practical medicine have the discoveries and teaching of Lister produced more brilliant results. For while it might well have been said that until recently a woman in entering a maternity hospital took her life in her hands, it now appears that since antiseptics in midwifery have been rigorously adopted a woman is actually safer in such an institution than in her own home. For while careful antiseptic practice is practically a routine in the hospital, it is apt to be faulty in a private house by reason of some constructional fault in the dwelling or ignorance or carelessness on the part of the attendants. And thus, while septicæmia is practically stamped out of hospital practice, it is still far too common in private.

The chief points attended to in hospital practice are (1) the thorough cleanliness of the bedding and clothes of the patient—all soiled articles being at once removed and disinfected before being washed. (2) The scrupulous cleansing of the wards and delivery rooms from time to time. (3) The extreme personal cleanliness of all attendants—accoucheur and nurses—the hands being carefully disinfected on every occasion before a patient is touched. (4) The rigid exclusion from the clinics of all who are in attendance on infectious or septic cases or in the post-mortem or dissecting rooms. (5) The prevention of septic absorption by the free use of antiseptic lotions and dressings. While such practice can, with due care, be constantly maintained in hospital, it is obvious that the conditions of private practice render its application more difficult; and while antiseptics have rendered the disease immensely less frequent, it is doubtful if we can hope for the almost complete immunity in private which we have attained in hospital practice.

Puerperal Insanity comprehends the forms of mental derangement which may attack a woman during pregnancy, parturition, and the puerperal period. The occurrence of insanity during pregnancy is extremely rare; it is much more frequent during the early puerperium, and is liable to occur, but with less frequency, during the whole period of lactation. The affection presents many varieties, such as acute mania (which is probably the commonest), delusional mania, melancholia, &c. As regards frequency, it would seem that about 8 per cent. of all cases of insanity have a puerperal origin. This is derived from a very large number of cases, and the proportion in different places varies greatly. A very large proportion of the cases show a hereditary tendency to insanity, but it occurs to a great extent among those in whom no such taint can be recognised. Primiparæ are more frequently the victims than those who have borne several children; and there seems no doubt but that it is more apt to appear in those whose physical state has become depressed from one cause or other.

Illegitimacy seems to exert a potent influence in the production of this disorder. This comes out in Clouston's statistics. He says that 25 per cent. of all insane puerperal women are unmarried. This apparent close relation may be somewhat misleading, because while these unfortunates are no doubt the subjects of great mental distress, and often of physical hardships leading to lowered vitality—conditions which certainly favour the development of this disorder—yet it must be borne in mind that this is the very class who most frequently seek the shelter of lying-in hospitals, from whose wards the statistics are chiefly derived. It may generally be said that a depraved state of the nutritive system precedes attacks of insanity, and whatever tends to induce this favours the development of an insane attack. About 70 per cent. of those attacked become acutely maniacal. There is great excitement, incoherence, and often great and dangerous violence. There is continuous garrulity, and the language is frequently markedly profane or obscene. Violent explosions occur from time to time, often characterised by homicidal and suicidal tendency.

The melancholic form is characterised by an attitude and expression of great mental depression, speech is slow, and replies can only be elicited with difficulty. The eyes are lustreless and downcast, and the whole bearing suggests profound dejection. Suicidal attempts are not uncommon in the melancholic forms, and must always be guarded against. The symptoms usually appear within the first seven days after labour, and may develop with great rapidity. In both the melancholic and maniacal forms there is an aversion to food, the tongue becomes coated, and the secretory and excretory functions are greatly disordered. Sleeplessness is very pronounced, and hysterical outbursts, delusions, and hallucinations occur, and mania or melancholia rapidly supervenes. It is satisfactory to know that in spite of the violence of this disorder the chances of ultimate recovery are very great. Upwards of 80 per cent. recover entirely. Most of the maniacal cases get well within eight weeks, the melancholic within six months. In a small proportion of the cases recovery is deferred until nine months, after which the chances of complete recovery are considerably diminished. In this connection it should be noted that the rapidity of recovery depends on appropriate treatment being early begun. Experience shows that the majority of cases in which treatment is early begun get rapidly well, and that the chances of recovery are diminished in proportion as the treatment is deferred. Repugnant then as may be the removal of the patient to an asylum, there can be no doubt that, in the great majority of cases, this is the proper course to adopt. When one recalls the fact that most of the cases have a suicidal or homicidal tendency which it is often difficult to guard against in a private house, and at the same time understands that early recovery depends on early treatment, the propriety of the patient's early removal scarcely admits of question.

See Clouston, *Mental Diseases;* Bevan Lewis, *Textbook of Mental Diseases;* Lloyd, 'On Insanity and Diseases of the Nervous System in the Child-bearing Woman' (*American System of Obstetrics*, vol. ii.).

Puerto Bello. See PORTOBELO.

Puerto Cabello, a seaport of Venezuela, in Carabobo state, 78 miles W. from Carácas. It stands on a long, low, narrow peninsula on the Caribbean Sea, and has a safe, deep, and roomy harbour, defended by a fort and batteries. It is the port of Valencia, which is 34 miles distant by rail. There is an active foreign trade, which averages 1¼ million sterling annually; the chief exports are coffee, cacao, indigo, cinchona, cotton, sugar, divi-divi, and copper ore. Pop. 10,145.

Puerto Cortez, a port of Honduras (q.v.).

Puerto de Santa Maria, a seaport of Spain, stands at the mouth of the Guadalete, on the Bay of Cadiz, 22 miles by rail (all round the bay) NE. of Cadiz and 8 SW. of Xeres. It is one of the

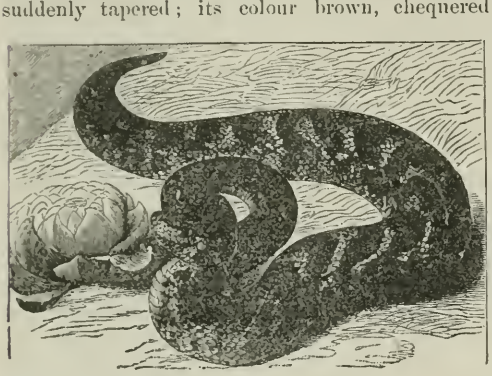
principal export harbours for sherry, and manufactures silk, soap, hats, leather, spirits, beer, &c. The bull-fights here in May are among the most famous in the country. Pop. 22,125.

Puerto Plata, the chief port of the Dominican Republic, on the north coast of the island of Hayti. It has an open roadstead, but exports a good deal of tobacco, mahogany, sugar, coffee, cocoa, divi-divi, &c. The value of imports and exports varies from £230,000 to £300,000 a year. Pop. 6000.

Puerto Principé, an important inland town in the east of the island of Cuba, 40 miles SW. of its port, Nuevitas, with which it is connected by railway. It manufactures cigars and carries on a busy trade. Pop. 46,641.

Puerto Rico. See PORTO RICO.

Puff-adder (*Clotho* or *Echidna arietans*), one of the most venomous and dangerous vipers of South Africa. Its popular name refers to its habit of puffing itself up when irritated. It attains a length of 4 or almost 5 feet, and is often as thick as a man's arm. Its head is very broad; its tail suddenly tapered; its colour brown, chequered



Puff-adder (*Clotho arietans*).

with dark brown and gray or white. The puff-adder is very sluggish, and often lies half buried in the sand of the desert, its head alone being raised above ground. Its poison is used by the Bushmen for their arrows. The River-jack (*Clotho nasicornis*) is also South African; the male bears a scaly spine between the nostrils.

Puffball (*Lycoperdon*), a Linnean genus of Fungi, now divided into many genera, belonging to the section Gasteromycetes. They mostly grow on the ground, and are roundish, generally without a stem, at first firm and fleshy, but afterwards powdery within; the powder consisting of the spores, among which are many fine filaments, loosely filling the interior of the *peridium*, or external membrane. The peridium finally bursts at the top, to allow the escape of the spores, which issue from it as very fine dust. Some of the species are common everywhere. Most of them affect rather dry soils, and some are found only in heaths and sandy soils. The most common British species is *L. gemmatum*, generally from one to two and a half inches in diameter, with a warty and mealy surface. The largest British species, the Giant Puffball (*L. giganteum*), is often many feet in circumference, and filled with a loathsome pulpy mass when young; but in its mature state its contents are so dry and spongy that they have often been used for stanching wounds. Their fumes, when burned, have not only the power of stupefying bees, for which they are sometimes used, in order to the removal of the honey, but have been used as an anæsthetic instead of chloroform. The same properties belong also to other species. Some of them, in a young state, are used in some countries as food, and none of them is known to be poisonous.

Puff-birds (*Bucconidæ*), a family resembling Kingfishers in form, but living on insects like Fly-catchers; they also resemble the Bee-eaters, and are found only in South and Central America. See BARBET, and Sclater's *Monograph of the Jacamars and Puff-birds* (1882).

Puffendorf. SAMUEL, BARON VON PUFFENDORF (or Pufendorf), writer on jurisprudence, was born on 8th January 1632, at Chemnitz, in Saxony. He began the study of theology at Leipzig, but in 1656 went to Jena to study national law and mathematics. Whilst acting as tutor to the sons of the Swedish ambassador at Copenhagen war broke out (1658) between Denmark and Sweden, and Puffendorf was thrown into prison. During the eight months he was kept there he thought out his *Elementa Jurisprudentiæ Universalis*. It was dedicated to the Elector Palatine, who appointed Puffendorf to the professorship of the Law of Nature and Nations at Heidelberg. He next exposed the absurdities of the constitution of the Germanic empire in *De Statu Reipublicæ Germanicæ* (1667), which raised a storm of controversy. In 1670 he was called to fill the chair of the Law of Nations at Lund, and there wrote the work on which his fame now rests, *De Jure Naturæ et Gentium* (1672), a work based upon the system of Grotius (q.v.), but completed and extended in the line of Hobbes' speculations. Some years later the king of Sweden made him his historiographer, with the dignity of a councillor of state. In his official character he published a dry history of Sweden, from the expedition of Gustavus Adolphus into Germany to the death of Queen Christine. In 1688 the Elector of Brandenburg invited him to Berlin to write the history of the life and reign of the Great Elector. He died in that city on 26th October 1694.

See Lorimer, *Institutes of Law of Nations* (vol. i. 1883); H. von Treitschke, in *Preussische Jahrbücher* (1875); and Droysen, *Abhandlungen zur neueren Geschichte* (1876).

Puffin (*Fratercula*), a genus of birds of the Auk family, characterised by a gaily-coloured bill —red, orange-yellow, and bluish gray—with a horny frontal sheath divided by transverse grooves

Puffin (*Fratercula arctica*).

into several distinct pieces. At the end of the breeding season these furrows deepen, and the sheath is shed. There is in fact an annual moult of the bill-sheath and of the horny plates above and below the eyelids. In form, size, and colour the new bill-sheath differs markedly from the old one. The genus Fratercula embraces three

species, of which only one, the Common Puffin (*F. arctica*), a bird a little larger than a pigeon, frequents the rocky shores of the Atlantic Ocean. It occurs in many parts of England and in Wales, while on the coast and islands of Scotland and Ireland it is often abundant, especially at the breeding season, when the birds congregate in large colonies. The egg, which is of a dull white marked with pale brown or lilac, is laid sometimes in a crevice of a cliff, sometimes in the burrow of a rabbit, or in a cavity made for the purpose. The nestling, which is covered with sooty black down, remains in the nest for three weeks, and is fed on small fishes. The adult birds feed on crustaceans and other marine animals. On land they waddle rather than walk, but they swim and dive well, and their flight is rapid though seldom high. In various localities the puffin is popularly called *Sea-parrot*, *Coulternebb*, and *Tammienorie*. In the Pacific the genus is represented by the Horned Puffin (*F. corniculata*). There also is found the closely allied genus Lunda, with bright yellow bill. The eggs of the puffin are much sought after, and the flesh of the young birds is used as food. For details as to the strange moulting and renewal of the bill, see *Zoologist* (July 1878).

Pug-dog. This breed of dog is generally supposed to have been brought over from Holland, where it is very common. Its origin there is unknown. The pug may be described as a miniature bulldog, though he differs in the shape of his ears, which should fall forward like a terrier's, and of his tail, which should curl tightly against his quarters. The broad under-jaw and wide skull of the bulldog are rarely seen, but should be present in a perfect specimen. Some years prior to 1860, when the pug was fashionable, Mr Morison of London and Lord Willoughby d'Eresby paid great attention to the breeding of pugs, and founded two distinct strains known as the Morison and Willoughby pugs. Large prices were paid for pure specimens of either strain, but when the fashion in ladies' dogs took another direction prices came rapidly down. The two strains have been so often recrossed that it is difficult to obtain a pure specimen now. The pug is only fit for a house-dog, as he is useless for any active work. Beyond a tendency to get very fat he is well fitted for this, as his short, smooth coat is easily cleaned, and he is a handy size.

Puget Sound, a large inland sea in the north-west of Washington, U.S., communicating with the Pacific by the Admiralty Inlet and Juan de Fuca Strait. It is divided into several branches, penetrates far into the interior, and is everywhere navigable for the largest vessels, which in most places can ride close to the shores, and load or unload without wharves. Great quantities of pine and fir are shipped from a country rich in timber.

Pugilism, or Boxing (Lat. *pugil*, 'a boxer;' compare 'pugnacity,' from *pugnus*, 'a fist'). 'To box' is almost as old as our language itself: no special explanation is required to show what boxing is; every one knows that it is fighting—real or mimic—with the hands alone, all weapons being foreign to the 'science.' As pugilism, in what has always been its highest standard—prize-fighting—is now supposed to be extinct, it may be of interest to give a brief sketch of its past, when it played a more important part—or was thought to do so—than it does now in the formation of the national character.

Although now the taste for it seems quite as firmly implanted in the colonies and in the United States, England has been emphatically the home of pugilism; and it is certain that in no other country at any time was such a fair, manly, and humane system of combat established as that under which the English settled their quarrels, especially after the rules of the prize-ring were issued. These, known now as the 'old rules,' dated from the time of the first recognised champion of England, in whose name they were framed to ensure regularity and fair-play in prize-fights, and, as a necessary consequence, in all others, the P.R.—an accepted abbreviation for Prize Ring—being the standard authority in such matters, the royal academy of athletics, as it were. This was soon after 1740, and the rules held good for nearly a century; but in 1838, after a fatal battle, they were revised, entirely in the direction of diminishing the danger of such contests. At the same time it should be remarked—and those unacquainted with the subject may possibly be surprised to learn—that fatal results to prize-fights were extremely rare, and in most instances occurred through what may be termed accidental or secondary causes. In Broughton's rules 'minute time' was allowed between the rounds—each bout of the struggle being called a 'round,' and lasting until one or both of the men were down; but this was altered in the new rules to half a minute. It was properly decided that if a man could not recover himself sufficiently in that time to face his antagonist he must be so weak or stupefied that further fighting would be dangerous. In Broughton's time, too, the seconds were allowed to carry their principals to the 'scratch;' this was forbidden by the new rules on the same grounds as the previous alteration. The purpose of both sets of rules was to secure fair-play and to foster a kind of rude chivalry, objects not without value when we remember the classes most likely to come under their influence, and the angry quarrels either code was intended to regulate. No man was to be struck while he was down; and no man might be struck below the belt—the belt in practice being a handkerchief tied tightly round the waist. With prize-boxers these handkerchiefs were the 'colours' of the men, chosen by themselves and worn by their partisans. Kicking, biting, and the horrible 'gouging'—once so frequent across the Atlantic, but now happily seldom heard of, owing to the spread of pugilism—were all 'foul,' and their practice instantly lost a man the battle. There were two seconds, or, as they were sometimes called, bottle-holders, to each man: their duty was to lift their principal when he fell; to carry him to his corner—always selected by tossing a coin, the winner of the toss naturally choosing the side of the ring which placed him with his back to the sun; to sponge or sprinkle him with water; to wipe the perspiration or blood from his face; and, as their second title implies, to refresh him with sips from the water or brandy bottle. They used also to carry in their jacket pockets a supply of powdered resin, which the boxer would rub on his hands to enable him to clench them tightly when he grew tired; but this practice was made 'foul' by the new rules. The 'scratch,' to which allusion has been made, was a mark in the centre of the ring which the combatants had to 'toe,' face to face, before hostilities could commence. It was also an indispensable formality for the men and their seconds to shake hands prior to the first round, all six crossing hands to do so, something like one of the figures in the Caledonian quadrilles; this prevented anything like a sudden rush by either of the men upon his unprepared foe. The 'ring' itself was a square of 24 feet, marked out by four corner and four middle stakes, round which ran two ropes at a height from the ground of 2 and 4 feet respectively.

For many years prize-fighting maintained an enormous popularity, and an existence which, if not actually legal, was scarcely to be distinguished

from it. The popularity perhaps remains, but the legality or the want of it is so settled that the P.R. is generally regarded as a thing of the past; and even boxing may be prohibited. 'Boxing' was once equivalent to 'pugilism,' the general term for 'fistic' manœuvres, but is now almost exclusively reserved for 'sparring' with padded gloves. These, of course, are used to prevent the injuries which the naked knuckles might inflict, although a very respectable amount of punishment can be dealt even with the largest gloves. Broughton was followed by a series of champions, amongst whom the most famous were probably John Jackson (1769–1845)—known as Gentleman Jackson; Jem Belcher; Tom Cribb (1781–1848), the most fearless, honest, and simple-minded of gladiators; Spring; and Tom Sayers (1826–65), with whom the series practically closed. All these have been honoured with handsome monuments, especially Jackson and Cribb, who lie respectively in Brompton Cemetery (London) and Woolwich churchyard; while the funeral of Sayers was almost a national demonstration, the heterogeneous procession which followed being one of the longest, if not actually the largest ever seen even in London. Another boxer, John Gully (1783–1863), might have been champion, but he retired from the ring and actually became M.P. for Pontefract (1832–37), an owner of extensive coal-mines, and, what to many of his admirers was a fact of much greater importance, his racers thrice won the Derby; and he began life as a journeyman butcher! The popular idol at one time was Jack Shaw (1789–1815), the life-guardsman, a pugilist of herculean strength, but not so polished in science as some of his compeers. His patrons offered to buy him out of the regiment when it was ordered abroad, and to back him for the championship; but the heroic guardsman refused, and, with thousands of his comrades, fell in winning the crowning victory for his country. It is said that he killed, or placed *hors de combat*, ten French cuirassiers at Waterloo before he was himself slain. Many men of the highest standing have deemed it essential to preserve the prize-ring. The great Duke of Wellington was its firm supporter; Sir Robert Peel and Lord Palmerston lent their influence to it, and Lord Byron, who was a pupil of Jackson, refers to him in really a respectful style in the notes to *Don Juan*. George Borrow's fight with the 'Flaming Tinman' is truly Homeric; and he lauds boxing as he lauds all things English. Thackeray, too, whose nose is said to have been broken in a school fight with a future church dignitary, devoted one of his *Roundabout Papers* to the fight between Sayers and Heenan. It would occupy too much space to continue this catalogue of admirers, but did we do so it would show how different was the popular tone of thought not so very long ago.

The P.R. may undoubtedly claim to have furnished an item in English history; for when the allied sovereigns visited London after the peace of 1814—the most important and brilliant gathering of potentates on record—it was deemed fitting by the highest authorities to show them a display of boxing, supported by the best pugilists of the day—a display greatly admired by the visitors. A year or two later the Grand-duke of Prussia saw a prize-battle and shook hands with the victor. The Shah of Persia in 1873 was also greatly delighted with a similar exhibition. The real decadence of the ring dates from the establishment of police in every county of England, which rendered it well-nigh impossible to 'get a fight off;' the leading patrons of the sport withdrew disgusted at the continual disappointment, leaving the boxers to the influence of a very different class. From the absence of any legal restraint, there had always been danger of disorder and riot, to check which no adequate force could be provided: yet latterly such scenes grew more frequent and worse in character, so that the demand from its opponents for the suppression of the ring gained in strength, while the efforts of those who would preserve it were proportionately weakened.

As with most other extensively followed games, the prize-ring had a dialect of its own, a 'flash lingo,' a few specimens of which may amuse the reader. The fists were 'mauleys,' and when both boxers struck with the same hand at the same time, the blow was called, aptly enough, a 'counter-hit,' or only a 'counter.' When one struck with the right and the other with the left at the same time, the blow was a 'cross counter.' 'Countering' was the most exciting, and the severest mode of inflicting punishment.

In consequence of the police difficulties attending prize-fights on the old lines, they have gradually drifted into exhibition matches, in which the 'gate' is an important factor. These fights are conducted under the Queensberry rules, so called from the marquis of that name who first drew them up (about 1890). They modify the conditions considerably, and as gloves are used (thinly stuffed, from 4 to 6 ounces in weight) they are nominally boxing contests and are presumably legal. They generally end in one of the combatants being 'knocked out'—that is, rendered insensible long enough to be unable to continue the fight. A blow on the point of the jaw or on the heart or stomach is the usual method of accomplishing this end. They are generally conducted under the auspices of some athletic club on a platform enclosed with a 24-feet ring, a charge being made for admission. They are very popular in the United States, where the biggest fights have taken place, such as that in which Fitzsimmons beat Corbett in 1897, and when Jeffries beat Fitzsimmons in 1899. In the latter case the money drawn for admission amounted to $75,000 (£15,000), of which sum over £12,000 was divided between the pugilists.

O'Reilly, *Ethics of Boxing and Manly Sport;* and Pollock and Grove's *Fencing, Boxing, and Wrestling* (Badminton Library, 1889); R. G. Allanson-Winn, *Boxing* (Isthmian Library, 1897).

Pugin, Augustus Welby, architect, was born in London on 1st March 1812, the son of a French architect, Augustin Pugin (1762–1832), in whose office, after schooling at Christ's Hospital, he was trained, chiefly by making drawings for his father's books on Gothic buildings. Whilst working with Sir C. Barry he designed and modelled a large part of the decorations and sculpture for the new Houses of Parliament (1836–37). Early in life he became a convert to Roman Catholicism; and most of his plans were made for churches and other ecclesiastical edifices belonging to that communion, the most successful being perhaps a church at Ramsgate, Killarney Cathedral, Adare Hall in Ireland, and the Benedictine chapel at Douai. He died insane at Ramsgate, on 14th September 1852. He enriched the literature of his profession by *Contrasts . . . between the Architecture of the 15th and 19th Centuries* (1836), a *Treatise on Chancel Screens* (1851), and *The True Principles of Christian Architecture* (1841). See B. Ferrey's *Recollections of A. W. Pugin and his Father* (1861).

His son, Edward Welby Pugin (1834–75), succeeded to his father's practice, and was the architect of many Roman Catholic churches, &c.

Pulaski, CASIMIR, a Polish count who fell in the American revolution, was born in Podolia, 4th March 1748, took an active part in the war against Russia, and lost his estates and was outlawed at the partition of Poland in 1772. In 1777 he went to America, and for his conduct at the Brandywine was given a brigade of cavalry, which he commanded until March 1778. He then organised 'Pulaski's legion,' a corps of lancers and light infantry, in which he enlisted even prisoners of war and deserters. In May 1779 he entered Charleston, and held it until the place was relieved; a furious assault which he had made on the British was repelled, but he afterwards followed and harassed them until they left South Carolina. At the siege of Savannah on the 9th of October he fell in the assault at the head of the cavalry, and died on board the brig *Wasp* two days later. In 1824 Lafayette laid the corner-stone of a monument to Pulaski, in Savannah, which was completed in 1855.

Pulci, LUIGI, an Italian poet, born at Florence, 3d December 1432, and died in 1484 (or 1487), was an intimate friend of Lorenzo de' Medici and of Politian. He is the author of a celebrated poem, *Il Morgante Maggiore* ('Morgante the Giant'), a burlesque epic of which Roland is the hero. This poem is one of the most valuable sources for the early Tuscan dialect, the niceties and idioms of which have been employed by Pulci with great skill (see ITALY, Vol. VI. p. 254). The first edition appeared at Venice in 1481, and the book has since been frequently reprinted. Pulci wrote further a humorous novel (printed in *Classici Italiani*, Milan, 1804) and several humorous sonnets.—His brother BERNARDO (born *circa* 1430) wrote an elegy on the death of Simonetta, mistress of Julian de' Medici, and the first translation of the *Eclogues* of Virgil. —LUCA, another brother (born 1431), wrote a poem in honour of Lorenzo de' Medici's success in a tournament; *Il Ciriffo Calvaneo*, a metrical romance of chivalry; *Driadeo d'Amore*, a pastoral poem; and *Epistole Eroiche*.

Pulex. See FLEA.

Pulicat, a town of British India, 20 miles N. of Madras, the first settlement of the Dutch in India; pop. 4967. It stands on an island in a large inlet of the sea called the Lake of Pulicat.

Pulko'wa, a village of Russia, 10 miles S. of the site of a magnificent observatory (59° 46′ 18″ N. lat. and 30° 19′ 40″ E. long.), the 'St Petersburg observatory,' built by the Czar Nicholas in 1838–39. In 1882 one of the largest telescopes in the world was erected here.

Pulley, one of the mechanical powers, consists of a wheel, with a groove cut all round its circumference, and movable on an axis; the wheel, which is commonly called a *sheave*, is often placed inside a hollow oblong mass of wood called a *block*, and by the sides of this block the extremities of the axle of the sheave are supported; the cord which passes over the circumference of the sheave is called the *tackle*. Pulleys may be used either singly or in combination; in the former case they are either *fixed* or *movable*. The *fixed pulley* (fig. 1) gives no mechanical advantage; it merely changes the direction in which a force would naturally be applied to one more convenient: thus, W can be raised without lifting it directly by merely pulling P down. The *single movable pulley*, with parallel cords, gives a mechanical advantage = 2 (fig. 2); for a little consideration will show that, as the weight, W, is supported by two strings, the stress on each string is ½W, and the stress on the one being supported by the hook, A, the power, P, requires merely to support the stress on the other string, which passes round C. The fixed pulley, C, is only of service in changing the naturally upward direction of the power into a downward one. If the strings in the single movable pulley are not parallel there is a diminution of mechanical advantage—i.e. P must be more than half of W to produce an exact counterpoise; if the angle made by the strings AB and BC is 120°, P must be equal to W; and if the angle be greater than this there is a mechanical disadvantage, or P must be greater than W. The following are examples of different combinations of pulleys, generally known as the first, second, and third systems of pulleys. In the first system one end of each cord is fastened to a fixed support above; each cord descends, passes round a pulley (to the lowest of which the weight, W, is fastened), and is fastened to the block of the next pulley, with the exception of the last cord, which passes round a fixed pulley above, and is attached to the counterpoise, P. The tension of a string being the same in all its parts, the tension of every part of the string marked (1) in fig. 3 is that which is produced by the weight of P; consequently, as the last movable pulley is supported on both sides by a string having a tension, P, the tension applied in its support is 2P. The tension of the string marked (2) is therefore 2P, and the second movable pulley is supported by a force equal to 4P. It may similarly be shown that the force applied by the strings marked (4) in support of the last pulley (which is attached to W) is 8P. Hence we see that, according to this arrangement, 1 lb. can support 4 lb. if two movable pulleys are used; 8 lb. if there are three movable pulleys; 16 lb. if there are four movable pulleys; and if there are n movable pulleys 1 lb. can support 2^n lb. It must be noticed, however, that in practice the weight of the cords, and of the pulleys, and the friction of the cord on the pulleys must be allowed for; and the fact that in this system all of these resist the action of the power, P, and that to a large extent, has rendered it of little use in practice.—The second system is much inferior in producing a mechanical advantage, but it is found to be much

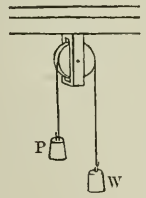

Fig. 1.

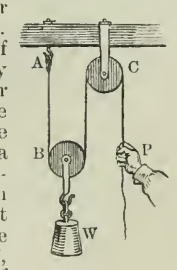

Fig. 2.

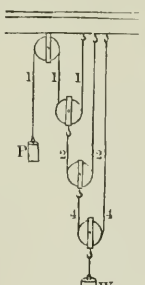

Fig. 3.

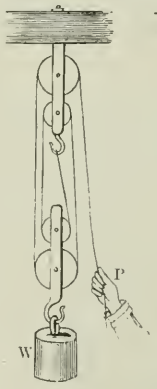

Fig. 4.

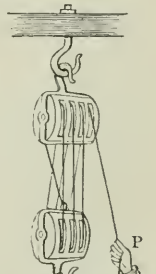

Fig. 5.

more convenient in practice, and is modified according to the purpose for which it is to be used; two prevalent forms are given in figs. 4 and 5. In this system one string passes round all the pulleys, and, as the tension in every part of it is that produced by the weight of P, the whole force applied to elevate the lower block with its attached weight, W, is the weight P multiplied by the number of strings attached to the lower block; in fig. 4 W = 4P, and in fig. 5 W = 6P, the pulleys in the upper block being only of use in changing the direction of the pulling force. This system is the one in common use in architecture, in dockyards, and on board ship, and various modifications of it—such as White's pulley, Smeaton's pulley, &c.—have been introduced; but the simpler forms shown above have been found to answer best.—The third system (fig. 6) is merely the first system inverted, and it is a little more powerful, besides having the weight of the pulleys to support the power, instead of acting in opposition to it, as in the former case.—The mechanical advantage can be traced out by finding from the form of the combination the ratio between the run of the tackle over the last sheave and the vertical ascent of W, when motion is set up. Theoretically, the larger the number of movable pulleys in any one combination the greater is the mechanical advantage afforded by it; but the enormous friction produced, and the want of perfect flexibility in the ropes, prevent any great increase in the number of pulleys.

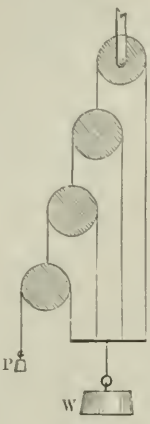

Fig. 6.

Pullman, George Mortimer, the inventor of the well-known 'cars,' was born in New York state in 1831, engaged in the business of moving and raising buildings, and as early as 1859 made his first sleeping-cars, and in 1863 the first on the model with which his name is now associated (see Railways). The Pullman Palace-car Company was formed in 1867, under his presidency, and now works nearly 1500 cars. In 1880 he founded an industrial town near Chicago, by which it has since been absorbed. On the 19th of October 1897 he dropped down dead in the streets of Chicago.

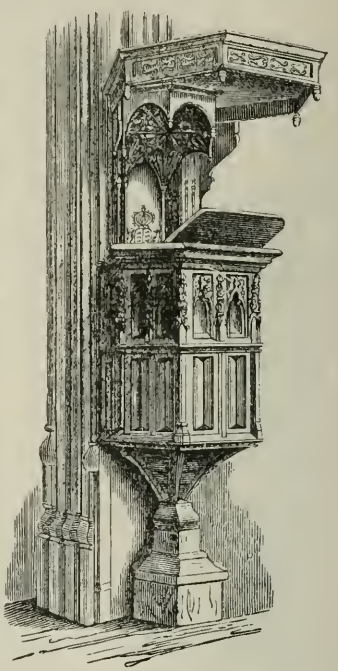
Pulmonates. See Gasteropoda.

Pulo-Penang. See Penang.

Pulpit (Lat. *pulpitum*), an elevated tribune or desk, from which sermons, lectures, and other solemn religious addresses are delivered. In great churches the pulpit is commonly placed on the north side of the nave against the wall, or in juxtaposition with a pillar or buttress (see also Ambo). The pulpits of the Low Countries and of Germany are often masterpieces of elaborate carving in wood and stone, frequent subjects for treatment being the Conversion of St Paul, the Call of Peter and Andrew, and Adam and Eve (as in the wood-carved pulpit by Verbruggen in St Gudule at Brussels). Sometimes the canopy or sounding-board is the part most elaborately adorned by carving in wood or stone, as in the pulpit at Fotheringhay, Northamptonshire. Amongst the masterpieces of Niccola Pisano are the beautifully wrought marble pulpits of the baptistery at Pisa, and of the cathedral at Siena. Some are adorned by bronze-work. The pulpit (in Arabic, *mimbar*) forms one of the scanty appliances of Mohammedan worship. See Dollman's *Examples of Ancient Pulpits in England* (1849).



Pulpit (Fotheringhay, Northamptonshire, 1440).

Pulque, a favourite beverage of the Mexicans and of the inhabitants of Central America and some parts of South America; made from the fermented juice of different species of Agave (q.v.).

Pulsatilla, or Pasque Flower, a species of Anemone (*A. pulsatilla*), of the natural order Ranunculaceæ. The species is a perennial herb with doubly pinnatifid or doubly trifid leaves, and a simple one-flowered scape. It is narcotic, acrid, and poisonous. The pulsatilla is a native of many parts of Europe, and of chalky pastures in several parts of England. It has widely bell-shaped bluish-purple flowers. Other species of Anemone have similar properties, *A. pratensis* and *A. patens*, the former a native of Europe generally, the latter of Siberia. They all emit, when bruised, a pungent smell, and contain, as their principal constituent, a peculiar pungent essential oil, which, in combination with *Anemonic Acid*, forms an acrid and very inflammable substance called *Anemonine* or *Pulsatilla Camphor*, and is sometimes used in medicine. *Pulsatilla* is a favourite medicine of the homœopathists. Easter eggs are coloured purple in some places with the petals of the pasque flower.

Pulse (Lat. *puls*), a name for the edible seeds of leguminous plants, as *corn* is the name for the edible seeds of grasses. Peas and beans are the most common and important of all kinds of pulse; next to them may be ranked kidney-beans, lentils, chick-peas, pigeon-peas, &c. The best kinds of pulse are very nutritious, but not easy of digestion, and are very apt to produce flatulence.

Pulse (Lat. *pulsus*, 'a pushing or beating'). The phenomenon known as the arterial pulse or arterial pulsation is due to the distension of the arteries consequent upon the intermittent injection of blood into their trunks, and the subsequent contraction which results from the elasticity of their walls. It is perceptible to the touch in all excepting very minute arteries, and, in exposed positions, is visible to the eye. The pulse is usually examined at the radial artery at the wrist, the advantages of that position being that the artery is very superficial, and that it is easily compressed against the bone. It is usual and convenient, though not quite accurate, to include under the term the conditions observed between the beats, as well as those produced by them.

The condition of the pulse depends mainly on two factors, each of which may vary independently of the other: *first*, the contraction of the heart, which propels the stream of blood along the artery; and *second*, the resistance in the small arteries and capillaries, which controls the rate at which it leaves the artery. The first determines the frequency and rhythm of the pulse and the force of the beats; but the tension of the artery between them and their apparent duration depend mainly upon the peripheral resistance. 'Feeling the pulse,' therefore, gives important information besides the rate of the heart's action, and implies much more than the mere counting of pulsations. Dr Broadbent says, 'A complete account of the pulse should specify (1) the frequency—i.e. the number of beats per minute, with a note of any irregularity or intermission or instability of the rhythm; (2) the size of the vessel; (3) the degree of distension of the artery between the beats; (4) the character of the pulsation—whether its access is sudden or gradual, its duration short or long, its subsidence abrupt or slow, note being taken of dicrotism when present; (5) the force or strength of both the constant and variable pressure within the artery, as measured by its compressibility; (6) the state of the arterial walls.'

The *frequency* of the pulse varies with age, from 130 to 140 per minute at birth to 70 to 75 in adult males, and with sex, being six or eight beats more in adult females. In some individuals it deviates considerably from this standard, and may even be habitually below forty or above ninety without any signs of disease. It is increased by exertion or excitement, by food or stimulants, diminished in a lying posture or during sleep. In disease (acute hydrocephalus, for example) the pulse may reach 150 or even 200 beats; or, on the other hand (as in apoplexy and in certain organic affections of the heart), it may be as slow as between thirty and twenty.

The normal regular *rhythm* of the pulse may be interfered with either by the occasional dropping of a beat (intermission), or by variations in the force of successive beats, and in the length of the intervals separating them (irregularity). These varieties often occur in the same person, but they may exist independently of each other. Irregularity of the pulse is natural to some persons; in others it is the mere result of debility; but it may be caused by the most serious disorders, as by disease of the brain, or by organic disease of the heart.

The other qualities of the pulse are much more difficult to recognise, though of no less importance. The degree of *tension* or resistance to compression by the fingers varies greatly: in a soft or 'low-tension' pulse the artery may be almost imperceptible between the beats; in a hard or 'high-tension' pulse it may be almost incompressible. An unduly soft pulse is usually an indication of debility; an unduly hard one is most characteristic of disease of the Kidneys (q.v.) and gout. But the tension, like the frequency of the pulse, undergoes considerable variations in health from temporary causes, and may in certain individuals be habitually above or below the average without actual disease.

The *force* of the beats is a measure of the vigour and efficiency of the heart's action. A strong pulse is correctly regarded as a sign of a vigorous state of the system; it may, however, arise from hypertrophy of the left ventricle of the heart, and remain as a persistent symptom even when the general powers are failing. As strength of the pulse usually indicates vigour, so *weakness* of the pulse indicates debility. Various expressive adjectives have been attached to special conditions of the pulse, into the consideration of which our space will not permit us to enter. Thus, we read of the jerking pulse, the hobbling pulse, the corded pulse, the wiry pulse, the thrilling pulse, the rebounding pulse, &c. The full significance of changes of the pulse in disease can only be appreciated by considering them in connection with the other signs and symptoms of the case. See MEDICINE (Vol. VII. p. 115), CIRCULATION, HEART, PALPITATION; and especially *The Pulse*, by Dr Broadbent (1890).

Pulsometer. See PUMPS.

Pulszky, FRANCIS AURELIUS, Hungarian politician and author, was born at Eperies, 17th September 1814, and after a course of legal studies travelled abroad, publishing (1837) a successful book on England. In 1848 he was appointed to a government post under Esterhazy, but, suspected of sharing in the revolution, fled to London, where he wrote for the papers. When Kossuth came to England Pulszky became his companion, and went with him to America (described in *White, Red, and Black*, 1852). His wife wrote *Memoirs of a Hungarian Lady* (Lond. 1850), and *Tales and Traditions of Hungary* (1851). He was condemned to death by the Austrian government in 1852, but, after living in Italy from 1852 to 1866, was pardoned in 1867. He has sat in the parliament, and been director of museums and libraries throughout the country. His autobiographic memoirs (4 vols. 1879–82) were translated into German. See F. W. Newman, *Reminiscences of Two Exiles* (1889).

Pulteney, WILLIAM, Earl of Bath. This statesman, descended from a Whig family, was born in 1684, the son of Sir William Pulteney, member of parliament for Westminster. He was a student of Christ Church College, Oxford, where his oratorical power was early displayed. He entered parliament as member for Heydon, Yorkshire, and was a most graceful and brilliant speaker, full of epigram, and a master of all the arts of parliamentary attack. At first, and for many years, the friend and colleague of Walpole, he finally became so disgusted with that minister's indifference to his claims that in 1728 he placed himself at the head of a small group of malcontent Whigs styled the 'Patriots,' and was henceforth Walpole's bitterest and perhaps most formidable opponent, being the leader of the coalition against him in the Commons as Carteret was in the House of Lords. He was Bolingbroke's chief assistant in the paper called the *Craftsman*, which involved him in many political controversies, and called forth some of his finest pamphlets. In 1731 he wrongly ascribed to Lord Hervey the authorship of a scurrilous pamphlet; a duel was the consequence, fought with swords in St James's Park, when both combatants were slightly wounded. On the resignation of Walpole in 1741 Pulteney was sworn of the Privy-council, and soon afterwards created Earl of Bath; and from that time his popularity was gone. Horace Walpole places him amongst his *Royal and Noble Authors*, but though his prose was effective and his verse graceful, he was probably still better known as the author of a once popular political song, 'The Honest Jury, or Caleb Triumphant,' than by his more serious writings. He died in 1764, a wealthy but disappointed man. See Lecky, *History of England*, ii. 417 *et seq.*, and *Walpole*, by John Morley.

Pultowa, or POLTA'VA, a town of Russia, situated on a tributary of the Dnieper, by rail 88 miles SW. of Kharkoff and 449 NE. of Odessa. It manufactures tobacco and leather, and has four annual fairs, the most important in July, when wool, horses, cattle, leather, hides, and coarse woollens and other stuffs are sold to the amount of £2,500,000 annually. Pop. 43,214. The town is a

bishop's seat, and is famous as the scene of Charles XII.'s defeat by Peter the Great on 27th June 1709.

Pultusk, a town of Poland, 32 miles N. of Warsaw. Here Charles XII. of Sweden defeated the Saxons in 1703, and here, too, on December 26, 1806, was fought a fierce battle between the Russians and the French, the latter being ultimately victorious. The town was destroyed by fire in 1875. Pop. 19,946.

Pulvermacher's Chains. See ELECTRICITY (MEDICAL).

Puma, or COUGUAR (*Felis concolor*), a large Carnivore distributed in North and South America between 60° N. and 50° S. lat., but rare in those parts which have been long settled. It is sometimes called the American 'lion,' 'panther,' ('painter'), or 'catamount,' and is about the size of a leopard. The fur is thick and close, dark yellowish red above, lighter on the sides, and reddish white on the belly; the muzzle, chin, throat, breast, and insides of the legs are more or less white. But the colouring varies a little in different localities. Young pumas have dark-brown spots in three rows on the back, and scattered markings elsewhere. The long tail is covered with thick fur, and is slightly coiled. The pumas have very diverse haunts—the forest, the bush, and the grassy pampas; they have no fixed lairs, but roam about by night from place to place in search of prey. They are agile in their movements, and can leap and spring well, but swim only under compulsion. Many kinds of mammals fall victims to the pumas, and they are the more disastrous to flocks and herds because of their habit of killing many more than they devour. To the booty which they have secured but merely tasted they will afterwards return. They rarely attack man, but one puma has been known to kill fifty sheep in a night, drinking a little of the blood of each; hence their extermination in many regions. The two sexes live apart, but pair in winter and summer. Two or three young are born at once, and are left a good deal to themselves, though after the first birth the mothers are certainly affectionate. In spite of its restless and voracious instincts the puma may be readily tamed, and is said to become gentle. The skin is sometimes used, and the flesh is occasionally eaten.

Pumice, a general term for the cellular, spongiform, filamentous, or froth-like parts of lavas. This highly porous and froth-like structure is due to the abundant escape of vapours through the rock while it was in a state of fusion. Under the microscope the rock is seen to be a glass, crowded with minute gas or vapour cavities and abundant crystallites. Owing to its porous structure pumice readily floats in water. It is usually a form of some highly acid lava, such as obsidian; but now and again basic lavas give rise to pumice (Canary Islands, Hawaii). The latter is dark brown or black, and often shows metallic tarnish; the former, which is much the more common, is white or gray, and sometimes yellow. It is a hard but brittle rock, and is much used for polishing wood, ivory, metals, glass, slates, marble, lithographic stones, &c., in preparing vellum and parchment, and for rubbing away corns and callosities. Great quantities are exported from the Lipari Isles; and that from the quarries in the Peak of Teneriffe, 2000 feet above sea-level, is better and cheaper. Pumice occurs as the crust of some kinds of lava, and is often ejected in the form of loose cinders during volcanic eruptions. Sometimes immense quantities are thrown into the sea and are often floated for great distances. Eventually the cinders get water-logged and sink to the bottom. Abundant fragments were dredged up from abyssmal depths by the *Challenger* expedition. After the eruption and earthquake in the Straits of Sunda in 1883, the seaport of Folok Batoung was closed with a barrier of pumice 19 miles long, two-thirds of a mile broad, and from 13 to 16 feet deep.

Pumpernickel, a kind of rye-bread (made of unbolted flour), much used in Westphalia. The etymology is disputed.

Pumpkin. See GOURD.

Pumps, machines for lifting liquids to a higher level, include (1) the Lift or Suction Pump, (2) the Lift and Force Pump, (3) the Pulsometer, (4) the Chain-pump, (5) Spiral Pumps, (6) the Centrifugal Pump, (7) the Jet-pump, (8) the Persian Wheel, (9) Scoop-wheels.

(1) *The Lift or Suction Pump* (fig. 1).—A is the cylinder (the 'barrel'), closed or open at the top; B is a pipe (the 'suction-pipe') communicating with the water to be raised; C is a 'discharge-pipe,' which may be reduced to a mere spout; D is a valve, opening upwards only; E is another valve, also opening upwards only, and borne by F; F is the 'bucket,' a hollow cylindrical piece of wood or metal which is made, by leather or by hemp or other packing, to fit the barrel just so closely that water cannot travel between the bucket and the barrel; G is the piston-rod, driven by hand, steam, windmill, or animal power, and moving the bucket up and down in the barrel. Each upward stroke of the piston at first lifts air, of which none can travel back past the bucket; a partial vacuum is produced in B; water ascends in B until the external atmospheric pressure is balanced by the partial atmospheric pressure below D plus the weight of the water column in B; as F now descends, air gets to the upper side of the valve, and is lifted on the upstroke, and so on; so that, if the valve D be not more than at most 33 feet above the water below (in practice 25 feet or less), water will be, step by step, pushed up B by the external atmospheric pressure until the valve D is under water; thereafter the succeeding strokes of the pump operate on the water above D and force it into the discharge-pipe, C, the external atmospheric pressure keeping the space below D filled with water. The power expended is applied (1) in lifting water; (2) in overcoming the pump-friction; (3) in overcoming the water-friction; and, (4) where the pump is ill-shaped, in producing eddies and broken water. A lift-pump must be very carefully proportioned and constructed in order to utilise, in water-lifting, one-half of the whole power expended in working it. Such pumps must work slowly, so that the valves may close properly; and an air-vessel is, if C be not a mere spout, required on C so as to minimise shock and render the outflow less intermittent, by the compression and elastic expansion of the air contained in it. The outflow is also regulated by driving two or three pumps off the same shaft and properly timing their relative motions.

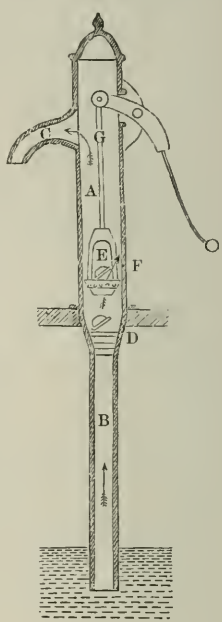


Fig. 1.

(2) *The Lift and Force Pump* (fig. 2).—The piston is solid, and the valve E, instead of being carried by the piston, is fitted in the discharge-pipe. During the downward motion of the piston water is forced past the valve E; it cannot return;

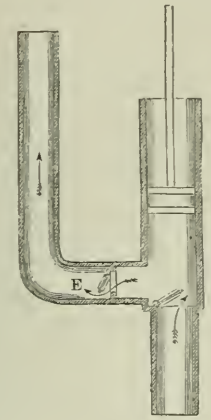

Fig. 2.

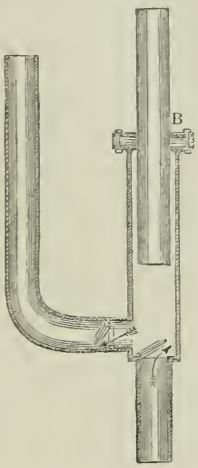

Fig. 3.

and water may thus be forced to considerable heights. Sometimes (fig. 3) the piston is made to fit, not the barrel, but the stuffing-box, B, which can be tightened down on it so as to make the fit good. An air-vessel, or a loaded hydraulic press called an 'accumulator,' is fitted on the discharge-pipe so as to minimise shock and intermittence; and double pumps are very generally employed, either directly driven by steam-engine pistons or driven by a flywheel. Force-pumps are used for deep wells and mines, hydraulic presses, boiler feeds, creasoting timber, hydraulic lifts, steam fire-engines both land and marine, and hydraulic power supply.

(3) *The Pulsometer.*—Two chambers, A and B, converge above and communicate with a single steam-pipe; a ball-valve shuts off either A or B, but not both at the same time, from the steam; A and B each have a discharge outlet and a suction inlet, both these having valves. The whole is filled with water; the steam drives water from, say, A into the discharge-pipe: condensation takes place and the ball-valve is pulled over, so as to shut off the steam from A: the steam then acts in B in the same way as it had done in A, while in the meantime A, where there is a partial vacuum, is being filled with water from the suction-pipe. The two chambers thus act alternately. The whole contrivance can be hung by chains and let down to the required position; and it is greatly in use in contractors' work.

(4) *The Chain-pump.*—This pump is formed of plates called lifts or buckets, fastened, now generally by their centres, to an endless chain and moving upwards, in a case or 'barrel' which is in places constricted so as just to let the buckets pass. Chain-pumps are noisy and somewhat apt to break down; but they can lift very gritty or muddy material. Dredging-machines (q.v.) with their buckets are a variety of this device.

(5) *Spiral Pumps.*—An Archimedes' Screw (q.v.) is rotated round its axis so as to make water slip up the inclined plane of the screw. They are very economical in power, and they work so regularly that they act as meters.

(6) *Centrifugal Pumps* (figs. 4 and 5).—The water enters by the supply-pipes, A, A, which lead to the central orifices of the fan, B, B; it then traverses the passages, C, C, formed by the vanes and the side covering-plates, D, of the fan. The fan is made to rotate from the shaft, E. The water acquires a rotatory motion while passing through the passages of the rotating fan; it then enters the whirlpool-chamber, F, and is discharged by the pipe, G, at the circumference of F; and the velocity of

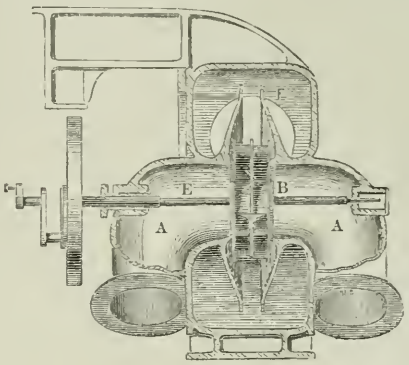

Fig. 4.

rotation of the fan determines the height to which the water will rise in the discharge-pipe. This velocity cannot conveniently be made to exceed a certain limit; hence the utility of centrifugal pumps is practically limited to low lifts; but as they can be made very large they can deal with enormous quantities of water; and they are much used for pumping in docks, canals, marsh and polder draining, land-reclaiming, and the like. As they have no valves they are little liable to become choked. In nearly all modern centrifugal pumps the whirlpool-chamber, F, the purpose of which was to reduce the ultimate velocity of outflow and correspondingly to increase the pressure, is dispensed with; and the same end is attained without wasting energy through friction in the vortex, F, by shaping the vanes of the fan so as to reduce the velocity. See Cotterill's *Applied Mechanics.*

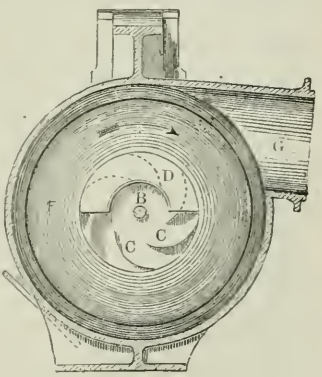

Fig. 5.

(7) *The Jet-pump*, now not much used, is practically a Giffard's Injector (q.v.) worked by water from a height instead of by steam.

(8) *The Persian Wheel.*—An under-shot wheel (mill-wheel in which the water flows under the wheel) in which little buckets are carried by the rim of the wheel so as to pick up water from the stream and deliver it at the top of the wheel.

(9) *Scoop-wheels* or flash wheels: equivalent to breast water-wheels with reversed action; driven by windmills or by steam, they raise water in their buckets and deliver it a few feet higher up; in some cases they have curved blades, and the water is delivered at the centre of the wheel.

See *Pumps and Pumping Machinery*, by Frederick Colyer, C.E. (Lond. 1886); also see AIR-PUMP.

Pun, the name given to a play upon words that agree or resemble each other in sound but differ in sense, a verbal quibble by means of which an incongruous and therefore ludicrous idea is unexpectedly shot into the sentence—as, for example, in the answer to the grave question, 'Is life worth living?' —'That depends on the liver.' We find this form of witticism in Aristophanes and Cicero, and in old England it was not unknown even in the pulpit. The sermons of Bishop Andrewes and the *Church History* and other works of Thomas Fuller abound in puns of all degrees of goodness and badness; they meet us strangely enough even in the gravest situations in the tragedies of Shakespeare, and there is at least one in Liddell and Scott's *Greek Lexicon*. Dr Johnson said that the man who would make a pun would pick a pocket; but this sentence bears too hard upon the best beloved of English writers, Charles Lamb, a hardened punster, not to speak of Sydney Smith, Hook, Hood, the prince of punsters, and Bishop Wilberforce. Boswell, while relating Dr Johnson's dislike to puns, ventures his own opinion that 'a good pun may be admitted among the smaller excellencies of conversation.' But a pun of the best kind has a value infinitely higher than this: there is tenderness as well as wit in Fuller's phrase of the Holy Innocents of Bethlehem—'the *infantry* in the noble army of martyrs.'

See *Spectator*, No. 61, L. Larchey's *Les Joueurs des Mots* (1866), and Holmes's *Autocrat of the Breakfast Table*. The Hon. Hugh Rowley's *Puniana* (1867) and *More Puniana* (1875) contain many hundred examples, among them a few good puns.

Punch, a beverage introduced into England from India, and so called from being usually made of five (Hindi, *panch*) ingredients—arrack, tea, sugar, water, and lemon-juice. As now prepared, punch is a drink the basis of which is alcohol of one or more kinds (especially rum), diluted with water, flavoured with lemon or lime-juice and spices, and sweetened with sugar; sometimes other ingredients are added according to taste, especially wine, ale, and tea. 'Rack-punch' takes its name from Arrack (q.v.). Milk-punch is prepared beforehand (of rum and brandy with milk), bottled, and served cold—even iced. Whisky-toddy, made with whisky, hot water, and sugar, is a kind of punch, the name *toddy* being Hindustani.

Punch, with his wife Judy and dog Toby, the chief characters in a popular comic puppet-show, of Italian origin, the name being a contraction of Punchinello, for Pulcinello, the droll clown in Neapolitan comedy. The word is a diminutive from *pulcino*, 'a young chicken.' The identification with Pontius Pilate, as well as of Judy with the betrayer Judas, is entirely without foundation. Many believe the modern Punch to have originated in a survival of the Maccus, the fool or clown of the ancient Atellanæ (q.v.), just as the Italian Arlecchino and Brighetta are of their other Oscan characters. But the line of descent is certainly obscure enough, and it is at least not improbable that some trace of the old *Ludi Osci*, transmitted through the Vice of the mystery plays, may lurk in the modern drama of the hook-nosed hunchback Punch and his unfortunate wife Judy. The full-grown modern drama, which can scarcely be looked on as a school of the domestic virtues, is ascribed to an Italian comedian, Silvio Fiorillo, about 1600. The exhibition soon found its way into other countries, and was very popular in England during the 17th century. Its popularity seems to have reached its height in the time of Queen Anne, and Addison has given in the *Spectator* a regular criticism of one of the performances. In 1812 Ouseley saw at Tabriz in Persia a Gypsy puppet-show very like our Punch and Judy. See also MARIONETTES.

The performance of Punch, as generally represented, requires the assistance of only two persons —one to carry the theatre and work the figures, the other to bear the box of puppets, blow the trumpet, and sometimes keep up the dialogue with the hero of the piece. The movements of the puppets are managed simply by putting the hands under the dress, making the second finger and thumb serve for the arms, while the forefinger works the head.

Punch, or the LONDON CHARIVARI, the English comic journal *par excellence*, is a weekly magazine of wit, humour, and satire in prose and verse, copiously illustrated by sketches, caricatures, and emblematical devices. It draws its materials as freely from the most exalted spheres of foreign politics as from the provincial nursery; and, dealing with every side of life, is not less observant of the follies of Belgravia than of the peculiarities of Whitechapel. *Punch* gives due place to Irish bulls and dry Scotch humour, and does its best to present them in the raciest vernacular. Stern in the exposure of sham and vice, *Punch* is yet kindly when it makes merry over innocent foibles. Usually a *censor morum* in the guise of Joe Miller, a genial English Democritus who laughs and provokes to laughter, *Punch* at times weeps with those that weep, and, *jocis remotis*, pays a poetical tribute to the memory of the departed great. The wittiest of serial prints was founded in 1841, the first number appearing on the 17th July of that year, and, under the joint editorship of Henry Mayhew and Mark Lemon, soon became a household word, while ere long its satirical cuts and witty rhymes were admittedly a power in the land. *Punch* is recognised as an English institution, and in corners of Europe where an Englishman rarely comes the frequenters of the café may be seen puzzling over the esoteric wit and wisdom of Cockayne. Their contributions to *Punch* helped to make Douglas Jerrold, Gilbert à Beckett, Tom Hood, Albert Smith, Thackeray, Shirley Brooks, Tom Taylor, and F. C. Burnand famous; as their illustrations did H. K. Browne, Doyle, Leech, Tenniel, Du Maurier, Keene, Linley Sambourne, and Furniss. It should be noted that this genial comic paper has done memorable service in purifying the moral standard of current wit in England.

See CHARIVARI, CARICATURE, the articles on the chief contributors, &c.; *A Jorum of Punch*, by Athol Mayhew, rather unduly magnifying Mayhew's share (1895); and *The History of Punch*, by M. H. Spielmann (1895).

Punchestown, a racecourse close to Naas, 20 miles SW. of Dublin, where are held in April the steeplechases of the Kildare Hunt. There are stone monuments near.

Punctuation is the art of marking the divisions of a sentence by means of conventional signs —the full stop or period (.), colon (:), semicolon (;), comma (,), dash (—), mark of exclamation (!), mark of interrogation (?), inverted commas (" "), and brackets—( ), [ ]. Broadly speaking, there are two principal systems of punctuation, the grammatical and the logical. The system most frequently followed in British printing-houses is neither of these, being a set of empirical rules, in which the logical element is almost entirely wanting, the grammatical is present to some extent, but the ruling factor is apparently arbitrary fancy. Commas are too often held in profound contempt, being scattered at random amongst the words as if from a pepper-box. These lawless little adjuncts can be found, in the *best-printed* books, insinuating themselves between subject and verb in even short sentences. The printing-offices of the United States are to some extent uniform in their practice. The system they follow is much better than those in

Britain, and is based principally upon grammatical laws. The old-fashioned method of putting in a comma (or even a stronger stop) wherever a reader would naturally pause to take breath when reading aloud (as at this point of this sentence) has little in reason to commend it. Punctuation is confessedly difficult, partly owing to the vast differences in the style of different writers, and partly owing to the conflicts between logical meaning and grammatical word-arrangement which in some cases are inevitable. Given a sensible system, practical experience is the best teacher. In theory little more can be done than to lay down a few general maxims for guidance.

In the first place, follow a logical method of sentence subdivision: let the first and foremost aim be to bring out the meaning clearly and unambiguously, in so far as this can be done with the help of stops. Use commas and semicolons sparingly, especially commas; use them, indeed, only where they are absolutely necessary. The sentence should stand on its own feet, not rest upon a long array of comma crutches. It is not as a general rule necessary to set commas to fence or adorn every adverbial clause. Especial care is required in punctuating sentences that contain relative clauses. If the relative sentence is entirely subordinate to the main sentence, or if it gives additional information, separate it by a comma or commas; if on the other hand it belongs essentially to the structure of the thought expressed by the main sentence, put no comma. For example, in 'the man who had an impediment in his speech,' written without the comma, the relative clause points out this particular man and distinguishes him from some other or others who have been also spoken of: it fulfils in fact the function of an article or demonstrative pronoun. In the same sentence printed with the comma, 'the man, who had' &c., the relative clause gives an entirely new piece of information, and is no longer demonstrative. The colon is generally put before a long quotation. It would be well to confine the use of it to this and to one other case—namely, to part a general statement from the immediately following particular application of it or exemplification of it in detail. As for dashes, it is difficult to summarise the rules for their use. They are commonly employed to indicate a sudden break or change in the grammatical structure or the logical development of the sentence, as well as to put ironical emphasis upon a word or words thrown to the end of the sentence, as in Heine's phrase, 'Göttingen is noted for its professors and its—sausages;' but even this would be better without such a clumsy advertisement of the humour. A dash may precede an enumeration of mere names or dates or objects expressed in very brief terms. One dash may also be put before and one after a short clause that merely explains in other words or makes clearer a statement that has just been made; both dashes, and not one dash and some other stop, should be used, except where the second would fall at the end of a sentence. But for this purpose, especially where the parenthetical nature of the added explanatory clause is more prominent, brackets are frequently employed. Semicolons are most appropriately used in compound sentences or sentences that embrace antithetical statements. In the former class of sentence they should mark off the subordinate sentences from the main sentence or co-ordinate sentences from one another; in the latter class they should separate the antithetical sentences, which generally begin with 'but' or some equivalent. The mark of exclamation has another besides its legitimate use: it is frequently put after absurd or highly improbable statements. The mark of interrogation too has a secondary use: placed in brackets immediately after a word it throws doubt upon its correctness, either as according with fact or as being philologically or grammatically correct.

Of course these are only general rules. Many exceptions even to them must necessarily occur. The golden rules in all cases of doubt are two: (1) let logic or, better, common sense be the supreme guide; (2) punctuate so as to bring out the sense best. It is greatly to be desired that British printing-houses would come to some agreement as to a uniform and systematic method of punctuation. See H. Beadnell's *Spelling and Punctuation* (4th ed. 1891).

Pundit (Hindi, *pandit;* Skr. *pandita*, 'a learned man'), in India a teacher, especially a Brahman learned in Sanskrit and in Hindu literature, law, and religion. Of late native pundits have done good service as geographical explorers in districts, such as Tibet, not accessible to Europeans.

Pungwe, a river of Portuguese East Africa, forming the principal waterway to Manicaland and Mashonaland; its mouth is situated some 25 miles NE. of Sofala and 130 SW. of the Zambesi delta. After some diplomatic difficulties between Britain and Portugal, it was agreed (1891) by Portugal that British commerce should have unimpeded access by this route to the British sphere in the interior, the Pungwe being made freely navigable for British vessels. In 1894 nearly 200 miles of the railway to the interior had been laid. See Beira.

Punic Wars. See Carthage.

Punishment will be found described in the articles in this work on Criminal Law, Imprisonment, Prisons (p. 420), Flogging, Execution, Pillory, &c. See also the description of Tortures, Boot, Guillotine, Thumb-screw, Branks, Jougs, Ducking-stool, Stocks, &c.; the articles on the several crimes; and W. Andrews, *Old-time Punishments* (1891). The question of future punishment is treated in the article Hell.

Punjab, or Panjab (*pánj-ab*, 'five rivers;' the *Pentapotamia* of the Greeks), a separate province of India, occupying the north-west corner, is watered by the Indus and its five great affluents —the Jhelum, Chenab, Ravi, Beas, and Sutlej. It is bounded on the W. by Afghanistan, on the N. by Cashmere, on the E. by the Jumna and the North-western Provinces, and on the S. by Rajputana and Sind. The area under direct British administration is 106,632 sq. m.; that of the native states, thirty-four in number, under British control is 35,817 sq. m. Pop. (1881) 18,850,437 in British province and 3,861,683 in the dependent states; (1891) 20,803,000 in British territory and 4,256,670 in the feudatory states. The capital is Lahore, but both Delhi (formerly in North-western Provinces) and Amritsar (the religious capital of the Sikhs) are larger. The whole of the northern parts are traversed by spurs from the Himalayas, which enclose deep valleys. On the west the Sulaiman Mountains run parallel to the Indus. In the south the surface is not broken by any important eminence, except the Salt Range, varying from 2000 to 5000 feet high, between the Indus and the Jhelum. The country, divided into six doabs, or interfluvial tracts, and frequently spoken of as the plains of the Indus, has a general slope towards the south-west. The climate in the plains is most oppressively hot and dry in summer, reaching in May 87·4° to 116·6° F. in the shade at several stations; but is cool, and sometimes frosty, in winter. Little rain falls except in the districts along the base of the Himalayas. The soil varies from stiff clay and loam to sand; but, in general, is sandy and barren, intermixed with fertile spots. Rivers and canals afford ample means of irrigation.

The indigenous vegetation is meagre. Trees are few in number and small, and fuel is so scarce that cow-dung is much used in its stead. Wheat of excellent quality is produced in considerable quantities, and indigo, sugar, cotton, tobacco, opium, tea, rice, barley, millet, maize, and numerous vegetables and fruits are grown. The manufacturing industry—cottons, wood-work, iron, leather, gold and silver lace, silk, and shawls—is very considerable, and is carried on for the most part in the great towns, as Amritsar, Lahore, Multan, &c. Punjab exports indigo, grain, salt, metals, spices, tea, tobacco, manufactured cottons, hides, and leather to Kabul, Cashmere, Turkestan, and Tibet; and imports dyes, goats' wool, raw silk, fruits, ghee, horses, furs, timber, and shawl cloth. The total value of this trade reaches annually £2,299,900. The inhabitants are of various races, chiefly Sikhs, Jats, Rajputs, and Pathans. Of the whole population, nearly 56 per cent. are Mohammedans; Hindus constitute nearly 38 per cent.; and Sikhs 6 per cent. The Jats are the most prominent race, and are said to have formed the 'core and nucleus' of the Sikh nation and military force. For the history of the Punjab, see SIKHS.

Punkah, a gigantic fan for ventilating apartments, used in India and tropical climates. It consists of a light frame of wood, covered with calico, from which a short curtain depends, and is suspended by ropes from the ceiling; another rope from it passes over a pulley in the wall to a servant stationed without; the servant pulls the punkah backwards and forwards, maintaining a constant current of air in the chamber.

Puno. See PERU, pp. 79–80.

Punt, a heavy, oblong, flat-bottomed boat, useful where stability and not speed is needed. Punts are much used for fishing and wild-fowling. Some are fitted for oars; but the more usual mode of propulsion is by poles operating on the bottom.

Punta Arenas, (1) the chief port of Costa Rica on the Pacific, stands on a 'sandy point' jutting into the Gulf of Nicoya, and is connected by railway with Esparza, 14 miles east-north-east. The principal export is coffee, and after that india-rubber, hides, dye-woods, and tortoiseshell. Pop. 8000.—(2) A town in Patagonia (q.v.).

Pupa (Lat., 'a doll'), the stage which intervenes between the larva and the adult in the life of insects with complete metamorphosis. *Chrysalis, aurelia, nymph* are almost synonymous terms, but pupa is more general and is sometimes applied to stages in the metamorphosis of other animals besides Insects (q.v.).

Pupil. See INFANT, and EYE, Vol. IV. p. 507; for Pupil-teachers, see EDUCATION.

Puppet. See MARIONETTES.

Purána (Sansk., 'old') is the name of that class of religious works which, besides the Tantras (q.v.), is the main foundation of the actual popular creed of the Brahmanical Hindus (see INDIA, Vol. VI. p. 106). According to the popular belief, these works were compiled by Vyása, the supposed arranger of the Vedas (q.v.), and the author of the Mahábhárata (q.v.), and possess an antiquity far beyond the reach of historical computation. A critical investigation, however, of the contents of the *existing* works bearing that name must necessarily lead to the conclusion that in their present form they not only do not belong to a remote age, but can barely claim an antiquity of a thousand years, though they contain materials much more ancient. Cosmogonic and theogonic doctrines, epic stories, legendary lore, and miscellaneous and encyclopædic matter constitute their contents. They all recognise the Hindu trinity, but are of sectarian tendency; the claims of one god or one holy place being in the various books or parts of them insisted on as worthy of special, if not exclusive, reverence. The Puránas are usually said to be eighteen in number (with a subordinate Upa-purána to each); and these are subdivided into three groups of six. The first two are devoted to Vishnu and to Siva; the third, which should have fallen to Brahma, is mainly devoted to the several forms of Vishnu, Krishna, Devi, Ganesa, and Surya. They are written in epic couplets, and the eighteen chief Puránas are calculated to contain 400,000 couplets.

See VISHNU, SANSKRIT LITERATURE; Dr John Muir's *Sanscrit Texts* (1858–71); the Vishnu Purána trans. by H. H. Wilson (1840; 2d ed. by Fitzedward Hall, 1864–77); the Bhágavata Purána, edited, with a French translation, by Burnouf and Hauvette-Besnault (4 vols. Paris, 1840–84), and, with a Sanskrit commentary, by Shridhar Pandit (3 vols. Bombay, 1887); the Márkandeya and Agni Puránas, in the *Bibliotheca Indica*, by Banerjea and Rájendralál Mitra.

Purbeck, ISLE OF, a peninsular district of Dorsetshire, 12 miles long and 5 to 9 broad, is bounded N. by the river Frome and Poole Harbour, E. and S. by the English Channel, and W. by the little stream of Luckford Lake, which runs from Lulworth Park to the Frome. The coast is bold and precipitous, with St Albans Head, 360 feet high; inland a range of chalk downs curves east and west, attaining a maximum height of 655 feet. The geology of the 'isle' is very interesting. The Purbeck Beds are a group of strata forming the upper members of the Jurassic System (q.v.); the Purbeck Marble, belonging to the upper section of these, is an impure fresh-water limestone, composed almost wholly of the shells of *Paludina carinifera* (see DIRT-BEDS). Nearly a hundred quarries are worked; and the quarrymen still form a curious kind of trades' guild. Of old the 'isle' was a royal deer-forest. Swanage and Corfe Castle are the chief places.

See Robinson's *A Royal Warren, or Rambles in the Isle of Purbeck* (1882), and J. Braye's *Swanage* (1890).

Purcell, HENRY, the most eminent of English musicians, was born at Westminster in 1658, and was son of Henry Purcell, one of the gentlemen of the Chapel Royal appointed at the Restoration. He lost his father at the age of six, and was indebted for his musical training to Cooke, Humfrey, and Dr Blow. His compositions at a very early age gave evidence of talent. In 1680 he was chosen to succeed Dr Christopher Gibbons as organist of Westminster Abbey; and in 1682 he was made organist of the Chapel Royal. He wrote numerous anthems and other compositions for the church, which were eagerly sought after for the use of the various cathedrals, and have retained their place to the present day. Purcell's dramatic and chamber compositions are even more remarkable. Among the former may be mentioned his opera *Dido and Æneas*, written at the age of seventeen, his music to the *Tempest*, his songs in Dryden's *King Arthur*, his music to Howard's and Dryden's *Indian Queen*, to D'Urfey's *Don Quixote*, &c. A great many of his cantatas, odes, glees, catches, and rounds are yet familiar to lovers of vocal music. In 1683 he composed twelve sonatas for two violins and a bass. Purcell studied the Italian masters deeply, and often made reference to his obligations to them. In originality and vigour, as well as richness of harmony and variety of expression, he far surpassed both his predecessors and his contemporaries. His style foreshadows that of Handel. His church music was collected and edited from the original MSS. by Vincent Novello, in a folio work which appeared in 1829–32, with a portrait and essay on his life and works. A complete edition of his

works, many of which are still in MS., was undertaken by the Purcell Society, instituted in 1876. Purcell died of consumption in 1695, and was buried in Westminster Abbey.

Purchas, SAMUEL, was born at Thaxted in Essex in 1577, and educated at St John's College, Cambridge. He was presented by the king in 1604 to the vicarage of Eastwood, which he soon resigned to his brother, as the chosen labour of his life required residence in London. Later he became rector of St Martin's, Ludgate, and chaplain to Archbishop Abbot, and died in September 1626, if not in a debtor's cell, yet in difficulties. His great works were *Purchas his Pilgrimage, or Relations of the World and the Religions observed in all ages* (1613; 4th ed. much enlarged, 1626), and *Hakluytus Posthumus, or Purchas his Pilgrimes: containing a History of the World, in Sea Voyages and Land Travels by Englishmen and others* (4 vols. folio, 1625). The fourth edition of the former usually accompanies the latter as if a fifth volume, although a quite distinct work. Purchas himself thus describes the two books: 'These brethren holding much resemblance in name, nature, and feature, yet differ in both the object and the subject. This [the *Pilgrimage*] being mine own in matter, though borrowed, and in form of words and method; whereas my Pilgrimes are the authors themselves, acting their own parts in their own words, only furnished by me with such necessaries as that stage further required, and ordered according to my rules.' Another work is *Purchas his Pilgrim: Microcosmus, or the History of Man; relating the wonders of his Generation, varieties in his Degeneration, and necessity of his Regeneration* (1619).

Purchase-system. See COMMISSIONS.

Purfleet, a village of Essex, on the north bank of the Thames, 15 miles by rail E. by S. of London and 8 miles E. of Woolwich, contains government powder-magazines, built in 1781.

Purgatives. See APERIENTS, CONSTIPATION.

Purgatory (Lat. *purgatorium*, from *purgo*, 'I cleanse') is the name given to a place of purgation, in which, according to the Roman Catholic and Oriental churches, souls after death either are purified from venial sins (*peccata venalia*) or undergo the temporal punishment which, after the guilt of mortal sin (*peccata mortalia*) has been remitted, still remains to be endured by the sinner (see ATONEMENT). The ultimate eternal happiness of their souls is supposed to be secured; but they are detained for a time in a state of purgation, in order to be fitted to appear in that Presence into which nothing imperfect can enter. Catholics hold as articles of their faith (1) that there is a purgatory in the sense explained above, and (2) that the souls there detained derive relief from the prayers of the faithful and from the sacrifice of the mass. The scriptural grounds alleged by them in support of this view are 2 Macc. xii. 43–46, Matt. xii. 32, Luke, xii. 48, 1 Cor. iii. 11–15, 1 Cor. xv. 29; as well as certain less decisive indications contained in the language of some of the Psalms. And in all these passages they argue not alone from the words themselves, but from the interpretation of them by the Fathers. The direct testimonies cited by Catholic writers from the Fathers are very numerous, from the days of Clement and Origen down; amongst the Latins Augustine being one of the most important (though at times he speaks doubtfully); in Gregory the Great the doctrine is found in all the fullness of its modern detail. The epitaphs of the catacombs, too, supply Catholic controversialists with some testimonies to the belief of a purgatory, and of the value of the intercessory prayers of the living in obtaining not merely repose, but relief from suffering, for the deceased; and the liturgies of the various rites are still more decisive and circumstantial. Beyond these two points Catholic faith, as defined by the Council of Trent, does not go; and the council expressly prohibits the popular discussion of the 'more difficult and subtle questions, and everything that tends to curiosity, or superstition, or savours of filthy lucre.' As to the existence of purgatory Greek and Latin churches are agreed; and they are further agreed that it is a place of suffering; but, while the Latins commonly hold that this suffering is 'by fire,' the Greeks do not determine the manner of the suffering, but are content to regard it as 'through tribulation.' The decree of union in the Council of Florence (1439) left this point free for discussion. Equally free are the questions as to the situation of purgatory; as to the duration of the purgatorial suffering; as to the probable number of its inmates; as to whether they have, while there detained, *a certainty* of their ultimate salvation; and whether a 'particular judgment' is passed on every one immediately after death. For Patrick's Purgatory, see DERG (LOUGH).

The mediæval doctrine and practice regarding purgatory were among the leading grounds of the protest of the Waldenses and other sects of that age. The Reformers as a body rejected the doctrine. Protestants generally reply to the arguments of Roman Catholics on the subject of purgatory by refusing to admit the authority of tradition or the testimonies of the Fathers, and at the same time by alleging that most of the passages quoted from the Fathers, as in favour of purgatory, are insufficient to prove that they held any such doctrine as that now held by the Roman Catholic Church, some of them properly relating only to the subject of prayer for the dead (see PRAYER), and others to the doctrine of Limbus (q.v.). That the doctrine of purgatory is the fair development of that which maintains that prayer ought to be made for the dead Protestants generally acknowledge. As to the alleged evidences from Scripture, they are commonly set aside by Protestants as irrelevant or wholly insufficient to support such an inference. The doctrine of purgatory in its historical connection with other eschatological doctrines is touched on in the article HELL.

Purging Nut. See PHYSIC NUT.

Purgstall. See HAMMER-PURGSTALL.

Puri. See JUGGERNAUT.

Purification of the Blessed Virgin Mary, FEAST OF, a festival in commemoration of the 'purification' of the Blessed Virgin Mary, in accordance with the ceremonial law of Lev. xii. 2. This ceremony was appointed for the fortieth day after childbirth, which, reckoning from December 25 (the nativity of our Lord), falls upon February 2, on which day the purification is celebrated. The history of Mary's compliance with the law is related in Luke, ii. 22–24. The date of the introduction of this festival is uncertain. The first trace of it is about the middle of the 5th century, and in the Church of Jerusalem. In the Western Church it was known to Bede. Its introduction in the Roman Church in 494 was made by Pope Gelasius the occasion of transferring to a Christian use the festivities which at that season were annexed to the pagan festival of the Lupercalia. See CHURCHING OF WOMEN.

Purim, a Jewish secular rather than religious feast, in honour of the deliverance of the nation, recorded in the Book of Esther, held on 14th to 15th Adar. Apparently it spread but slowly; still Josephus tells us that by his time it was observed over all the Jewish world. Most modern scholars

consider it an adaptation of a similar Persian feast, *Furdigan* ('Pôrdiyān'), and Lagarde has shown that the two names are identical. See ESTHER.

Puritans, a name first given, according to Fuller, in 1564, and according to Strype in 1569, to those clergymen of the Church of England who refused to conform to its liturgy, ceremonies, and discipline as arranged by Archbishop Parker and his coadjutors. The history of Puritanism within the church is sketched at ENGLAND (CHURCH OF), Vol. IV. pp. 358-359. In spite of the sharpest repressive measures, the principles of the party amongst the clergy who believed that the church did not separate itself markedly enough from Roman Catholicism and needed further reformation gradually spread among the serious portion of the laity, who were also called Puritans. But the name appears not to have been confined to those who wished for certain radical changes in the forms of the church. The character that generally accompanied this wish led naturally enough to a wider use of the term; hence, according to Sylvester, 'the vicious multitude of the ungodly called all Puritans that were strict and serious in a holy life were they ever so conformable.' This is the sense in which the Elizabethan dramatists use the word. From this very breadth of usage one sees that there were different degrees of Puritanism. Some would have been content with a moderate reform in the rites, discipline, and liturgy of the church; others (like Cartwright of Cambridge) wished to abolish Episcopacy altogether, and to substitute Presbyterianism; while a third party, the Brownists or Independents, were out-and-out dissenters, opposed alike to Presbyterianism and Episcopacy. During the reigns of James I. and Charles I. the spirit of Puritanism continued more and more to leaven English society and the English parliament, although the most violent efforts were made by both monarchs to extirpate it. Up till the time of the Synod of Dort (1618–19) both the Puritans and their opponents in the church had been substantially Calvinist; the strong tendency towards Arminianism amongst churchmen raised a new ground of controversy between the Puritans and the other sections of the church, both Laudian and Latitudinarian. The policy of Laud and the outrages practised by Charles on the English constitution led many who were not at all Genevan in their ideas to oppose both church and king for the sake of the national liberties. In the memorable 'Westminster Assembly of Divines' (1643) the great majority of the ministers were Presbyterians. But the more advanced Puritans, who were predominant in the army and the parliament, ultimately triumphed in the person of Cromwell (q.v.). The Restoration (1660) brought back Episcopacy, and the Act of Uniformity (1662) threw the Puritans of the church into the position of dissenters. Their subsequent history is treated under the different forms of dissent. Before the Civil War broke out so great were the hardships to which the Puritans were exposed that many of them emigrated to America, to seek liberty and peace on the solitary shores of the New World. There they became the founders of the New England states, and cultivated unmolested that form of Christianity to which they were attached. Nowhere did the spirit of Puritanism in its evil as well as its good more thoroughly express itself than in Massachusetts. In Scotland Puritanism dates rather from the 'Second Reformation' of 1638 than from the original establishment of Presbyterianism after the Reformation.

See Neal's *History of the Puritans* (ed. by Toulmin, 5 vols. 1822); the histories by Stowell (1849; new ed. 1878) and Marsden (1850); Bacon, *The Genesis of the New England Churches* (New York, 1874); Ellis, *Puritan Age in Massachusetts* (Boston, 1888); several of the works cited under S. R. GARDINER; Professor Dowden's *Puritan and Anglican* (1901); the articles in this work on INDEPENDENTS, BROWNE, PRESBYTERIANISM, WESTMINSTER ASSEMBLY, PRYNNE, MARPRELATE, HAMPTON COURT, SMECTYMNUUS; on ELIZABETH, JAMES I., CHARLES I., CROMWELL, MILTON; on LAUD, PARKER, GRINDAL, WHITGIFT; and on the Puritans HOWE, BAXTER, OWEN. In Nichol's edition of the Puritan divines (26 vols. 1861 *et seq.*) other names included are those of Manton, Adams, Goodwin, and Clarkson.

Purkinje's Figure, named after the physiologist J. E. Purkinje (1787–1869), professor at Breslau and at Prague; see EYE, Vol. IV. p. 512.

Purl, a beverage made by warming a pint of ale with a quarter of a pint of milk, and adding sugar and a wine-glassful of gin, rum, or brandy.

Purley. See TOOKE (HORNE).

Purmerend, a town of North Holland, 10 miles N. of Amsterdam; pop. 4980.

Purniah, a town of British India, in the presidency of Bengal, 230 miles NNW. of Calcutta, has a trade in jute. Pop. 16,500.

Purple Colours. Painters in oil and water colours produce various shades of purple by mixing certain red and blue pigments. For work in oil French ultramarine, often called French blue, is mixed with vermilion or some madder red (madder carmine is best), or one of these reds with cobalt blue if a pale purple is wanted. For permanent purples in water-colours the same blues are used; but one of the madder reds, not vermilion, should be mixed with them. A much richer purple than any of the above mixtures will give is produced by Prussian blue and one of the lakes from cochineal—viz. carmine or crimson lake—but it is not permanent. This purple, as well as that obtained by mixing Indian red with indigo, also fugitive, was much used by water-colour painters in past years. Purple madder is the only simple purple pigment available for the artist which is durable, and it is unfortunately costly. All purples are changed to neutral and gray tints by the addition of any yellow pigment. For house-painting moroon lake with a little French blue gives a useful purple; but some of the above mixtures also are occasionally used.

There are several ways of dyeing textile fabrics of a purple colour. The most famous of all ancient dyes was the Tyrian purple, which is said to have been discovered at Tyre many centuries before the Christian era. Among the Romans this colour was exclusively employed for dyeing the imperial robe. It was obtained from shellfish belonging to the genera Murex, Purpura, and Buccinum; at least it has been supposed that it was prepared from one or more species of each of these. The colour was so costly that in the time of Augustus one pound of it sold for what would amount to £36 sterling. About the year 1851 what is believed to be the same or a closely similar purple was obtained from uric acid by a peculiar treatment (see MUREX; DYEING, Vol. IV. p. 139; and PHŒNICIA). Archil (q.v.) seems to have been the only simple purple dye known in the middle ages. Purple of Cassius is a compound of gold and tin used in colouring Glass (q.v.), and in porcelain and enamel painting. It was discovered at Leyden by Andrew Cassius about 1683. A preparation of this colour was formerly used for painting miniatures in water-colour; but for this purpose purple madder, being cheaper, has taken its place.

Purple Emperor (*Apatura iris*), one of the largest of British butterflies, and one of the most richly coloured. The expanse of wings is from 2½ to 3¼ inches. The wings are strong and thick, and

the flight is very vigorous. The male flies especially high, and will perch on lofty trees. The caterpillar is green and feeds on sallow.

Purple Emperor.

Purples. See WHEAT.

Purple Wood, or PURPLE HEART, the heartwood of *Copaifera publiflora* and *C. bracteata*, a very handsome wood of a rich plum colour. The trees producing it are natives of British Guiana, and its chief use in England has been for making ramrods for guns.

Pur'pura, a genus of marine Gasteropods, from some species of which (e.g. *P. patula*), as well as from Murex, the famous Tyrian purple dye was derived. *P. lapillus* (the Dog Whelk) is common on most British coasts, and from it also the dye is procurable. See WHELK.

Purpura, or THE PURPLES, is a malady which is often erroneously placed amongst the diseases of the skin. It is in reality a blood disease, and is characterised by the appearance of small round spots, of a deep purple colour, which are seen first and most abundantly on the legs, and afterwards extend to the arms and trunk. They are accompanied by no local pain, are not effaced by pressure (being due to a drop of blood extravasated beneath the cuticle or in the structure of the skin itself), do not rise above the surrounding surface, and are sometimes intermixed with livid patches resembling bruises; and, before disappearing, both the round spots and the patches undergo the same change of colour which a bruise undergoes. These spots are not peculiar to the skin, but occasionally occur upon internal surfaces and in the tissues of viscera. Passive hæmorrhages from the mucous membranes frequently accompany the external symptoms. There is usually much debility, and often a great tendency to faintness. The duration of the disease varies from a few days to a year or more. Slight cases are devoid of danger, and even the hæmorrhagic cases usually recover, unless the bleeding has been excessive or the blood has been extravasated into a vital organ.

Precisely similar appearances occur in the course of other diseases, especially scurvy, severe anæmia, scarlet fever, and smallpox. But the name purpura should be restricted to the cases in which no such disease is discoverable.

The causes of purpura are obscure. The treatment which succeeds best varies in different cases, but the main indication always is to correct the condition of the blood. Arsenic, turpentine, acetate of lead, gallic acid are the drugs which are generally most beneficial; rest in bed, light diet, and laxatives are desirable at the commencement. When there is reason to believe that the disease is dependent upon depressing influences a nutritious diet, tonics, and stimulants are required; but chalybeates should be avoided. If the hæmorrhage proceeds from accessible parts, local measures, such as the employment of ice or strong astringents, should also be had recourse to.

Purser, the name formerly given to the officer in the navy who had the charge and issue of the provisions, slops, soap, tobacco, &c., and who also kept the ship's books; the title was one of the oldest in the service, but the holders of it for long only ranked as warrant-officers, and their duties and responsibilities were in many respects very ill-defined. In the old war-days they were looked upon with great dislike by the seamen, as they were credited with enriching themselves at the expense of the men, and unquestionably the opportunities for sharp practice in their duties were considerable, as also for making money by methods which were not always legitimate; much of this, however, was due to the laxity of the system of victualling and of keeping the ship's accounts in those days. In 1844 this branch of the service was completely reorganised, paymaster being substituted for the title purser; and the officers composing it are now drawn from a much higher class than formerly, coming generally from the same station in life as the combatant officers. See PAYMASTERS.

Purslane (*Portulaca*), a genus of plants of the natural order Portulaceæ, having a bifid calyx, four or six petals, eight or sixteen stamens, and a capsule dividing around the middle. Common Purslane (*P. oleracea*) grows in cultivated and waste grounds on the seashore in almost all tropical and subtropical parts of the world. It is cultivated as a pot-herb. It is a short-lived annual, with spreading and rather procumbent stems, and obovate fleshy leaves, which, as well as the young shoots, are frequently used in salads. The young and tender shoots are pickled in France like gherkins. Purslane is not so common in British gardens as it once was. Some species of Portulaca, such as *P. grandiflora*, of which there are several brilliant varieties, and *P. gillicsii*, are choice half-hardy annuals occasionally cultivated in British gardens. They are reared in hotbeds in spring and planted out in the flower-garden in the end of May, or they are grown in pots exclusively for the purpose of decorating the greenhouse.

Pursuivant. See HERALD.

Pus is a well-known product of inflammation, and occurs as a thick yellow creamy fluid, differing from all other morbid exudations in containing a large number of corpuscles, having a soft and fatty feeling when rubbed between the fingers, a peculiar odour, usually an alkaline reaction, and a specific gravity of about 1·032. Like the blood, it consists of certain definite microscopic elements, and of an intercellular fluid or serum in which they swim.

Of microscopic elements we have (1) the pus-corpuscles, which, both in their microscopical and chemical relations, seem to be identical with the lymph-corpuscles, or colourless blood-cells; in diameter they range from ·004 to ·005 of a line, and each corpuscle consists of a cell-wall, which often appears granular, of viscid transparent contents, and of one or more nuclei, which can be rendered much more apparent by the addition of acetic acid. The other elements are (2) molecular granules and (3) fat-globules. The serum of pus is perfectly clear, of a slightly yellow colour, closely resembling blood-serum, and coagulates on heating into a thick white mass.

The chemical constituents of pus are water (varying from 769 to 907 in 1000 parts), albumen (from 44 to 180), fats (from 9 to 25), extractive matter (from 19 to 29), and inorganic salts (from 6 to 13), in addition to which mucin, pyin, glycin, urea, &c. are occasionally present. Of the inorganic or mineral constituents the soluble salts are to the insoluble in the ratio of 8 to 1, and the chloride of sodium (the chief of the soluble salts) is three times as abundant as in the serum of the blood. The mode of formation of pus is described in the article SUPPURATION.

Pusey, EDWARD BOUVERIE, was born in the year 1800 at Pusey in Berkshire. He was descended from a family of Flemish refugees; his father was

the youngest son of the first Viscount Folkestone, and had assumed the name of Pusey when the estates in Berkshire were bequeathed to him by the last representatives of the Pusey family. He was educated at Eton and Christ Church, Oxford, and was elected a Fellow of Oriel College in 1823. As soon as he had completed his studies at Oxford he passed to Germany, partly to study German, which was in the Oxford of those days practically an unknown tongue, partly to study oriental languages, and partly to become acquainted with the latest forms of German theological teaching. In 1827 he returned to England, and in the following year the Duke of Wellington appointed him regius professor of Hebrew at Oxford, a position which he retained until his death. Although his fame in other respects has caused his Hebrew lecturing to be forgotten, he laboured most unweariedly in the duties of his chair, and attracted a great number of pupils. His first work was an essay in which he sketched the causes that contributed to the Rationalistic character of recent German theology. He acknowledges his indebtedness to Professor Tholuck for some portions of this essay, but the elaborate proof of his position was his own work executed with characteristic thoroughness. It was severely commented on as leaning very decidedly in the direction of the Rationalistic teaching with which it dealt: the charge was greatly exaggerated, besides being caused in part by vagueness of expression throughout the volume. His main position was unassailable: German Rationalism he maintained was the consequence of the spiritual deadness of the orthodox Lutheranism of the day. He was misunderstood as if he had attacked the creed of the Lutherans in its orthodox portions: as a matter of fact he only wished to attribute Rationalism to the want of life in the Lutheran body. But many of his statements were in later years very unsatisfactory to himself, and he withdrew the work from circulation. The whole aim of his life was to prevent the spread in England of Rationalism such as that with which he had become familiar in Germany. Hence, when in 1833 John Henry Newman with the same object began the issue of the *Tracts for the Times*, Pusey very soon joined him; and they, with Keble, were the leaders of this eventful effort. Their object was not to attack the statements of Rationalistic teachers; there was as yet no call for that in England; but they desired to stir up in the Church of England a spiritual vitality and power which would be of itself the best preservative against the infection of the Rationalistic spirit. For this purpose they attempted not to reform, but to restore; they appealed to the idea of the church, to its divine institution, to its services, to its sacraments, to its formulas of faith, to its history, and to the examples of the holiest lives in former generations. They endeavoured to make the church live again before the eyes and minds of men as it had lived in times past. In this connection Pusey wrote his contributions to the *Tracts for the Times*, especially those on Baptism and the Holy Eucharist. His sermons also were vigorous appeals to live the Christian life, and careful expositions of the doctrines which the church from the first had taught. With a similar purpose also in 1836 he commenced the translation of the writings of the ancient fathers of the Christian church under the title of the *Oxford Library of the Fathers*. Dr Pusey's chief contributions to it were a translation of St Augustine's Confessions and of several of the works of Tertullian. The result of these efforts—to which, with the exception of his professorial duties, Dr Pusey entirely devoted himself—was most conspicuous, and extended far beyond the ranks of those who were called by their opponents either Newmanites or Puseyites. But the work was checked by the action of the authorities at Oxford. First Newman's celebrated Tract 90 was condemned in 1841, and in 1843 Pusey was suspended for three years from his office of preaching in Oxford. The occasion of this suspension was a sermon on the Holy Eucharist which he preached before the University, and which a board of six doctors of divinity, without allowing Pusey a hearing, or specifying the points on which he was supposed to be in the wrong, pronounced to be contrary to the teaching of the Church of England. As soon as an opportunity offered Pusey reiterated his teaching, and this time he was unmolested. But before his suspension was over Newman had joined the Roman Catholic communion, and with him went several of his leading disciples. All rumours pointed to the certainty of Pusey soon following; but those who knew him best were assured that never for one moment did he entertain any thought of leaving the Church of England. With Keble he at once set himself to reassure those who were reeling under the blow of Newman's departure; and it was mainly the moral weight of Pusey's work and character which prevented the powerful efforts of Newman between 1833 and 1841 from resulting in a catastrophe greater than any which the English Church has ever experienced. Pusey's unfailing loyalty to the church and deep conviction of God's presence with it, his buoyant hopefulness even in the darkest days, and his great patience cheered and settled many anxious hearts, and stopped others who were on the point of following Newman. His attitude would have had a yet wider result, except for the sad events which followed in rapid succession in the ten years subsequent to Newman's secession. The new power which a civil court had acquired over doctrinal suits—which was exhibited in the judgment in the Gorham case—the constant attacks of bishops and others upon the Oxford movement, the practical inhibition of Pusey from all ministerial work in the diocese of Oxford by Bishop Wilberforce, whereby it was made to appear that the church disowned his teaching—these and other less important but significant events caused the departure to the Roman Church of another band of distinguished men, including Archdeacon (Cardinal) Manning and Archdeacon Wilberforce. But still Pusey laboured on, carefully defining the exact position of the English Church, as against Roman claims on the one hand and against Zwinglianism and Erastianism on the other.

Only the chief of his numerous writings during this period can be alluded to. They included a lengthy letter on the practice of confession, *The Church of England leaves her children free to whom to open their griefs* (1850), a treatise the form of which makes it appear to belong to a moment of controversy, although the matter is really of permanent value; a general defence of his own position in *A Letter to the Bishop of London* in 1851; a work on *The Royal Supremacy not an arbitrary authority, but limited by the laws of the Church of which Kings are members*, in 1850; a larger book on *The Doctrine of the Real Presence*, as contained in the Fathers (1855), and as taught in the Church of England (1857). In this class of writings may be included also Dr Pusey's *Eirenicon* (part i. in 1865, ii. in 1869, iii. in 1870). The object of these volumes was to clear the way for reunion between the Church of England and the Church of Rome on the basis of Catholic, as distinct from Roman Catholic, doctrine and practice.

The reform of Oxford University, which was undertaken after the report of the first Royal Commission on the Universities, and which destroyed for ever the integrity of the originally most intimate bond between the University and

the Church, greatly occupied Pusey's mind. His evidence before the commission, his remarkable pamphlet on the comparative advantages of *Collegiate and Professorial Teaching and Discipline*, and his assiduous work on the Hebdomadal Council for many years are proofs of the interest that he took in the welfare of his university, and of the importance that he attached to a close connection between education and religion.

From 1860 onwards the tide had turned. The teaching for which the Tractarians had laboured and suffered was at that time beginning to be recognised, and those disciples of the Oxford movement who had survived the shock of the events of the last twenty years were spreading its principles throughout the country. But the fruits of the intolerance and persecution of which Oxford had been the scene were also ripening in the form of the spread of religious indifference, based on Rationalistic views of revelation. This was the enemy which from the first Pusey had dreaded. He had at least the satisfaction of knowing that, as a result of the movement in which he had taken so prominent a part, the inner life of the English Church was far better able to bear the onset of such a foe, and to estimate the moral and spiritual ravages which it would make, than was the Lutheran body of the 18th century, or even the Church of England in 1830. Against such teaching he contended for the rest of his life. All his later sermons before the university and most of his later books deal with it. It was with this purpose that he prosecuted Professor Jowett for his statements in his commentary on St Paul's Epistles, and that he took so prominent a part in the later controversy about the Athanasian Creed. His chief works in this connection are the *Lectures on the Book of Daniel*, and *What is of Faith as to Everlasting Punishment?* The former, delivered in 1863, vigorously attack those writers who would assign to the Book of Daniel a date as late as the 2d century B.C. Apart from the marks which the lectures bear of the heated controversy of the time when they were delivered, they are a monument of the author's intellectual power, wide reading, and solid learning. The other book is against the denial of everlasting punishment: its sobriety and fullness, the familiarity which it shows with all the issues raised in the controversy, its deep religious feeling, its calm and calming tone make it one of the most remarkable of Pusey's works. Of a kindred character, although in a different field, are the last two university sermons which he wrote—on the relation of science to faith and on the nature of prophecy.

Two other works must be noticed. Pusey inherited from his predecessor in the Hebrew chair the task of completing *A Catalogue of the Arabic Manuscripts in the Bodleian Library* (1835). It was a most toilsome duty, and occupied his time for six years. Pusey's *Commentary on the Minor Prophets* (1860–77) was his contribution to a commentary on the whole Bible which he had in his mind for many years, and on which he enlisted the labours of Keble and many others. Pusey alone completed his task; death, advancing years, or the claims of other duties prevented the others from contributing their share.

In private life Pusey was a man of warm affection, and widely known for his gentleness, sincerity, and humility. He rarely went into society in early life; at first he withdrew from it for purposes of study and to save more money to give to the poor, but from the time of his wife's death in 1839 he avoided all social amusements. But he was always accessible to any one who wished his advice on religious questions; in fact, he was constantly sought as a spiritual guide by persons of every station. His charity was bounded only by his income; besides abundant gifts to poor people, he spent large sums of money in helping to provide churches in East London, in building St Saviour's, Leeds, and in founding and supporting sisterhoods. His capacity for study and for literary work was immense. He worked only at what it was his duty to study, but within that line he spared neither time nor pains in thoroughly mastering every detail. His power of keeping his main object before his mind without being confused by its details, and of grouping the details in their due position, can be seen in almost any of his works. Opponents of all schools gave him the credit of being confused; but an occasional confusion in his manner of expressing his thoughts did not prevent him from knowing his own mind with singular clearness. He died on 16th September 1882.

The Life of Pusey by Canon Liddon, left unfinished at his death, was completed by the present writer and the Rev. R. J. Wilson, the Canon's literary executors (5 vols. 1893–99).

Pushkin, Alexander Sergeievich, was born at Moscow, 26th May 1799, and educated at Tsarskoe Selo. In 1817 he entered the service of the government, but on account of his liberal opinions was for some time transferred to Bessarabia. In 1820 he published a romantic poem, *Ruslan and Liudmila*. Next came his *Prisoner of the Caucasus* (1822), his *Fountain of Bakhchiserai* (1826), *Tzigani* ('The Gypsies,' 1827), and *Eugene Onegin* (1828; Eng. trans. 1881), a clever novel in verse somewhat after the style of Byron's *Beppo*. In 1829 he published *Poltava*, which has Mazeppa for its hero. About the same time he wrote his fine tragedy *Boris Godunov*. Besides these works of considerable length, he was the author of many graceful lyrical poems, deservedly popular throughout Russia. He also left some prose writings, consisting of a *History of the Revolt of Pugachev* (in the reign of Catharine), several tales, and miscellaneous essays. He was appointed Russian historiographer with a pension of 6000 roubles. He was mortally wounded in a duel, and expired at St Petersburg, January 29 (February 10) 1837. Pushkin is considered the greatest poet whom Russia has yet produced. His writings show versatility, a powerful imagination with vigour of expression. In his *Eugene Onegin*, a Don-Juanesque poem, he is both humorous and pathetic, and many of his smaller pieces display wonderful elegance and finish.

The last-named poem was translated into English verse by Spalding (1881); the *Daughter of the Commandant* was translated in 1891; and a translation of the *Poems*, with introduction and notes by Ivan Panin, appeared at New York in 1889. Pushkin's name is also spelt Poushkin and Pouchekin. See the section on the literature under Russia, and works there cited.

Pushtu, or Pukhtu, the language of the Afghans proper (see Afghanistan), is, according to Darmesteter, not intermediate between the Iranic and Indic branches of the Aryan stock, but is directly derived from the Zend, with Persian, Hindustani, and Arabic admixture. See Trumpp's *Pashtô Grammar* (1873), Strangford's *Letters and Papers* (1878), and Darmesteter's *Chants Populaires des Afghans* (1890).

Pustule, a circumscribed elevation of the cuticle, containing pus: in fact, a small abscess in the skin. Pustules occur in many skin diseases—eczema, acne, scabies, ecthyma, boils, &c.; also very prominently in smallpox. For Malignant Pustule, see Anthrax.

Puteaux, a town 2 miles from the western boundary of Paris, on the left bank of the Seine,

opposite to the Bois de Boulogne. Many Parisians have fine villas here. There are manufactures of dyestuffs and chemicals, dyeing, and calico-printing. Pop. 15,106.

Pute'oli. See POZZUOLI.

Putnam, a town of Connecticut, on the Quinnebang River, 56 miles by rail ENE. of Hartford, with a number of cotton-factories and woollen-mills. Pop. (1890) 6511.

Putnam, ISRAEL, a general of the American Revolution, was born in what is now Danvers, Massachusetts, 7th January 1718. In 1739 he bought a farm between Pomfret and Brooklyn, Connecticut, and for many years devoted himself to its cultivation, gaining meanwhile a high reputation for courage by such personal exploits as following a she-wolf into her lair and killing her single-handed. In 1755 he left as a captain in a contingent of 1000 men which Connecticut sent to repel a threatened French invasion of New York, and was present at the battle of Lake George. In 1758 he was captured by the savages, tortured, and then bound to a tree, and was about to be burned to death when a French officer scattered the firebrands and rescued him. In 1759 he received a regiment, in 1762 he went on the dreadful West India campaign which resulted in the capture of Havanna, and in 1764 he helped to relieve Detroit, then besieged by Pontiac (q.v.). Ten years of quiet at home succeeded, during which he made his farmhouse into an inn, and was conspicuous among the 'Sons of Liberty.' In 1775, after Concord, he was given the command of the forces of Connecticut, and was ranking officer on the day of Bunker Hill, though not in actual command at either the redoubt or the rail-fence. He was next appointed by congress one of the four major-generals, and held the command at New York and in August 1776 at Brooklyn Heights, where he was defeated by General Howe on the 27th. He afterwards held various commands, and in 1777 was appointed to the defence of the Highlands of the Hudson. While at Peekskill a lieutenant in a loyalist regiment was captured as a spy and condemned to death; and, on Sir Henry Clinton's sending a flag of truce threatening vengeance if the sentence should be carried out, Putnam wrote a brief and characteristic reply: 'Headquarters, 7th August 1777.—Edmund Palmer, an officer in the enemy's service, was taken as a spy lurking within our lines; he has been tried as a spy, condemned as a spy, and shall be executed as a spy, and the flag is ordered to depart immediately.—Israel Putnam.—P.S.—He has accordingly been executed.' In 1778, in western Connecticut, Putnam made his famous escape from Governor Tryon's dragoons by riding down the stone steps at Horseneck. The next year he had a stroke of paralysis, and the rest of his life was spent at home. He died 19th May 1790. See Life by Increase N. Tarbox (1876), and article by Professor John Fiske in Appleton's *Cyclopædia of Amer. Biog.* (1888).

His cousin, RUFUS PUTNAM, born 9th April 1738, served against the French from 1757 to 1760, and then settled as a farmer and millwright. On the outbreak of the war he received a lieutenant-colonel's commission, and rendered good service as an engineer. In 1778 he helped his cousin to fortify West Point. Afterwards he commanded a regiment till the end of the war, and in 1783 he was promoted to brigadier-general. In 1788 he founded Marietta, Ohio; in 1789 he was appointed a judge of the supreme court of the North-west Territory; and from 1793 to 1803 he was surveyor-general of the United States. He died in Marietta, 1st May 1824.—Israel's grand-nephew, GEORGE PALMER PUTNAM, born in Brunswick, Maine, 7th February 1814, in 1840 became partner in the book-firm of Wiley & Putnam, New York, established a branch in London in 1841, and in 1848 returned to the United States and started business alone. In 1852 he founded *Putnam's Magazine.* In 1863 he retired from business, but in 1866 he established the firm of G. P. Putnam & Sons (now G. P. Putnam's Sons). He died 20th December 1872. He wrote and compiled several books, and was the author of the first *Plea for International Copyright* (1837) printed in America.

Putney, a suburb of London, in Surrey, 6 miles WSW. of Waterloo, on the south side of the tidal Thames, which, here nearly 300 yards broad, is crossed by a new granite bridge (1884–86), leading to Fulham, and founded and opened by the Prince of Wales. It is a great rowing place, the starting-point of the Oxford and Cambridge boat-race; and from its ready access to Town, the river, Putney Heath, and Wimbledon Common, has grown rapidly of recent years, its principal feature that there are no poor. The parish church, with a 15th-century tower and the chantry of Bishop West of Ely, was mainly rebuilt in 1836; in the churchyard is Toland's grave. Putney is the birthplace of Thomas Cromwell and Gibbon, the residence of Mr Theodore Watts and Mr Swinburne, and the deathplace of Pitt and Leigh Hunt. From Putney's old bridge Mary Wollstonecraft tried to drown herself; and on Putney Heath Pitt fought his duel with Tierney (1798), Castlereagh his with Canning (1809). Pop. (1851) 5280; (1881) 13,235; (1891) 17,771.

Putrefaction is the term given to the decomposition of organic substances when accompanied by an offensive smell. It was long supposed to be ordinary chemical change due to the complexity, resulting instability, and affinity for oxygen of organic matter. It is now known to be the result of the living activity of certain minute plants called Bacteria (q.v.), which also cause Fermentation (q.v.) and many diseases (see GERM). The spores of these plants are present in great numbers in the lower levels of the air, in water, and on the surface of the earth; and, as they are only about ·001 mm. in diameter and two to four times as long, it is not surprising that they were not seen, and that putrefaction was supposed to be spontaneous. But, if we boil an infusion of organic stuff and so kill the bacteria in it, and, while the steam is coming freely off, close it up with a plug of cotton wool, which, while allowing free access to air, prevents any germs or spores from reaching the fluid, it will remain without any change for years, but will begin to putrefy in a day or two if the plug be removed. A low temperature, although it will not kill the bacteria, will stop their growth and the resulting destructive changes; hence the use of freezing food on shipboard. Salicylic, carbolic, and other acids also check growth, but there seem to be only a few poisons, such as corrosive sublimate, chlorine, and bromine, that actually kill. Drying stops growth and kills the developed plant in a few days, but the spores will live for a long time in a dried condition. The effect of oxygen is various: some species require it, while others are hindered in their growth by it; and a high pressure of oxygen will kill even those kinds that need a certain amount in a few days. Of the precise chemical changes that take place as a result of the life of bacteria we are still largely ignorant; the chief final results of these changes are described under FERMENTATION. For an investigation in the causes of putrefaction, see Tyndall's *Floating Matter of the Air* (1881).

Putrid Fever. See JAIL FEVER.

Putty, a composition of *whiting* and *drying* oil worked into a thick paste, used by painters and glaziers, which in time becomes very hard.

Putty-powder is the binoxide or dioxide of tin, SnO_2. It is prepared from the scum or crude oxide which forms on the surface of melted tin, which is removed and purified by calcination, and then ground to powder. Putty-powder is used for polishing stone and glass, for making white enamel, and for giving glass an opaque colour.

Putumayo, or Içá, a tributary of the Amazon, rises in Colombia, and flows SE. for 950 miles.

Puvis de Chavannes, Pierre, a painter of marked individuality, sometimes said to belong to the 'decorative school,' was born at Lyons, 14th December 1824. See a work by Vachon (1895).

Puy, Le, or Le Puy-en-Velay, a town of France (dept. Haute-Loire), 70 miles SW. of Lyons by rail, consists of the new town in a valley and the old town, this latter one of the most picturesque in France. Puy (Berry, *pui* or *peu*, 'a hill;' Ital. *poggio;* Lat. *podium;* Gr. *podion*) is the name commonly given in the highlands of Auvergne and the Cevennes to the truncated conical peaks of extinct volcanoes. The town of Le Puy stands on the steep slopes of Mount Anis (2050 feet), from the summit of which starts up precipitously the basaltic mass called Mont Corneille, crowned by a colossal figure (53 feet) of the Virgin, made of Russian cannon brought from Sebastopol. The most notable building is the Romanesque cathedral (6th–12th century), with a venerated image of the Virgin and ancient cloisters; it is situated in the highest part of the town. There are other ancient and interesting churches and a museum. Lace and thread work are manufactured. Pop. (1872) 18,961; (1891) 20,038.

Puya, the largest of the Bromeliaceæ (q.v.), found in Chili as far south as 40° S. It equals the Agave (which in its characters it somewhat resembles) in height, and greatly surpasses it in the thickness of its half-woody stem. When the plant is mature it thrusts, forth from its crown of spiny leaves a huge panicle of yellow flowers, which may be from 6 to 9 feet in height. The plant has been grown under cover in England, and will thrive in the open air in the Mediterranean regions of Europe.

Puy-de-Dôme, a central department of France, containing an area of 3070 sq. m. and a pop. (1891) of 564,266. The western side of the department is an elevated volcanic region, studded with numerous extinct cones, and greatly broken by corries, erosion valleys, crater lakes, &c. (see France). The highest cones are Puy-de-Sancy (6188 feet) and Puy-de-Dôme (4806); on the east side the Forez Mountains (5380) march with the frontier. The principal rivers are the Allier, a tributary of the Loire, and the Dordogne. The soil is, in general, thin and poor; but its volcanic character fosters vegetation, especially in the valley of Limagne. Agriculture and cattle-breeding are the chief occupations. The climate is uncertain, and severe in the mountains. The principal minerals are coal and lead. Hot and cold mineral springs are abundant, among the most frequented being those of Mont Dore (q.v.), Châteaunenf, St Nectaire, Royat, Châteldon, &c. The department is subdivided into the arrondissements of Ambert, Clermont-Ferrand, Issoire, Riom, and Thiers. Capital, Clermont-Ferrand.

Puzzle-monkey. See Araucaria.

Puzzola'na. See Cements.

Pwllheli, a brisk little seaport and popular watering-place, 22 miles by rail S. by W. of Carnarvon in Wales, with lobster and oyster fisheries. It is a municipal borough, uniting with Carnarvon, &c. to return one member. Pop. of parish, 3232.

Pyæmia (from the Gr. *pyon*, 'pus,' and *haima*, 'blood'), or purulent infection of the blood, is a disease whose exciting cause is the introduction of decomposing pus or wound discharges, or the products of decomposition of animal fluids, into the circulation, through an ulcer or a wound, or an imperfectly closed vein (see Phlebitis and Puerperal Fever). The term *Septicæmia* is applied by some to the same disease, by others only to very grave cases of pyæmia; while by many it is restricted to cases of blood-poisoning by putrid animal matters in general, such as those obtained from decomposing hides or dead bodies, or borne on foul air or septic gases. The two conditions have a general resemblance to each other. The poison is rapidly absorbed and diffused, and the blood undergoes certain changes, the nature of which chemistry has as yet failed to detect; it is certain, however, that the blood contains micro-organisms (micrococci and bacteria; see Germ). Within twenty-four hours, in very acute cases, there are severe shiverings, headache, and giddiness followed by heat, perspiration, and accelerated circulation. In twenty-four hours more the patient may be in a hopeless condition, delirious, and rapidly sinking. In less acute cases the symptoms closely resemble those of typhoid fever, and in this form the disease is a common cause of death after surgical operations; such cases are invariably characterised by the formation of secondary abscesses in the lungs, liver, kidneys, and other internal organs, in the various glands (the parotid gland in President Garfield's case), in the joints, and in the tissues immediately under the skin. The pus of such abscesses always contains bacteria. There is usually more or less delirium. The patient generally dies of exhaustion. Recovery is rare. It is chiefly, however, in the presence of *predisposing causes*, such as previous illness, prostration from organic disease or surgical complaints, or from difficult parturition, unhealthy occupations, &c., that the poison acts so severely; these, with the occurrence of putrefaction in a wound, may convert a comparatively slight local mischief into infection of the whole mass of the blood.

Bearing in mind the manner in which pyæmia originates, it is clear that this disease is one to be prevented rather than cured. Until comparatively recently, when it was acknowledged that pyæmia was the cause of death in 10 per cent. of *all* cases of amputation, and of 43 per cent. of *all fatal* primary amputations, the careful preparation of a patient before operation was, with justice, most strenuously insisted on. 'Patients must be strengthened,' said Mr Callender, 'by tonics, such as quinine and iron; and their secretions must be set right by appropriate alteratives; this treatment must be continued for a considerable period.' Diet should be attended to, and intemperate patients 'should be accustomed to a more healthy mode of life.' After operation, also, patients should be adequately supported with nutritious diet, and with stimulants and opium if necessary. No judicious surgeon will ever neglect such measures. But the really essential matter in the prevention of pyæmia is the prevention of putrefaction in the wound discharges. This was clearly proved by the results achieved by Sir Joseph (afterwards Lord) Lister and other surgeons at home and abroad, who have adopted the antiseptic method of treating wounds (see Antiseptic Surgery). For several years Lister's wards in Glasgow Royal Infirmary, formerly ravaged by pyæmia, remained free of the disease after the adoption of the antiseptic system; after two years' practice of this treatment purulent infection disappeared from the wards of the hospital

at Lyons, where it formerly had a permanent home; and similar testimony might be quoted from every quarter and to any extent. The use of antiseptics, adopted early and followed out intelligently, may be said to have abolished the risk of purulent infection in wounds from operation or injury.

Even when the disease has shown itself, the use of antiseptics (perchloride and other salts of mercury, carbolic acid, boracic acid, boroglyceride, iodoform, thymol, eucalyptol, &c.) should be resorted to locally. The bowels, skin, and kidneys may be acted on by suitable purgatives, diaphoretics, and diuretics, with a view to the elimination of the poison; but the patient must be carefully watched for signs of depression, which must be combated with opium and stimulants, both of which should be given in small and frequently repeated doses. Quinine in moderately large doses is very serviceable throughout the whole course of such a case; larger doses may occasionally be given to reduce excessively high temperatures, though antipyretics in general must be used with extreme caution. Various antiseptic drugs have been recommended for internal use, such as salicylic acid and the salicylates, the hyposulphite of sodium, and the hyposulphites generally. This treatment, combined with the most assiduous nursing and generous dieting, and the appropriate surgical management of such secondary abscesses as form, will sometimes prove successful.

Pyat, Felix, a French journalist and communist, born at Vierzon (dept. Cher), on 4th October 1810, studied law and in 1831 was admitted to the bar, but chiefly wrote articles, feuilletons, and plays, often with strong political allusions. He signed Ledru-Rollin's appeal to the masses to arm in 1849, and, the attempt having failed, escaped to Switzerland. After that he found refuge in Belgium and England, and was a member of the 'European revolutionary committee.' Returning to France on amnesty in 1870, he made himself a leader of the Paris communists and took a foremost part in the destruction of the Vendome Column; on the fall of the Commune he escaped to London. He was tried and condemned to death, in absence, in 1873, for his share in the misdeeds of the Communal Government, but was pardoned in 1880. Marseilles chose him one of her deputies in 1888. He died 5th August 1889 at St Gratien.

Pycnogonidæ, a very remarkable group of Arthropod animals, perhaps intermediate between Crustaceans and Arachnids. The body consists of a fused cephalothoracic region, three free thoracic segments, and a rudimentary abdomen. The head usually bears a tubular proboscis, a pair of mandibles, a pair of slender palps, and a pair of egg-carrying legs; but mandibles and palps may be absent, and the egg-carrying legs are sometimes restricted to the males. Besides these there are four pairs of clawed limbs, into which prolongations of the gut extend. There is a dorsal heart; respiration is effected through the skin. The males usually carry the eggs. There is a metamorphosis in development. The pycnogonidæ are sometimes called 'sea-spiders' and also Pantopoda. They are all marine, and some of them live among algæ, or are to be found under stones on the beach, whilst others are dredged from deep water. They seem to feed by sucking other animals. See Hoek, *Challenger* Report (iii. 1880); and Dohrn, *Fauna d. Golfes v. Neapel* (iv. 1881).

Pycnogonum littorale.

Pye, Henry James, poet-laureate, was born in London, 10th July 1745, and educated at Magdalen College, Oxford, in 1772 being made a D.C.L. He held a commission in the Berkshire militia, in 1784 was elected member for that county, in 1790 succeeded Warton as laureate, and in 1792 was appointed a London police magistrate. He died at Pinner, near Harrow, 13th August 1813. The works of 'poetical Pye' (in Scott's phrase), who, as the editor of Byron's *Vision of Judgment* remarked, was 'eminently respectable in everything but his poetry,' are nearly twenty in number, and include *Alfred* (1801), besides birthday and new-year odes.

Pygmalion, grandson of the king of Cyprus, in love with an ivory statue of a maiden he had made, prayed to Aphrodite to give it life; and, his prayer being granted, married the maiden. There is no classical authority for calling her Galatea. In his *Pygmalion and Galatea* W. S. Gilbert followed a German play.

Pygmies. See Dwarf; Quatrefages, *Les Pygmées* (1887); and for the two types of pygmies whom Stanley saw in the Central African forest, see *In Darkest Africa* (1890), and Burrows, *In the Land of the Pigmies* (1889).

Pylades. See Orestes.

Pym, John, was born of a good old Somersetshire stock at Brymore, near Bridgwater, in 1584. He entered Broadgates Hall (now Pembroke College), Oxford, in 1599, as a gentleman-commoner, but left in 1602 without taking a degree, and then probably studied law at one of the Inns of Court. He married in 1614, but in 1620 was left a widower with five young children, and next year was first returned to parliament by Calne. This seat he exchanged in 1625 for Tavistock. He at once attached himself to the Country party, and proceeded to war against monopolies, papistry, the Spanish match, and absolutism with a vigour that brought him three months' durance. He was one of the members who presented a petition to James I. at Newmarket, when 'Chairs!' cried the king, 'chairs! here be twal kynges comin'!' and in 1626, the year after the accession of Charles I., he took a prominent part in the impeachment of the Duke of Buckingham. In the parliament of 1628 he stood second only to Sir John Eliot, whom he ably supported in the debate on the Petition of Right, but whom he opposed in the matter of tonnage and poundage, deeming the privileges of parliament inferior to the liberties of the kingdom. In the Short Parliament (1640), when, in Clarendon's words, 'men gazed on each other, looking who should begin, much the greater part having never sat before,' Pym on 17th April 'brake the ice by a two hours' discourse, in which he summed up shortly and sharply all that most reflected upon the prudence and justice of the government, that they might see how much work they had to do to satisfy their country.' And lastly, in the Long Parliament, having meanwhile joined hands with the Scots, and ridden with Hampden through England, urging the voters to their duty, Pym on 11th November named Strafford, twelve years earlier his friend and ally, as the 'principal author and promoter of all those counsels which had exposed the kingdom to so much ruin.' In the impeachment of Strafford which followed, resulting in his execution under a bill of attainder, Pym took the leading part; and Pym's is the chief credit of this masterstroke of policy, which deprived the king of the one man of resolute temper and powerful genius who supported his cause. In the proceedings against Laud Pym was also conspicuous, as in the carrying of the Grand Remonstrance and in every other crisis of moment up to the time when war became inevitable; he was the one of the 'Five

Members' whom Charles singled out by name. On the breaking out of hostilities he remained at his post in London, and there, in the exercise of the functions of the executive, rendered services to the cause not less valuable and essential than those of a general in the field. While the strife was yet pending he died, through the breaking of an internal abscess, at Derby House on 8th December 1643, having only the month before been appointed to the important post of Lieutenant of the Ordnance. 'King Pym' was buried in Westminster Abbey with great pomp and magnificence, but at the Restoration his remains were cast out into a pit in St Margaret's churchyard.

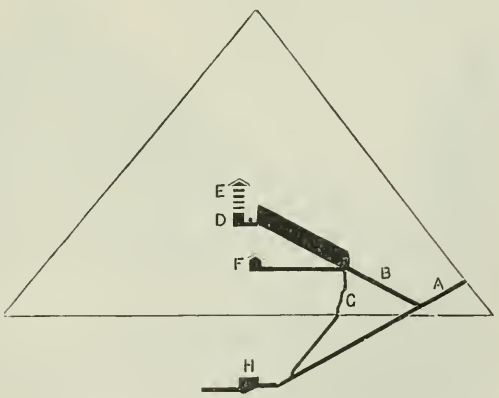
'The most popular man,' says Clarendon, 'and the most able to do hurt that hath lived in any time.' And such Pym was, only emphasis ought to be laid upon the 'able.' He was no demagogue, no revolutionist, as neither was he a narrow precisian. His intellect, on the contrary, was 'intensely conservative,' in Mr Gardiner's phrase; he was a champion of what he believed to be the ancient constitution against those who he thought were striving to subvert it. He was, moreover, an English country gentleman, who liked the good things of this life, and was not so circumspect in his conduct but what scandal made free with his name, asserting, for instance, that 'Master Pym had succeeded the Earl of Strafford in the affections of my lady Carlisle.'

See John Forster's *Eminent British Statesmen* (vol. iii. 1837); Goldwin Smith's *Three English Statesmen* (1867); and other works cited at CHARLES I., ELIOT (SIR JOHN), and STRAFFORD.

Pyracantha. See CRATÆGUS.

Pyramid, in Geometry, is a solid figure, of which the base is a plane rectilinear figure, and the sides are triangles, converging to a point at the top or 'apex.' Pyramids, like prisms, are named from the form of their bases: thus, a pyramid having a triangle for its base is a triangular pyramid, with a square base, a square pyramid, with any four-sided figure for its base, a quadrangular pyramid; or it may be pentagonal, hexagonal, &c. Pyramids may be either 'right' or 'oblique' (see PRISM). A right pyramid, with an equilateral figure for its base, has all its sloping edges equal; but this is not the case if the pyramid be oblique. The most remarkable property of the pyramid is that its volume is exactly one-third of that of a prism having the same base and vertical height; and it follows from this that all pyramids having the same base and height are equal to one another. The word (Gr. *pyramis*) is of Egyptian origin.

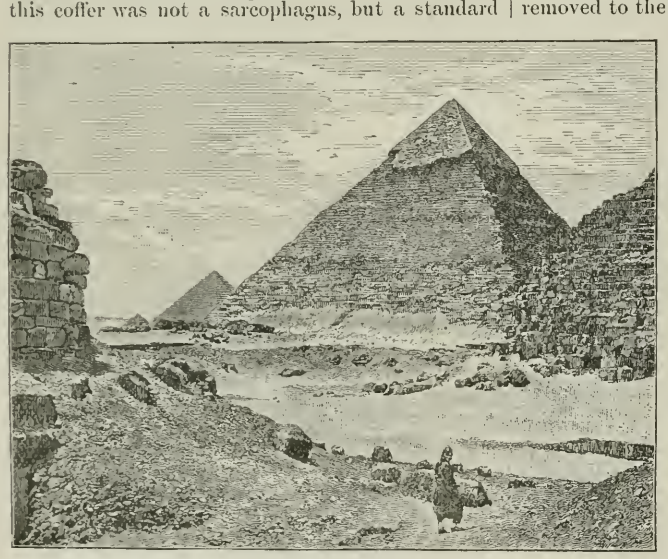
Pyramid, a structure of the shape of the geometric figure so called, erected in different parts of the Old and New World, the most important being the Pyramids of Egypt, which were reckoned among the seven wonders of the world. They are about seventy-five in number, of different sizes, situated chiefly between 29° and 30° N. lat., and are masses of stone (or rarely brick), with square bases and triangular sides. Although various opinions have prevailed as to their use, as that they were erected for astrological, astronomical, and metrological purposes, for resisting the encroachment of the sand of the desert, for granaries, reservoirs, &c., there is no doubt that they were really nothing more than the tombs of monarchs of Egypt who flourished from the first to the twelfth dynasty. With the exception of some very late pyramids in Nubia, none were constructed after the twelfth dynasty; the later kings were buried at Abydos, Thebes, and other places, in tombs of a totally different construction. The pyramids of Egypt may be described as monuments built over the sepulchral chambers of kings. The Egyptian monarch was ever careful to prepare his 'eternal abode.' For this purpose a shaft of the size of the intended sarcophagus was first hollowed in the rock at an incline suitable for lowering the coffin, and at a convenient depth a rectangular chamber was excavated in the solid rock. Over this chamber a cubical mass of masonry of square blocks was then placed, leaving the orifice of the shaft open. Additions continued to be made to this cubical mass both in height and breadth as long as the monarch lived, so that at his death all that remained to be done was to face and smooth the exterior of the step-formed mound by adding courses of long blocks on each layer of the steps, and then cutting the whole to a flat or even surface. This outer masonry or casing has in most instances been stripped off. Provision was made for protecting the vertical joints by placing each stone half-way over another. The masonry is admirably finished; and the mechanical means by which such immense masses of stone were raised to their places must have been powerful and elaborate. The finer stones were quarried at Tura and other places on the opposite bank of the Nile; sometimes, however, granite taken from the quarries of Syene was employed for the casing. The entrances were carefully filled up, and the passage protected by stone portcullises and other contrivances, to prevent ingress to the sepulchral chamber. The sides of the pyramids face the cardinal points, and the entrances face the north. The most remarkable and finest pyramids are those of Gizeh (Giza),



Section of Great Pyramid of Gizeh:
A, B, entrance passages; F, Queen's Chamber; D, King's Chamber; G, well; H, subterranean apartment.

situated on the edge of the Libyan Desert, near Memphis, on the west bank of the Nile. Of the three largest and most famous the First or Great Pyramid was the sepulchre of Chufu, the second king of the fourth dynasty (3733–3666 B.C. according to Brugsch). Chufu is the Cheops of Herodotus, the Chembis or Chemmis of Diodorus, and the Suphis of Manetho. Its height was originally 481 feet, and its base 774 feet square; in other words, it was higher than St Paul's Cathedral, on an area about the size of Lincoln's Inn Fields. Its slope or angle was 51° 50′. It has, however, been much despoiled and stripped of its exterior blocks for the building of the mosques and walls of Cairo. The original sepulchral chamber, 46 feet × 27 feet, and 10 feet 6 inches high, was hewn in the solid rock, and was reached by a passage, 320 feet long, which descended to it from the entrance at the foot of the pyramid. The excavations in this direction were subsequently abandoned, and a second chamber, with a triangular

roof, was constructed in the masonry of the pyramid, 17 feet × 19 feet, and 20 feet high. This was reached by a passage rising at an inclination of 26° 18′, terminating in a horizontal passage. It is called the Queen's Chamber, and occupies a position nearly in the centre of the pyramid. The monument—probably owing to the long life attained by the monarch—still progressing, a third chamber, called the King's, was then constructed by prolonging the ascending passage of the Queen's Chamber for 150 feet further into the very centre of the pyramid, and after a short horizontal passage, making a room 17 × 34 feet, and 19 feet high. To diminish the pressure of the superincumbent masonry on the flat roof five small chambers (E in fig.) were made vertically in succession above the roof, the apex of the pointed uppermost chamber (in which the name of Chufu is scrawled) being rather more than 69 feet above the roof of the King's Chamber. The end of the horizontal passage was carefully finished, and cased with slabs of red syenitic granite exquisitely fitted together; and in the King's Chamber is the broken red granite sarcophagus of King Chufu, 7 feet 6½ inches long, 3 feet 3 inches broad, and 3 feet 5 inches high, to contain which the pyramid was built. Piazzi Smyth fancied (for it is nothing more than fancy) that this coffer was not a sarcophagus, but a standard measure of capacity, of which the British quarter is the fourth part. As the heat of this chamber was stifling, two small air-channels, or chimneys, about eight inches square, were made, ascending to the north and south sides of the pyramid, which perfectly ventilate it. After the mummy was deposited in the King's Chamber, the entrance was closed with granite portcullises, and a well made at the junction of the upward-inclined and horizontal passages, by which the workmen descended into the downward-inclined passage. According to Herodotus, this pyramid took a long time in construction—100,000 men being employed on it for thirty years. The facing-stones were said to be inscribed with writing, probably of a religious character. The Great Pyramid was opened by the 'Abbaside Caliph El Mamûn in the 9th century.



The Second Pyramid.

The Second Pyramid is situated on a higher elevation than the first, and was built by Chafra or Chephren (3666–3633 B.C.), third king of the fourth dynasty. It is 450 feet high, on a base of 700 feet, and has two sepulchral chambers, which were opened by Belzoni in 1816. The masonry is inferior to the first, but it was anciently cased below with polished stones, some of which remain, while the top still retains its original casing.

The Third Pyramid, built by Menkaura, or Mycerinus (3633 B.C.), fourth king of the fourth dynasty, is much smaller than the other two, being only 215 feet high by 350 feet at the base. It has three chambers, the lowest of which, granite lined, held a sarcophagus of whinstone and a wooden coffin. The inscription on the coffin reads: 'Osiris, King of the North and South, Men-Kau-Ra, living for ever! The heavens have produced thee, thou was engendered by Nut (the sky), thou art the offspring of Seb (the earth). Thy mother Nut spreads herself over thee in her form as a divine mystery. She has granted thee to be a god. Thou shalt never more have enemies, O King of the North and South, Men-Kau-Ra, living for ever' (Budge, *The Nile*, 141–142). From this we may conclude that the Egyptian religion and the doctrine of immortality were fixed as early as 3600 B.C. Amongst the débris of the coffin and in the chambers were found the legs and part of the trunk of a body with linen wrapper, supposed by some to be that of the monarch, but by others to be that of an Arab. This body and fragments of the coffin were removed to the British Museum; but the stone sarcophagus was unfortunately lost off Carthagena by the sinking of the vessel in which it was being transported to England. The masonry of this pyramid is most excellent, and it was anciently cased half-way up with granite, the remains of which are still visible. It was wantonly damaged by Saladin's nephew, El-Kâmil, in the 12th century, in the insane desire of destroying it. The Third Pyramid is regarded with superstitious dread by the natives, on account of a supposed lady's ghost, and there is a curious legend connecting it with the courtesan Rhodope.

There are six other pyramids of inferior size and interest at Gîzeh; others at Abou Roâsh, six miles to the north-west of the same spot; and four (originally fourteen) at Abusîr (Busiris), with the names of Sahu-ra and Usr-en-ra of the fifth and sixth dynasties. A group of eleven pyramids remains at Sakkara, some of which were explored in 1880–81 by M. Maspero, such as those of Unas (3333 B.C.), Teta (3266), and Pepi (3233), all of the fifth and sixth dynasties. The so-called Step Pyramid at Sakkara is believed to have been built by Uenephes of the first dynasty. Six pyramids still stand at Dahshûr; and that at Meydûm, with a peculiar construction in three stages, is supposed to be the tomb of Seneferu (3766 B.C.), Chufu's predecessor in the fourth dynasty. There are also pyramids in the Fayyûm, and some small ones of brick at Thebes. In Nubia, the ancient Ethiopia, are several pyramids, the tombs of the monarchs of Meroë from 600 to 100 B.C. and of some of the Ethiopian conquerors of Egypt. They are taller in proportion to their base than the Egyptian pyramids, and generally have a sepulchral hall, or propylon, with sculptures, which faces the east.

In Assyria the Birs Nimrûd, or Tower of Belus, was a kind of step-shaped pyramid of seven different-coloured bricks, dedicated to the planets by Nebuchadnezzar. The Mujelliba, another mound, was of pyramidal shape. The pyramid

also entered into the architecture of the tomb of Sardanapalus at Tarsus, and of the Mausoleum of Artemisia at Halicarnassus. A small pyramid, the sepulchre of C. Cestius, imitated from the Egyptian in the days of Augustus, still exists within the wall of Aurelian at Rome. Temples and other monuments of pyramidal shape are found in India, China, Cambodia, Java, the Polynesian Islands, and elsewhere. The Toltecs and Aztecs erected temples in Mexico, called *Teocalli* (q.v.), or abodes of gods, of pyramidal shape, with steps or terraces by which to ascend and reach an altar, generally placed on the summit, where human sacrifices and other rites were performed. These, however, are not true pyramids, the pure and simple form of which is restricted to Egypt. The pyramidal form entered extensively into the architecture of the Egyptians, and appears on the tops of obelisks and tombs as a kind of roof. Small models of pyramids, with inscribed adorations to the sun, or having royal names, were also placed in the tombs.

See Lepsius, *Ueber den Bau der Pyramiden* (1843); Wilkinson, *Topogr. of Thebes* 1835); Vyse, *Operations carried on at Gizeh in 1837* (1842); W. Flinders Petrie, *The Great Pyramid* (1888). Ingenious fancies about the supposed metrological and astrological purport of the pyramids are given in Piazzi Smyth's *Our Inheritance in the Great Pyramid* (1864), and R. A. Proctor's *The Great Pyramid* (1882). The astronomical data afforded by the orientation of temples and pyramids were in 1891 subjected to thorough investigation by Mr Norman Lockyer.

Pyramids, a game played on a billiard-table. Fifteen red balls are placed on the table in the form of a pyramid, the apex of the pyramid being on the *winning spot*, with the base nearer to the top of the table. There is also a sixteenth white ball, which is used by both players when striking. The object of the players is to hole the pyramid balls. The first stroke is from hand; the succeeding strokes are played from where the white ball stops, unless the striker runs in, when his adversary plays from hand. Also, when only two balls remain on the table, the white and the red are played with alternately. When a player holes a pyramid ball he scores one, and plays again on any ball he likes. If a player runs in or gives a miss, one is deducted from his score, and a red ball is replaced on the table on the winning spot, or as near in a straight line beyond it as it will go without touching another ball; if the player has made no score, he owes one, and the first red ball he holes is placed on the table. When all the red balls are holed, the lower score is deducted from the higher, and the difference is the number of lives won. The game is generally played for so much a life, with a stake on the pool equal to the value of three lives. The lives are not paid for when taken (as at pool), but the difference in the scores is recorded on a slate marking-board at the conclusion of each game.

The principal varieties of pyramids are *shell out* and *snooker*. Shell out is pyramids played by more than two persons. The only differences are that, if a player runs in or misses, one is deducted from his score, but no ball is replaced on the table, and that the last ball scores two. At snooker, in addition to the pyramid balls, some of the pool balls (beginning with the yellow) are placed on various spots on the table. A red pyramid ball must first be played on, and, if it is holed, the striker must then play on a pool ball. The pool balls score two, three, four, five, and six respectively, according to the order of their colours on the marking-board: running in or missing when playing on a pool ball scores correspondingly against, the amount being added to the opponent's score. When a pool ball is holed, it is replaced on its original spot, and the striker must next play on a pyramid ball. When all the pyramid balls have been holed, the pool balls are played on in the order of their colours, but are not then replaced when holed.

A great point is to avoid being *snookered*—i.e. to play on a pyramid ball so that if holed a pool ball is left open, and *vice versâ*. If a player is snookered, his adversary adds to his score the value of the nearest pool ball. Some rules compel the striker to name the ball played at, when, if he fails to hit it, he is snookered off that. The rules of snooker vary much in different rooms.

Pyramus and Thisbe. The tragical history of these two lovers is told by Ovid in the 4th book of his *Metamorphoses*. They were natives of Babylon, and tenderly attached to each other, but, as their parents would not hear of their marriage, they had to content themselves with clandestine interviews by night. On one occasion they arranged to meet at the tomb of Ninus, where Thisbe, who was first at the trysting-spot, was startled to discover a lioness. She immediately ran off, but in her terror and haste dropped her garment, which the fierce animal, that had just torn an ox in pieces, covered with blood. Soon after Pyramus appeared, and, seeing his mistress's robe, came to the conclusion she had been murdered, whereupon he killed himself. Thisbe now returned, and, beholding her lover lying dead on the ground, put an end to her own life. The story was a favourite one during the middle ages. Bottom pronounces it 'a very good piece of work and a merry' in *A Midsummer Night's Dream*.

Pyrenees, the mountain-chain that divides France from Spain, stretches across from the Mediterranean to the south-east corner of the Bay of Biscay, a distance of 270 miles; the breadth of the system varies between 15 and 70 miles, and the area it covers measures 13,000 sq. m. The Pyrenees form a regular and continuous chain, divisible into three portions, the Western, the Central, and the Eastern Pyrenees. The first-named division extends eastwards from the Bay of Biscay to the Port de Canfranc (or Col de Somport), a carriage-road that crosses the chain at an elevation of 5380 feet, and leads from Oloron to Saragossa. This division is the lowest in the entire chain, its average height being 3300 to 4300 feet. Here two passes give access to Spain, that of St Jean Pied de Port (or Roncesvalles) and that between Bayonne and Elizondo; the railway from Bayonne to San Sebastian passes the end of the chain close to the sea. The Central Pyrenees, extending from the Port de Canfranc to the Col de la Perche, this connecting the valley of the French Tet (dept. Pyrénées-Orientales) with the valley of the Spanish Segre (prov. Lerida), contain the highest peaks and the most imposing mountain-masses of the entire system, as Pic de Néthou (in Maladetta), 11,168 feet; Mont Perdu, 10,998; Vignemale, 10,794; Marboré, 10,673; and Pic du Midi, 9466. The summits of the Eastern Pyrenees, which extend eastwards from the Col de la Perche (5300 feet), the second pass over the lofty chain, range between 6500 and 7500 feet (Puigmal, 9545; Canigou, 9138); and, although the altitude decreases as they approach the Mediterranean, they still reach 2100 feet in the Albères close to the sea. This portion is crossed by the old Roman road from Perpignan to Figueras and pierced by the railway tunnel for the line between the same two towns. The frontier between France and Spain coincides generally with the line of highest summits in the main chain: the principal exception is that at Maladetta the frontier strikes north so as to include within the boundaries of Spain the valley of Aran, which geographically belongs to France. On both north and south the mountains sink down to the plains in a series

of terraces, with precipitous faces, the general slope on the Spanish side being somewhat steeper than that on the French side. The valleys cut into the mountain-mass on both sides almost directly at right angles, in the form of deep ravines, and with the regularity of the spines of a fish's backbone. Very many of them terminate in caldron-shaped basins, called *cirques*, or by the native mountaineers *oules* (= pots), the sides of which are precipitous and seamed with waterfalls; the most celebrated is the Cirque of Gavarnie, at the head of Gave de Pau, with a waterfall 1515 feet high. Of the numerous streams that have their origin in the mountains, those on the Spanish side are for the most part feeders of the Ebro, whilst the French streams—generally called *gaves*—feed the Adour, the Garonne, and certain little rivers that reach the Mediterranean. The lower Pyrenean valleys through which these streams flow are in many cases covered with grass or forest, or even vineyards and olive-groves. Snow lies on the highest pinnacles, the snow-line being put at 9200 feet on the south side and at 8300 on the north. A narrow belt of glaciers runs from east to west just below the peaks of the Central Pyrenees, but almost wholly on the French side. Vegetation is most developed in the Western division, where the rainfall is heaviest; but, whilst it is there central European in its characteristics, the vegetation of the Eastern division is subtropical, allied to that of the Mediterranean coasts. The geological nucleus of the range is granite, which comes to the surface in most of the highest peaks. But above the granite lie strata of nearly all subsequent ages, especially Silurian deposits, Cretaceous limestones (hippurite), and limestones (nummulite) of the Eocene period. Minerals are not generally abundant, though iron is worked in the French departments of Basses-Pyrénées and Pyrénées-Orientales; coal exists on the Spanish side and lignite on the French. There are numerous mineral springs (several being hot), those of Eaux-Bonnes, Cauterets, Eaux-Chaudes, Bagnères de Bigorre and de Luchon, and Barèges being the best known. Except the passes already mentioned, the Pyrenees are crossed only by mountain-paths, that none but foot-passengers can use, and they only in the summer; the most remarkable is Roland's Gap (9318 feet), on the west side of Mont Perdu. A great number of caves exist amongst the limestone formations, and in them valuable remains of prehistoric man have been found.

See works by Perret (1884), Prarond (1877), Taine (13th ed. 1893), Camena d'Almeida (1893), and Trutat (1894); guide-books by Gsell-Fels, Joanne, and Murray; and Count Henry Russell, *Pau, Biarritz, and the Pyrenees* (new ed. 1891).

Pyrénées, Basses, a department in the south-west corner of France, between the Landes and Spain, and having the Bay of Biscay on the west. Area, 2946 sq. m.; pop. (1891) 425,027. It is divided into the arrondissements of Pau, Oloron, Orthez, Bayonne, and Mauléon. Chief town, Pau. The department occupies the northern slopes of the Western Pyrenees (3000–9800 feet), offshoots from which divide the department into a number of valleys, traversed by mountain-streams (*gaves*). The chief are the Gave d'Oloron, and Gave de Pau, and other tributaries of the Adour. The Bidassoa, with the Isle of Pheasants, where the treaty of 1659 was signed, forms the dividing line between France and Spain for a short distance. The high valleys and slopes are generally fertile, and well adapted for the growth of the vine, chestnut, and other fruits. Agriculture is the principal industry; large herds of cattle and sheep are fed on the extensive pastures, and many swine in the wide forests. Of the numerous mineral springs the most important are those of Biarritz, Eaux-Bonnes, and Eaux-Chaudes. The western half of the department is the home of the Basques (q.v.).

Pyrénées, Hautes, a department of France, lying east of Basses-Pyrénées, is a part of the old province of Gascony. As its name implies, it contains the loftiest summits of the Pyrenees (q.v.), and is divided into the three arrondissements of Tarbes, Argelès, and Bagnères de Bigorre; chief town, Tarbes. The principal rivers are the Adour and the Gave de Pau. The climate is generally mild in the plains and sheltered valleys. The well-cultivated and artificially watered lowlands yield good crops of cereals, leguminous plants, and fruits of every kind, including the grape. Cattle, sheep, and swine are reared. Marble and slate are quarried. In this department are the springs of St Sauveur, Bagnères de Bigorre, Barèges, and Cauterets. Area, 1749 sq. m.; pop. (1891) 225,861.

Pyrénées-Orientales, a southern department of France, is bounded on the E. by the Mediterranean and on the S. by the Pyrenees. Area, 1591 sq. m.: pop. (1891) 210,125. It is divided into the three arrondissements of Perpignan, Prades, and Céret. The chief town is Perpignan. Like the other Pyrenean departments, this one embraces a series of parallel valleys formed by spurs from the Pyrenees. A plain occupies all the north and east of the department. Agriculture is extensively prosecuted, but wines constitute the wealth of the district, and include the red wines of Roussillon, the white muscatel of Rivesaltes, and others. This department takes the front rank as a producer of iron ore; granite, slate, and limestone are quarried. There are mineral springs at Amélie-des-Bains, and elsewhere.

Pyrethrum, a genus of plants belonging to the natural order Compositæ. The species are by some botanists included in the genus Chrysanthemum. Feverfew (q.v.), a native of Britain, is a notable species. A handsome double-flowered variety is cultivated in gardens for ornament; and Golden Feather, so much employed in bordering, &c. in the bedding-out system of flower-gardening, is a yellow-leaved variety. Several other species are to be met with in flower-gardens; but the most ornamental of all is *P. roseum*, from which has sprung many beautiful varieties with double and single flowers of brilliant colours. From the flowers of the *P. roseum* Insect-powder (q.v.) or Persian powder is prepared; and the flowers are exported in large quantities for this purpose from Dalmatia and from the Caucasus region.

Pyrheliometer, a radiative thermometer (for measuring the direct heating effect of the sun's rays), consisting of a body heated by the sun's rays and a thermometer. See Thermometer.

Pyri'tes, a name employed by mineralogists to designate a large class of minerals, which are compounds of metals with sulphur, or with arsenic, or with both. They are crystalline, hard, generally brittle, and frequently yellow. The name pyrites originally belonged to the disulphide of iron, known as iron-pyrites or simply pyrite, and was given to it in consequence of its striking fire with steel (Gr. *pyr*, 'fire'), so that it was used for kindling powder in the pans of muskets before gun-flints were introduced. Pyrite (iron-pyrites) is commonly of a bright brass-yellow colour; it is often found crystallised in cubes, in which form small crystals of it are abundantly disseminated in some roofing-slates, and very large ones occur in some of the mines of Cornwall; it is also found crystallised in dodecahedrons and other forms, more rarely in oblique four-sided prisms; and it often occurs massive, globular, stalactitic, capillary, or investing

other minerals as an incrustation. Beautiful specimens of globular pyrite are found in the chalk of England. It is a very widely diffused and plentiful mineral, occurring in many different kinds of rock. It is too abundant in many coal-seams, the action of water and air changing it into sulphate of iron (vitriol), during which change so much heat is evolved that the coal is frequently kindled by it, mines become unworkable, and the progress of the fire can only be stopped, if at all, by building up portions of them to cut off the access of air, or by the admission of a plentiful supply of water. Sandstones containing pyrite ought not to be employed for building purposes, as it is prone to oxidation. Sometimes it is changed into sulphate of iron, but when other bases are present in the rock the sulphuric acid often unites with these in preference, leaving the iron of the original sulphide free. The iron then becomes oxidised, and appears as dark brown blotches. The presence of pyrite thus leads to corrosion and unsightly staining. The colour of pyrite has often caused it to be mistaken for gold, a mistake which its hardness and comparative lightness should prevent, or its ready solubility in nitric acid, and its burning before the blowpipe on charcoal with bluish flame and smell of sulphur. But it sometimes does contain a small proportion of gold, occasionally even in visible grains. This auriferous pyrite is found in Siberia and in South America. Pyrite is never used as an ore of iron, but it is much employed in the manufacture of sulphuric acid, and sulphur is obtained from it by sublimation. It is also used for the manufacture of alum. A rather unstable variety of iron disulphide of a very pale colour is called *Marcasite;* it crystallises in orthorhombic forms. Another sulphide of iron known as *Pyrrotine* (Fe_7S_8) is magnetic.

Copper Pyrites, also called *Yellow Copper* and *Chalcopyrite*, is the most abundant of all the ores of copper, and yields a large proportion (perhaps a third) of the copper used in the world. It is brass-yellow, the colour varying with the amount of copper which it contains, a rich colour indicating much copper, and a pale colour the presence of a comparatively large amount of iron; for this ore is not a sulphide of copper alone, but of copper and iron. It occurs massive and disseminated in rocks of almost every class, and is often found crystallised in octahedrons and tetrahedrons, but generally in very small crystals. It may at once be distinguished from iron-pyrites by its comparative softness, yielding readily to the knife, and by the green colour of its solution in nitric acid. Before the blowpipe, with borax and soda, it yields a bead of copper.—*Cobaltite*, an arsenio-sulphide of copper, is a principal ore of cobalt. It is generally of a silver-white colour, and occurs massive, disseminated, or crystallised in cubes, octahedrons, dodecahedrons, and polyhedrons, in schistose rocks.—*Nickelite*, used as an ore of nickel, is a compound of nickel and arsenic. It is generally found massive, and is of a copper-red colour; hence it is called by the German miners *Kupfer-nickel*, because they mistook it for an ore of copper.

Pyritz, a manufacturing town of Pomerania, 25 miles SE. of Stettin by rail; pop. 8062.

Pyrmont. See Waldeck-Pyrmont.

Pyrogallic Acid. See Gallic Acid, Photography.

Pyroligneous Acid, or Wood Vinegar, a crude commercial form of Acetic Acid (q.v.). It is made by the destructive distillation of wood, and, besides acetic acid, contains tar, creasote, wood-naphtha, and other products, which have to be removed if it is required in a very pure state. The best woods for the distiller are 'hard' woods, although all will yield it. Oak branches stripped of their bark are cut into short billets, which are placed in cast-iron retorts, and a sufficient heat applied to drive off the volatile constituents and carbonise the wood. This acid is of great use in the arts, especially in making the acetates used by dyers and calico-printers; and it is also, when very carefully purified and properly diluted with water, used extensively as a substitute for common vinegar in pickling, and even for table use. It is also used in the preservation of fish, giving them a 'smoked' flavour.

Pyromancy. See Divination, Vol. IV. p. 21.

Pyrometry, the measurement of temperatures beyond the compass of the mercurial Thermometer (q.v.). The leading methods are ocular, calorimetric, and pyrometric. The eye alone is often sufficiently accurate, and can distinguish dull red, 525° C. (say 975° F.); cherry red, 800° C. (say 1450° F.); orange, 1100° C. (2000° F.); white, 1300° C. (2350° F.); dazzling white, 1500° C. (2700° F.). Or we may use cobalt glass as a means of more sharply discriminating the changes of visible colour. Calorimetric: a lump of heated metal is thrown into a known quantity of water; the rise of temperature is measured; the temperature of the heated metal is next calculated from its weight, its specific heat, and the rise of temperature and the quantity of the water. This method admits errors from loss of time and radiation; hence only rough results are attained, comparable with one another, but not numerically reliable. Of pyrometric methods may be named expansion of air, hydrogen or nitrogen (only suited for laboratory purposes, for glass melts, metals become permeable, and porcelain is fragile), or of mercury vapour; dilatation of solids—porcelain, platinum, or iron (Professor J. F. Daniell, 1821)—whose expansions are very small and difficult to measure, as they generally take up a new set or form when alternately heated and cooled; the shrinkage of clay (Wedgwood's pyrometer) giving variable results; the actual fusion of definite metals, alloys, or enamels whose melting-points have been previously ascertained; the temperature acquired by water made to flow uniformly through a tube partially exposed to the heat to be explored; the speeds of outflow of air through an aperture at the atmospheric and at the furnace temperature (Barns, *American Journal of Science*, 1889); Siemens' electric pyrometer, which measures the change in the resistance of platinum wire exposed to the furnace heat; Becquerel's thermo-electric pyrometer, in which a thermo-electric couple (platinum-palladium) is exposed to the heat. When Le Châtelier's thermo-electric couple, consisting of platinum and platinum-plus-ten-per-cent.-of-rhodium, is used, the readings of a thermo-electric pyrometer may be consistent with one another.

The whole subject of pyrometry was carefully discussed by M. Le Châtelier before the French Société Technique de l'Industrie du Gaz at its annual meeting in 1889; and a summary of his address will be found in the *Gas World*, March 15, 1890. See also Poggendorf's *Annalen*, vol. xxix.; and for Ericsson's Solar Pyrometer, see *Nature*, vol. xxx.

Pyrope, a gem, often called *Carbuncle* and *Hyacinth* by lapidaries, which is nearly allied to garnet. Composed of silica, alumina, magnesia, lime, and the protoxides of iron, chrome, and manganese, it is always of a deep red colour, and is transparent, or at least translucent. It generally occurs in roundish grains, but rarely in imperfectly cubical crystals. Pyropes are found chiefly in Saxony and Bohemia, also at Elie in Fife (where they are called *Elie Rubies*).

Pyrophone. also called *Flame-organ*, is a musical instrument invented about 1873 by Eugene Kastner (1852–82) of Paris, in which the musical tones are produced by flames of hydrogen gas burning in tubes of different sizes and lengths, arranged somewhat as in an ordinary organ.

Pyrophorus (from the Gr. *pyr*, 'fire,' and *pherō*, 'I bear') is a term applied to any substances which take fire from the rapidity with which they are oxidised. If iron, cobalt, or nickel be reduced by hydrogen from its oxide at a low red heat, it is obtained in a state of such extreme division as to become incandescent by the oxidising action of the atmosphere; and the tendency to rapid oxidation is much increased by the interposition of some infusible matter, as a little alumina or magnesia, between the particles of the oxide. This is probably due to the cohesion of the minute particles of the reduced metal being thus mechanically prevented, and the access of air to the surface of each particle being thus facilitated. If tartrate of lead be heated in a tube till the organic portion becomes charred, the metallic lead is reduced to a state of extreme subdivision, and usually takes fire when poured into the air. If finely-powdered sulphate of potash be mixed with half its weight of lamp-black, and heated in a covered crucible, the sulphate is reduced to sulphide of potassium, which remains in a finely-divided state, mixed with the excess of carbon, and takes fire spontaneously in the air from the rapid absorption of oxygen. These are amongst the best examples of pyrophori.

Pyrosis. See INDIGESTION.

Pyrosoma. a genus of compound or colonial Tunicates, sometimes called 'fire-flames' on account of their brilliant phosphorescence. The colonies are hollow cylinders, open at one end, and the walls are formed of hundreds of individuals. These have inhalent apertures on the exterior, while their exhalent apertures open into the cavity of the cylinder, thus producing a gentle current, by means of which the colony is slowly propelled through the water with the closed end foremost. Several species occur in the warmer seas, and *P. giganteum* is from 2 to 3 feet long. See ASCIDIANS, PHOSPHORESCENCE.

Pyrotechny. the art of making fireworks, is of unknown antiquity. It was practised amongst the Chinese from very early times, and has attained with them so much perfection that the beauty and ingenuity of their devices have often been admired by Europeans. Fireworks, as the name is now understood, were hardly known in Europe until the nature of gunpowder became known, and for a long time only very simple pyrotechnic contrivances were used.

The compositions employed for most kinds of fireworks are of the nature of gunpowder. That is to say, the mixtures of which they are made contain combustible or oxidisable substances, along with bodies available for their rapid combustion, since these latter contain large quantities of oxygen. The most frequently employed combustible materials are carbon (charcoal) or some compound of carbon, such as sugar or gum, and sulphur or a compound of this element, such as sulphide of antimony. Such bodies as charcoal and sulphur burn slowly in common air, because its oxygen is largely mixed with nitrogen, which does not support combustion; but when they are compounded with nitrates and chlorates the store of oxygen in these salts being given off by heat enables the firework composition to burn at a more or less rapid rate whenever a spark is applied to it. It is not desirable, however, to have too sudden a union of combustible matter with oxygen, hence violent explosives, like nitro-glycerine, are unsuitable for showing coloured or brilliant flames. The two most important oxidising ingredients used in firework compositions are nitrate and chlorate of potash. Iron, in the form of cast-iron or steel, and in a state of fine division, is a frequent ingredient in fireworks, and to some extent the powder or filings of antimony, zinc, magnesium, and copper are also employed. When the particles of these metals are highly heated they produce sparks and scintillations of different colours. A few substances, such as sand and sulphate of potash, are used to modify the rate of combustion.

Variety of colour is much studied in the production of fireworks, as it contributes greatly to their beauty. The colours usually seen are those given by simple metals when burned. Compounds of the metals form part of the mixtures, and these are reduced to the metallic condition in a state of very fine division by contact with the carbon present in the hot mass. A yellow colour is one of the most easily managed, any of the common compounds of sodium producing it. Copper gives a green colour when burned in a hydrogen flame, which changes to blue in the presence of a little free chlorine; so that when this metal is used for green some substance containing hydrogen is added, and when employed for blue, calomel (one of the chlorides of mercury) is put into the mixture. Nitrate of barium is also employed for green. Salts of strontium give fine crimson tints, calcium compounds a red, and lithium carbonate (a costly substance) a purple red. Among the substances used to produce white colours are sulphide of antimony and sulphide of arsenic.

The cases which contain the firework compositions are carefully made of paper or pasteboard, or both, pasted in layers. They are usually cylindrical in shape, and the proportion of length to diameter, and the size of openings for the escape of the burning mixtures, are matters of importance. So also is the proper mechanical construction of the framework of rotatory fireworks. Touch-paper, prepared with a solution of nitrate of potash in alcohol, is used for capping squibs, crackers, and indeed for all kinds of fireworks; quick-match of cotton-wick, which has been saturated with gunpowder, gum, and other ingredients, connects the parts of complicated designs; and portfires, small pencil-like articles filled with saltpetre, sulphur, and gunpowder, are used to fire the touch-paper cappings.

The simpler kinds of fireworks include squibs, crackers, gerbs, Roman candles, stars, sparks, maroons, theatre-fires, Bengal lights, &c. *Squibs* are small stout paper tubes filled with grained powder, to which a little charcoal, sulphur, and steel filings are sometimes added, a sufficient quantity of bursting powder being put in to cause a slight explosion at the end when fired. *Crackers* consist of a tube bent into folds, and containing meal-powder, charcoal, sulphur, saltpetre, and sometimes iron filings in varying proportions. The folds are tied by a cord; and on a cracker being fired a report is given at every turn of the tube. Serpents are tubes, some of which have a choke in the middle. When fired they take a zigzag direction, and give out a hissing noise. *Gerbs* consist of a straight cylindrical case filled with a composition which produces a bright sparkling jet of fire somewhat in the form of a waterspout. They sometimes contain coloured stars. *Roman candles* have a resemblance to gerbs. In filling them stars are placed at intervals along the tube between layers of the composition. *Stars* are of different kinds, such as simple stars, tailed stars, and pointed stars. Simple stars consist of saltpetre, sulphur, and fine gunpowder made into a paste ball with gum and spirits of wine, and dried.

Sometimes they contain iron filings. Many compositions are, however, used for stars, their various colours alone necessitating this. Sparks, or small stars, are also made of different colours. *Maroons* are small boxes, round or square, bound with a cord, and containing a composition which explodes with a loud report. *Bengal lights* consist of compositions varying according to colour, which are burned in small saucers: for example, a red light can be produced by a mixture of chlorate of potash, nitrate of strontia, sulphur, and lampblack; and a green by chlorate of potash, nitrate of baryta, chloride of lead, sulphur, and resin. *Theatre-fires* are produced by slow-burning compositions containing some colouring ingredient. They are burned without cases on a fireproof slab; and all substances obnoxious when burned indoors, such as sulphur, antimony, and arsenic, or their compounds, should be omitted in preparing them. Magnesium powder and the minute spores of one or more species of lycopodium are used to imitate lightning in theatres.

The most complicated kind of fireworks are some of the rotating wheels. These are called wheels because they have a framework of nave and spokes, round the rim of which cases of the nature of rockets are arranged. They revolve on a pin or metal spindle, and the motion is produced, as will be presently explained, by the recoil as the fire escapes from the cases, which are connected with each other by leaders. There are a number of different forms, but they may be classed under three kinds—vertical, horizontal, and spiral wheels. In the case of the last, a rod (nave) rises vertically from the centre of the horizontal wheel, forming the base, and upon this rod cases are arranged so as to form a spiral. *Pin* or *Catherine wheels* and *pastilles* consist each of a long paper case coiled round a rod in the form of a flat spiral, the case being, of course, filled with a burning composition. *Suns* are either fixed or revolving. Fixed suns are of various designs, but a common kind has a number of cases radiating from a centre, from which jets of fire proceed outwards. By a suitable arrangement the fire is communicated at the same time to the mouths of each of the cases. *Revolving suns* are somewhat similar to fire-wheels with spokes. Of ascending fireworks the *rocket* is the most familiar, and it has been known from an early period. It consists of two parts—viz. a long stick to guide it in its course, and a head. The latter, of strong paper and cylindrical in shape, has its lower portion formed into a hollow cone, base downwards, and round this cone is the burning composition. The object of the cavity is to effect a rapid combustion, which fills it with heated gases, and these, issuing downwards through a small hole in the base, force the rocket up through the air. The upper portion of the head is separated from the lower by a perforated plug of plaster of Paris, through which a fuse passes, so that when the lower portion is burned, the upper, which has a conical head, takes fire and sets off its garniture of stars, snakes, and other ornaments. When fire-arms are discharged there is a recoil, in the case of a heavy gun, of a short distance; in the case of a light cannon, with a larger charge in proportion to its weight, of a much greater distance; and in the case of a rocket which has a bulky charge in a very light barrel the recoil is great enough to send it high in the air. The motion of a fire-wheel is explained in the same way, there being a recoil caused by the backward pressure of the heated gases on the atmosphere as each case on the ring of the wheel takes fire. The *tourbillion* ascends and rotates at the same time. Upward motion is given by the fire escaping from holes on the under side of the cylinder, and rotatory motion by its finding vent from holes at the ends, but on opposite sides.

Aquatic fireworks, in which the devices which come in contact with the water require to be protected with grease or oil, consist of skimmers or water-devils, floating Chinese trees, gerbs, and Roman candles, water-mines, water fire-fountains, &c. Among recent novelties in pyrotechny are firework-pictures of battles, reviews, and other scenes. Of these perhaps the most popular is the enlargement, in lines of fire, of the portrait of an eminent person in whose honour some public gathering has taken place. The displays of fireworks on some occasions of national rejoicings in Great Britain have cost sums approaching or exceeding £30,000. The greatest displays of comparatively recent date have taken place during the visits of foreign sovereigns to the country. See also LIFE-SAVING APPARATUS, ROCKET, SIGNALS; and T. Kentish, *The Pyrotechnist's Treasury: Art of making Fireworks* (2d ed. 1887).

Pyroxenes, a group of minerals, comprising both monoclinic and rhombic forms. The monoclinic pyroxenes are silicates of lime, magnesia, and iron—alumina being absent or sparingly present in some, while others contain a larger percentage. The more important monoclinic forms are Augite (q.v.) and Diallage (q.v.), both being constituents of igneous rocks. The rhombic pyroxenes are silicates of iron and magnesia. There are three: Enstatite (q.v.), which contains less than 5 per cent. of ferrous oxide; Bronzite (q.v.), in which the percentage is from 5 to 15; and Hypersthene (q.v.), containing 15 per cent. and upwards. All these are important constituents of igneous rocks.

Pyroxylic Spirit, also called WOOD-SPIRIT and WOOD-NAPHTHA, is a mixture of acetone, methyl-alcohol, acetate of methyl, &c., obtained by the destructive distillation of wood in the manufacture of Pyroligneous Acid (q.v.). Many of its properties are the same as those of common alcohol; and now, notwithstanding a long opposition from the Revenue Board, its manufacture and importation are regularly allowed. It is of nearly equal value to alcohol in making varnishes, as it dissolves the resins, oils, and other similar substances. It has a peculiar naphtha-like odour, which is inseparable from it, and prevents its use as a potable spirit at present; but it is asserted that some makers produce it almost odourless, and that it sometimes takes the place of common alcohol in the manufacture of cheap perfumes. It is used in making Methylated Spirit (q.v.).

Pyroxylin, a name for Gun-cotton (q.v.).

Pyrrhic Dance, the most famous war-dance of the ancient Greeks, especially the Spartans. The name was said to be derived from Pyrrichos, the inventor of the dance. The *Pyrrhic measure* in prosody consisted of two short syllables. See DANCING.

Pyrrho (Gr. *Pyrrhōn*), the founder of a school of Greek scepticism, named after him, was a native of Elis, born in the third quarter of the 4th century B.C. A pupil of Anaxarchus, he followed him when he went in the train of Alexander to Asia and India. He lived to be ninety years old. Our knowledge of his teaching is derived principally from his pupil, Timon 'the Sillograph' (i.e. writer of *silloi*, 'satiric poems'); he himself left no writings. Pyrrho taught that we can know nothing of the nature of things, but that the best mental attitude is suspense of judgment, which brings with it calmness of mind. Pyrrhonism is often regarded as the *ne plus ultra* of (philosophical) scepticism: consistent Pyrrhonists were said even to doubt that they doubted.

Pyrrhus, king of Epirus, born about 318 B.C., a Greek warrior, was the son of Æacides and a distant kinsman of Alexander the Great. After experiencing many vicissitudes of fortune in his youth, he became sole king of Epirus in 295 B.C., and in the following year increased his territories by the addition of the western parts of Macedonia. In 281 B.C. a glorious prospect opened up before the eyes of the restless warrior—the conquest of Rome and the western world, which would confer on him a renown equal to that of his Macedonian kinsman. The Tarentines, a Greek colony in Lower Italy, then at war with the Romans, sent an embassy to Pyrrhus, in the name of all the Greek colonies in Italy, offering him the command of all their troops against their enemies. The king was overjoyed at the proposal, instantly accepted it, and in the beginning of 280 B.C. sailed for Tarentum with 20,000 foot, 3000 horse, 2000 archers, 500 slingers, and a number of elephants. The pleasure-loving Tarentines were far from pleased at the strict measures taken by Pyrrhus to inure them to the hardships of war. The first battle between Pyrrhus and the Romans, who were commanded by the consul, M. Valerius Lævinus, took place at the river Siris in Lucania. The contest was long, obstinate, and bloody; and Pyrrhus only succeeded by bringing forward his elephants, whose strange appearance and gigantic size excited a sudden panic among the Romans. It was a hard-bought victory for Pyrrhus, who said, as he looked upon the field, thick-strewn with his numerous dead, 'Another such victory, and I must return to Epirus alone.' Hence the phrase 'Pyrrhic victory.' Many of the Italian nations now joined Pyrrhus, and he proceeded on his march towards Central Italy. The Roman senate would have accepted the terms proposed by Cineas, the eloquent ambassador of Pyrrhus, but for the stirring speech of old Ap. Claudius Cæcus, which made them resolve to 'fight it out' with the foreigner. Pyrrhus, after penetrating to within 20 miles of Rome, found it impossible to proceed farther with safety, as one Roman army occupied the city and another hung upon his flanks and rear. He therefore withdrew to Campania, and thence to Tarentum, where he wintered. The campaign of 279 was carried on in Apulia, and the principal engagement took place near Asculum. The Romans were again defeated; but Pyrrhus himself lost so heavily that he felt it impossible to follow up his victory, and again withdrew to Tarentum. Here a truce was entered into between the belligerents, and Pyrrhus passed over into Sicily to assist the Sicilian Greeks against the Carthaginians, 278. His first exploits in that island were both brilliant and successful; but the repulse which he sustained in his attack on Lilybæum broke the spell which invested his name. Soon afterwards he became involved in misunderstandings with the Greeks, and in 276 he quitted the island in disgust to renew his war with Rome. While crossing over to the mainland the Carthaginians attacked him and destroyed seventy of his ships. In 274 he fought a great battle with the Romans, under the consul Curius Dentatus, near Beneventum, and was utterly defeated, escaping to Tarentum with only a few personal attendants. He now saw himself forced to abandon Italy and return to Epirus, where he almost immediately engaged in war with Antigonus Gonatas, son of Demetrius, and king of Macedonia. His success was complete, for the Macedonian troops deserted to him *en masse*, and he once more obtained possession of the country; but nothing could satisfy his love of fighting, and in less than a year he was induced to enter on a war with the Spartans. He marched a large force into the Peloponnesus and tried to take their city, but was repulsed in all his attempts. He then proceeded against Argos, where he met his death by means of a tile hurled at him by a woman from the roof of a house, 272 B.C.

Pyrus, a genus of trees and shrubs of the natural order Rosaceæ, sub-order Pomeæ, having a five-celled fruit, with a cartilaginous endocarp and two seeds in each cell. It includes species differing very much in appearance, in foliage, and in almost everything except the characters of the flower and fruit, and formerly constituting the genera Sorbus, Aria, Aronia, &c., or included in Mespilus (see MEDLAR) and Cratægus. Some botanists separate the Apples (Malus) as a distinct genus. Amongst the species of Pyrus are some of the most valuable fruits of temperate climates and some highly ornamental trees and shrubs. See APPLE, PEAR, SERVICE, ROWAN, BEAM-TREE. The so-called *Pyrus japonica* is really a Cydonia; see QUINCE.

Pytchley, a village of Northamptonshire, 3 miles SW. of Kettering, whence the famous Pytchley Hunt takes name. Amongst more than twenty masters of the hunt the most noted have been Lord Althorp (afterwards Earl Spencer; master from 1808 to 1817), 'Squire' Osbaldeston (1827–34), and Mr Payne (1844–48). See FOXHUNTING; and H. O. Nethercote, *The Pytchley Hunt, Past and Present* (1888).

Pythagoras is for us at once the glorified and the actual founder of the Pythagoreans—a philosophical school or sect which exercised a profound and lasting influence on the course of ancient science, philosophy, and theology from pre-Socratic times in Lower Italy, and then, down to the days of the Roman empire, in Greece, in Alexandria, and elsewhere. It cannot be too carefully borne in mind that the earliest written information we have about Pythagoreanism is the fragments not of Pythagoras himself but only of Philolaus, a successor, that the school was at first mainly characterised by its ethico-religious and political tendencies, and that the founder became among later adherents the object of mystical reverence and contemplation; accordingly our knowledge about the doctrines of the Pythagoreans and about the personality of Pythagoras is extremely limited. Aristotle, for example, only speaks of the Pythagoreans in his *résumé* of Greek philosophy, and he with Plato probably only knew of Pythagoras through the oral utterances of Philolaus. Pythagoras was born in Samos about 582 B.C. As regards his education we know only that he was made acquainted with the teachings of the early Ionic philosophers, and, through his travels (which are said to have been not only among the Egyptians, but among the Phœnicians, the Chaldeans, the Persian Magi, the Indians, Jews, Druids, Thracians, &c.), with those of the Egyptian priests. About 530 he settled in Crotona, in Magna Græcia, where he founded the moral and religious school called by his name. Pythagoreanism was first a life and not a philosophy, a life of moral abstinence and purification, reactionary against the popular and the poetic religions, but yet sympathetic towards the old (Doric) aristocratic forms and institutions. All that can be certainly attributed to Pythagoras is the doctrine of transmigration of souls, the institution of certain religious and ethical regulations, and the beginning perhaps of those investigations into numbers and the relations of numbers which made the school famous. The Pythagoreans as an aristocratic party became unpopular after the defeat of the Sybarites by the Crotoniates in 510 (see CROTONA, SYBARIS), and at first were instrumental in putting down the democratic party in Lower Italy; but the tables were afterwards turned

upon them, and they had to flee from persecution. How Pythagoras himself died is not exactly known; his death (according to tradition, at Metapontum) may be placed about 500 B.C.

The Pythagoreans adhered at first to certain mysteries—indeed, the Orphic mysteries; an examination as to fitness qualified for admission into their number; obedience and silence, abstinence and simplicity in dress and food and 'external goods,' and the habit of frequent self-examination were prescribed. The enjoined disposal of worldly goods may have helped to foster contemplation and scientific enthusiasm. This at least developed itself in the school. Pythagoras, for example, is said to have practised investigations into harmonies and the properties of numbers. Mathematical investigations were first begun by individuals, and then carried on prominently by the school. Their attention was early turned to the odd and even, to prime numbers, square numbers, &c.; and from this arithmetical standpoint they cultivated geometrical studies, number becoming for them the chief principle in space. The elementary relations of harmonies and the regular rotations of the spheres led the Pythagoreans to think of the cosmic order as a numerical one, and, like the early Greek Realists in philosophy, they took number to have a metaphysical significance—to be, as Aristotle tells us, not only the form, but the very substance of things: 'All is Number' came to be their thesis. As numerical proportions are repeated in different things, they regarded numbers also as archetypes, of which things were in a sense the ectypes. They explained the harmonious arrangement of things as that of bodies in a single all-inclusive sphere of reality, moving according to a numerical scheme, the earth itself and the fixed stars all being in progress round the central fire. (It is interesting to notice this idea so early in science of the movement of the earth.) The scheme of revolution was given them first by the decade, each number of which had a peculiar significance, especially the unit, the dnad, the square, &c. The table of contraries they also used in explaining the cosmos; this included such contrasts as the limited and the unlimited, the even and the odd, one and many, right and left, male and female, light and darkness, and so on. In all this room was naturally given to fanciful and arbitrary speculation, developed later among the Neo-Pythagoreans in such tables as 1, the point; 2, the line; 3, the surface; 4, body; 5, quality; 6, soul, and so on. To the virtues numbers were also given, justice being the square number; the soul, too, was in general a harmony chained to the body. As the Pythagoreans thought the heavenly bodies to be separated from each other by intervals corresponding to the harmonic lengths of strings, they held that the movement of the spheres gave rise to a pleasing sound called the 'harmony of the spheres.' Of the so-called 'elements' they had also numerical theories, fire being the tetrad, earth the cube, air the octahed, water the equation.

The great mathematical discovery of Pythagoras is of course the hypothenuse theorem, where the square is equal to the sum of two squares. 'Pythagorean numbers' are such numbers as are related in the way the theorem indicates —e.g. 5, 4, and 3 ($5^2 = 25 = (4^2 + 3^2) = 16 + 9$). Various other theorems are closely connected with this cardinal one; these concern chiefly the squares of the various perpendiculars which may be let fall from the different angles of the right-angled triangle upon the hypothenuse and sides. The speculations in general of the Pythagoreans may be regarded from various sides. Their formal principle of number is often said, and with truth, to mark a transition from the crude Hylozoism of Thales and the Ionic philosophers to a formal or rational or conceptual contemplation of the world, developed, say, by the Eleatics, and culminating in Plato. Their idea of a quantitative combination of elementary units became a commonplace of Greek speculative cosmology, constituting the ground for a deductive ontology. The conception-general of a measure or proportion in things is, of course, a most pronounced trait in the Greek mind. It is easy to trace in the Pythagorean doctrine of the elements and the contraries and of combination and of spheric completeness all the essential features of Greek cosmology. The influence of Pythagoras and geometrical conceptions over the mind of Plato can hardly be exaggerated. The chief interest of the Pythagoreans doubtless lay in the domain of physics, and their astronomical theories may be said to constitute their capital achievement. If we remember, too, that Pythagoras is perhaps the first Greek thinker who conceived of philosophy as first a life, a life in common, we shall see in this the beginning of the legislative and ethical view of the philosopher's function expressed in the fullest way in Plato's *Republic*. The ascetic and mystical aspects of Pythagoreanism linked it closely with Platonism in the mind of Christian idealists in later times. See NEOPLATONISM, NEO-PYTHAGOREANISM.

BIBLIOGRAPHY.—The fragments of Philolaus were published by Böckh in 1819. The brief notices Aristotle gives of the Pythagoreans in the first book of the *Metaphysics* contain almost all that is of philosophical importance in their theory. Zeller's account is quite exhaustive, and notices most that has been written on the subject (*The Pre-Socratic Schools*, Eng. trans. 1882). See also Grote's *Greece*, iv. 525–551; Chaignet, *Pythag. et la Philos. Pythag.* (1873); James Gow, *Short History of Mathematics* (1884).

Pytheas of Massilia. See GEOGRAPHY, Vol. V. p. 145.

Pythia. See DELPHI.

Pythian Games, one of the four great national festivals of the Greeks, held in the Crissæan plain, near Delphi (anciently called *Pytho*), are said to have been instituted by Apollo after vanquishing the snaky monster, Python, and were celebrated in his honour every four years. Originally the contests were restricted to singing, with the accompaniment of cithern-playing; but flute-playing, athletic contests, horseracing, contests in poetry and art were afterwards introduced, and long continued a distinguishing feature of these games, which are believed to have lasted down to nearly the end of the 4th century A.D. The prize was a laurel-wreath and the symbolic palm-branch. Several of Pindar's extant odes relate to victors in the Pythian Games.

Pythias. See DAMON.

Python, a name applied to several large serpents, especially of the genus Python, which inhabit tropical Asia, Africa, and Australia, and closely resemble both in structure and habit the Boas of the New World. The body is rarely 20 feet in length, usually indeed nearer 10, though often estimated at 40; it is plump and very muscular; the tail is prehensile; there are beside the anus two rudimentary hind limbs or 'spurs,' which have perhaps a sexual function besides being of use in climbing. The pythons usually lurk near water, among the herbage or on an overhanging tree. They seize small mammals, strangle and crush them in their coils, and swallow them slowly. They do not cover them with saliva before beginning to swallow them, reports to this effect being inferences from the appearance of the occasionally disgorged prey. After a heavy meal the serpents

are very lethargic. 'The animals on which the pythons ordinarily feed are seldom larger than a small dog, and though they may seize and overpower animals as large as a goat, to swallow them "horns and all" is absolutely impossible.' We must allow for about fifty per cent. of exaggeration in almost all the popular stories about pythons. It is true, however, that the mother reptile coils herself around her pile of eggs and incubates them for about three months. Among the pythons are the following: the Netted Python (*P. reticulatus*) of the Malay Archipelago, Burma, and Siam; *P. molurus*, the Adjiger of the Hindus; *P. regia*, the Royal Rock-snake of West Africa; *P. natalensis*,

Python (*Python sebæ*).

the Natal Rock-snake; *P. sebæ*, the 'fetich' snake of tropical Africa; and several Australasian genera—e.g. Morelia, Aspidiotes. See ANACONDA, BOA.

Pyx (Gr. *pyxis*, 'a box,' properly of boxwood), the sacred vessel used in the Catholic Church to contain the consecrated eucharistic elements which are preserved after consecration, whether for the communion of the sick or for the adoration of the faithful in the churches. It is sometimes called ciborium—a name, however, also given to the Baldachin (q.v.). The form of the pyx has varied very much at different times. Anciently it was sometimes of the form of a dove, which was hung suspended over the altar. More commonly, however, it was, as its name implies, a simple box, generally of the precious metals, or, at least, of metal plated with gold or silver. At present the pyx is commonly cup-shaped, with a close-fitting cover of the same material. The interior is ordered to be of gold, or at least plated with gold. Like all the other sacred utensils connected with the administration of the eucharist, it must be blessed either by a bishop, or by a priest delegated by a bishop.

Pyx, TRIAL OF THE, the annual trial by weight and assay of the gold and silver coins of the United Kingdom issued from the mint during the preceding year. It is so called from the Pyx—i.e. box or chest—in which are deposited specimen coins. Before the coins are weighed into bags at the mint for issue to the public, two pieces are taken out of each 'journey-weight' (180 oz. Troy in the case of gold, and 720 oz. in that of silver coin), one for assay within the mint, the other for the pyx. The latter are sealed up and deposited in the chest or pyx. The trials were formerly held at Westminster at uncertain intervals of several years, the jury being sworn before the Lord Chancellor or an archbishop, and the president once being Prince Rupert, another time Pitt. Now the trial takes place, to use the words of the Coinage Act, 1870, 'at least once in each year in which coins have been issued from the mint,' at Goldsmiths' Hall, and is made by a jury of goldsmiths presided over by the King's or Queen's Remembrancer, who from 1874 to 1886 was Sir Frederick Pollock (cf. his *Remembrances*, vol. ii. pp. 272-4). The pyx chest, having been brought to the Hall in the custody of officers of the mint, is opened in the presence of the jury, who proceed to examine the coins in regard to their number, weight, and fineness, in accordance with the provisions of an order in council dated the 29th June 1871. The standard weights used, as well as the trial-plates, are produced by an officer of the Board of Trade. The weight of the total bulk is ascertained, as well as that of selected specimen pieces, and assays are taken from a bar formed by melting a number of coins as well as from separate coins. The verdict recording the results of these several trials releases the officers of the mint from their responsibility in regard to the coinage, and affords a public guarantee that the standard of the currency is well maintained. See ASSAYING, MINT.

Q

is the seventeenth letter of our alphabet. The symbol was derived from the hieroglyphic picture of a knee (see ALPHABET); this was taken over by the Phœnicians as the letter *qoph*, which became *koppa* among the Greeks. Among the Ionian Greeks it was disused as a letter before the middle of the 5th century B.C., keeping its place only as a numeral. It was retained for a while in the Dorian alphabet, lingering longest on the coins of Corinth. On the coins of Syracuse it was replaced by *k* about 480 B.C. In the Italian alphabet, which was obtained from Greece before the letter was disused, the symbol was appropriated for the favourite Latin sound of the velar guttural *kw*. The letter *q* is absent from the Anglo-Saxon alphabet, in which the sound was expressed by *cw*, as in *cwen* for *queen*, and *cwic* for *quick*. It makes its appearance about 1160, and at first was only used for Latin or French words, such as *quarter* or *quarrel*. Before the close of the 13th century it was adopted in genuine English words, such as *qualm*, *quell*, *quick*, and *queen*. In Scotland it replaced *hw*, as in *quhat* for *hwat* (what). In English it is always followed by *u*.

Quack Doctors. Medical quackery is a product of all countries and of all ages; it flourishes among civilised and uncivilised communities alike, and was as rampant before the Christian era as it is in our own day. At all times it has found a numerous public ready and willing to be gulled, and this not only among the illiterate and vulgar, but even specially among the higher and better educated classes. In many cases royalty itself has set the fashion by lending its patronage to notorious charlatans. An exact definition of what constitutes medical quackery is not easy to give. The term 'quacksalver,' in use in the 17th century for quack doctor, seems to be derived from the Dutch *kwakzalver* (Ger. *quacksalber*), meaning a person who praised loudly his own medicines or methods of cure. The first part of the word is derived from the well-known but unmusical note of the duck, and typifies the hoarse blatant tones in which itinerant medicine vendors are accustomed to laud their wares. The equivalent French term is *Charlatan*, derived from the Italian *ciarlare*, 'to chatter' (Lat. *circulari; circulator*, 'a pedlar or mountebank')—a name which also indicates their characteristic and persistent loquacity. In more ancient days the loquacity and persistence were verbal; now they are both verbal and literary, as is shown in the deluge of advertisements with which medical quacks flood the world.

Quackery may be taken to include all devices—whether practised by legally qualified medical practitioners or by those who have had no recognised medical training—which tend to deceive the public by disseminating false ideas of disease, or a belief in imaginary ailments, which vaunt certain medicines or methods of treatment as panaceas or cure-alls, or which attribute to an individual a supernatural or exceptional power of influencing and curing disease. The element of pecuniary gain or of personal vainglory also comes into a definition of quackery, as opposed to the singleness of purpose and devotion to the interests of the patient which are traditionally held to be the guiding principles of the orthodox practitioner of medicine. Perhaps the most amusing description of quacks and their methods has been given by Goldsmith in his *Citizen of the World*, and it is as true and as trenchant to-day as it was then. He says: 'Whatever may be the merits of the English in other sciences, they seem peculiarly excellent in the art of healing. There is scarcely a disorder incident to humanity against which they are not possessed with a most infallible antidote. The professors of other arts confess the inevitable intricacies of things, talk with doubt, and decide with hesitation. But doubting is entirely unknown in medicine: the advertising professors here delight in cases of difficulty; be the disorder ever so desperate or radical, you will find numbers in every street, who, by levelling a pill at the part affected, promise a certain cure without loss of time, knowledge of a bedfellow, or hinderance of business. When I consider the assiduity of this profession their benevolence amazes me. They not only in general give their medicines for half value, but use the most persuasive remonstrances to induce the sick to come and be cured. Sure there must be something strangely obstinate in an English patient who refuses so much health upon such easy terms.'

The Sieur de Courval, writing in 1610, gives a lamentable account of the way in which France, Germany, and Italy were overrun with medical quacks in his day. He describes them as being apostates, vagabonds, disgraced clergy, women of loose character, and rascals of all kinds, and says that they are more dangerous to mankind than vultures, for the latter devour only the dead, while the former prey upon the living. Cadet de Gassicourt, classified quack doctors in a whimsical manner in groups, families, and species, of which the following is an abridgment. *Circulatores:* Insects, very venomous, of the order of suckers; common everywhere, found in all countries and all latitudes. Their external characters are very varied. Some have brilliant elytra, velvety, and studded with gold; others have them more coarsely formed, dull, not entire, and marked with rents. Their intestines have an enormous capacity, the heart is wanting or very small; they attack man exclusively, their stings being always injurious and sometimes mortal. The sting is sometimes very evident, sometimes quite hidden or little apparent. He divides them into two great groups, the *Circulatores Phanerorhynchi*, or peripatetic quacks who practise in public, and the *Circulatores Cryptorhynchi*, or *Charlatans en Chambre*. The latter are described as 'the charlatan of the aristocracy, of the bourgeoisie, and of those who do not wish to be seen consulting him in public. This honest son of toil is imbued with a sense of his own importance, his language is sententious, he speaks with assurance, and is lodged luxuriously. He is often a specialist,' and so on. These two groups are further largely subdivided, and an amusing description given of each species.

The methods of quack doctors have been the same from all time, and consist principally in attracting and impressing public attention by extraordinary surroundings and behaviour, and in loudly and persistently asseverating the virtues of their nostrums. This is essentially advertising; and while the invention of printing has stimulated many industries, there are few which it has benefited to a greater extent than that of the quack doctor, as it at once opened the way to a much wider public. The enormous modern spread of newspaper reading has further been largely turned by the quack to his own advantage, as it opens up a still wider field for the puffing of his wares. When once public attention has been caught, the battle is more than half won; patronage, popularity, and success follow almost as a matter of course. Fortunately these are frequently of a very temporary character; but, as quack doctors are essentially a migratory tribe, this drawback troubles them comparatively little. When they return to their old haunts a new crop of dupes is certain to have come up. The success of quacks must be attributed largely to an imperfect knowledge among the general public of what constitutes disease, added to which there is often an implicit faith in the curative power of drugs. There is little popular conception of what is possible or impossible in the way of healing, and thus the most absurd and extravagant statements are received as facts. Their success, however, has a deeper origin—viz. in the most potent of all human passions—the desire to preserve life. The strong desire for life, health, and the relief of pain clouds the judgment and causes the chance of relief from any source to be eagerly grasped at. The popular love of the marvellous and mysterious has also been of great assistance in pushing the fortunes of many quacks.

Quack medicines, as a rule, form no real additions to our means of treating disease. Almost without exception they are formulæ taken from some old or modern pharmacopœia, or the prescription of some well-known physician, christened with a name calculated to strike the popular fancy, and then puffed and advertised into fame. Such remedies are to be found for every real and imaginary ailment of mankind; but the happy hunting-ground of the quack is more especially in the regions of chronic, but not fatal, disease, such as the multifarious rheumatic affections, chronic skin affections, asthma, hysteria, hypochondriasis, 'nervous disorders,' and a host of others. Persons afflicted with such ailments have naturally alternations of good, bad, and indifferent health, and are often very prone to attribute what is simply natural improvement to the action of the remedy last taken. It is such people who certify so confidently and so gratefully to the curative powers of quack medicines. Cures for cancer, sterility, and consumption, various elixirs of life and youth, and single antidotes efficacious against all poisons must alone have made the fortunes of many thousands of quack doctors. The sad part of the whole matter is that mankind never seems to learn by experience; no new methods of deception are introduced, no real originality or inventive enterprise is ever shown by quacks; they rely upon exactly the same old artifices as their predeccessors did, and generation after generation are duped by them just as surely.

Quadragesima ('fortieth') is the Latin name for the whole season of Lent, with its forty days (so also its French derivative, *carême*); but the name is commonly assigned to the first Sunday in Lent, by analogy with the three Sundays which precede Lent—Septuagesima, Sexagesima, and Quinquagesima (q.v.).

Quadrant (Lat. *quadrans*, 'a fourth part'), literally the fourth part of a circle, or 90°; but signifying, in Astronomy, an instrument used for the determination of angular measurements. The quadrant consisted of a limb or arc of a circle equal to the fourth part of the whole circumference, gradnated into degrees and parts of degrees. Picart was the first who applied telescopic sights to this instrument. Quadrants were adjusted in the same way as the mural circle. Various innate defects of the quadrant—such as the impossibility of securing exactness of the whole arc, concentricity of the centre of motion with the centre of division, and perfect stability of the centre-work—led to its being superseded by the repeating circle, otherwise called the Mural Circle (q.v.). *Hadley's Quadrant* is more properly an *octant*, as its limb is only the eighth part of a circle, though it measures an arc of 90°. Its principle is that of the Sextant (q.v.).

Quadratic Equations. See EQUATIONS.

Quadrature. The 'quadrature' of a plane curve is effected when a square is found which has the same area as the given curve. Practically it is effected when any rectilinear figure of equal area has been found, for it is easy then to obtain the equivalent square. The quadrature, regarded as an arithmetical process, consists in finding the area of the curve in terms of any square unit.

The great problem in quadrature has been the *Quadrature of the Circle*. The workers in this subject may be divided broadly into two classes: (1) trained mathematicians, who clearly understand the nature of the problem and the difficulties which surround it; (2) those who do not understand the nature of the problem or its difficulties, and who think that they may, by good fortune, succeed where others have failed. The number of the workers of the second class became greatly diminished when the search for 'perpetual motion' became general. And, at the present day, the ranks (now fortunately small) of the perpetual-motionists and the circle-squarers are almost entirely composed of unfortunate individuals whose mental capacities are small, in too many cases the impairment of their faculties having been brought about by a development of their fruitless idea into monomania. Apart from its great historical interest to the mathematician, the subject scarcely merits detailed notice, except in so far as such notice may be useful in preventing further waste of mental energy by some who, were their energies properly directed, might succeed in increasing the sum of useful knowledge.

The nature of the problem may be understood from the following brief account. Let an equiangular n-gon be inscribed in a circle, and let its corners be joined to each other and to the centre. The area of each triangle so formed is $\frac{1}{2}ar\cos\theta$, where a is the base of the triangle, r is the radius of the circle, and θ is one-half of the vertical angle. Hence the area of the polygon is $\frac{1}{2}nar\cos\theta$; and this can be made as nearly equal to the area of the circle as we please by making n sufficiently large. In the limit, when n is infinite, the two areas are equal. But, when n is infinite, θ vanishes and na becomes the circumference, c, of the circle. Hence the area of the circle is $\frac{1}{2}cr$—that is to say, it is equal to the area of a triangle erected on the radius of the circle as base and of height equal to the circumference of the circle.

The arithmetical quadrature of the circle would therefore be effected if we could find the value of the ratio of the circumference to the diameter—that is, the value of π in the equation $c = 2\pi r$. The geometrical quadrature would be effected by finding a geometrical method of drawing a straight line equal in length to the circumference.

It has long been known that the arithmetical solution of the problem is impossible, for it has been proved that the quantity π is *incommensurable*. And proofs have been advanced that the geometrical quadrature is also impossible; but these proofs are by no means simple, and do not always convince those who are able to judge of their accuracy. Still, apart from such proofs, the mere consideration of the fact that (discounting incapable workers) the question has been fruitlessly attacked by the ablest mathematicians of past centuries should be sufficient to deter any reasonable person from engaging in the quest: for it follows that the probability of a solution being possible is excessively small—too small to justify the staking of a man's sanity, or at least the usefulness of his life, upon the result. Any mathematician who now considers the question seeks not for a solution, but for a simple and convincing proof that a solution is impossible. (It must be remembered that a 'geometrical' solution means a solution which involves no more postulates than those of Euclid.)

James Gregory, in 1668, gave a proof of the impossibility of the geometrical quadrature which Huygens, although he at first objected to it, finally admitted in so far as it applied to any *sector* of a circle. Newton also gave a proof of this limited problem, but his proof is not conclusive.

Archimedes was the first to give a practical measurement of the quantity π. By a consideration of the inscribed and escribed 96-gons he proved that it lies between $3\frac{1}{7}\frac{0}{0}$ and $3\frac{1}{7}\frac{0}{1}$. This result is correct only to the second decimal figure. Two Hindu measurements are 3·1416 and 3·1623. Ptolemy gives 3·141552. A great improvement on previous results was made by Peter Metius in the 16th century. His result was correct to the sixth decimal place inclusive; but its correctness was accidental, for he gave two fractions between which the result lay and took the arithmetical means of the numerators and the denominators in order to obtain his final numerator and denominator—a totally unwarranted method. Vieta gave the result correct to the ninth decimal place inclusive; Adrianus Romanus gave it correct to the fifteenth; and Van Ceulen gave it to the thirty-sixth. Snell introduced considerable improvements in the method, and gave 55 decimal figures. Abraham Sharp gave 75, Machin 100, De Lagny 128, Vega 140. The latter result is only correct to 136 places. Montucla cites an Oxford manuscript in which the result (given to 154 places) is correct to 152 places. In 1846 Dase gave a result with 200 decimals, and, in the following year, Clausen gave 250. In 1851 Shanks gave 315, which were extended by Rutherford to 350; and, shortly afterwards, Shanks gave 527, which he extended to 607. An interesting experimental method was adopted by R. A. Smith. He tossed a thin rod upon a uniformly planked floor, the length of the rod being three-fifths of the breadth of a plank. If l be the length of the rod, while b is the breadth of a plank, the probability of the rod intersecting a seam is $2l/\pi b$. From the result of 3204 tosses, he found $\pi = 3{\cdot}1412$. The true value to 20 places is 3·14159265358979323846.

Any one who is desirous of a more detailed historical account may consult De Morgan's article on the subject in his *Budget of Paradoxes* (1872).

Quadratures, Method of. This name is applied to any arithmetical method of determining the area of a curve. When the exact area is known a square whose area is equal to it can be found—hence the term 'quadratures.'

It has been shown, under the heading Calculus, that the area of a curve whose equation is $y = f(x)$ is $\int y\,dx$, and can therefore be found when the integral can be evaluated. Hence the approximate determination of the value of a definite integral is obtainable by the method of quadratures.

Let it be required to find the area bounded by a portion of a curve, the ordinates at its extremities, and the axis. The usual method of procedure is to divide the portion of the axis which is included between the two ordinates into a number of equal parts, and to erect ordinates at the points so obtained. The area is approximately equal to the product of one of the given equal parts into half of the sum of the two extreme ordinates together with the sum of all the intermediate ordinates. To obtain a very accurate result by this process the number of equidistant ordinates must be so great that the portions of the curve which are intercepted by successive ordinates are very nearly straight.

A better method, due to Simpson, consists in drawing, through the first, second, and third points obtained as above on the curve, a parabola whose axis is parallel to the ordinates, and repeating this process with the third, fourth, and fifth points, and so on—the points being chosen so that the total number of points is even. The area of the given curve will be approximately equal to the sum of the areas of the various portions of the parabolas included between successive ordinates when these ordinates are sufficiently close together. It is therefore approximately equal to one-third of the product of one of the given equal portions of the axis into the sum of the extreme ordinates together with twice the sum of all the odd intermediate ordinates and four times the sum of all the even intermediate ordinates.

When the successive equidistant ordinates are very close together, the area is approximately equal to the product of the common intercept on the axis between successive ordinates into the sum of all the ordinates. The labour involved in the estimation of an area by this process would be fatal to its employment unless the number of ordinates was small. But, if the ordinates were few in number, considerable error would in general result unless a correction could be applied. This method is adopted in that process which is known as *the* method of quadratures par excellence, and which is as follows: Let $y_0, y_1, \ldots y_n$ be the several equidistant ordinates, and let a be the intercept on the axis between y_0 and y_n. Also let s be the sum above referred to; and let $\Delta y_0 = y_1 - y_0$, $\Delta y_1 = y_2 - y_1$, &c.; $\Delta^2 y_0 = \Delta y_1 - \Delta y_0$, $\Delta^2 y_1 = \Delta y_2 - \Delta y_1$, &c.; and so on. The value of the whole area is (not s, but)

$$s - \tfrac{1}{2}\tfrac{a}{n}(y_n + y_0) - \tfrac{1}{1}\tfrac{1}{2}\tfrac{a}{n}(\Delta y_{n-1} - \Delta y_0) - \tfrac{1}{2}\tfrac{1}{4}\tfrac{a}{n}(\Delta^2 y_{n-2} + \Delta^2 y_0) - \tfrac{1}{7}\tfrac{1}{2}\tfrac{9}{0}\tfrac{a}{n}(\Delta^3 y_{n-3} - \Delta^3 y_0) - \tfrac{1}{1}\tfrac{3}{6}\tfrac{5}{0}\tfrac{a}{n}(\Delta^4 y_{n-4} + \Delta^4 y_0) - \tfrac{8}{6}\tfrac{6}{0}\tfrac{3}{4}\tfrac{5}{8}\tfrac{a}{0}\tfrac{a}{n}(\Delta^5 y_{n-5} - \Delta^5 y_0),$$ &c.

It will not in general be necessary to proceed beyond the fifth difference. As an example we shall find the area of the curve $y = x^3$ between the limits $x = 10$ and $x = 15$. In this case all differences beyond the third vanish, and $a/n = 0{\cdot}5$ if we make eleven ordinates in all. The following table represents the results:

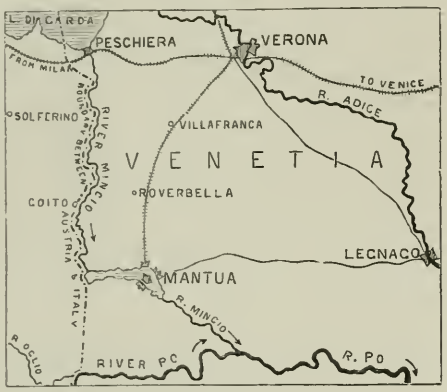
	x	y	Δy	$\Delta^2 y$	$\Delta^3 y$
0	10	1000			
			157·625		
1	10·5	1157·625		15·75	
			173·375		0·75
2	11	1331		16·5	
			189·875		0·75
3	11·5	1520·875		17·25	
			207·125		0·75
4	12	1728		18	
			225·125		0·75
5	12·5	1953·125		18·75	
			243·875		0·75
6	13	2197		19·5	
			263·375		0·75
7	13·5	2460·375		20·25	
			283·625		0·75
8	14	2744		21	
			304·625		0·75
9	14·5	3048·625		21·75	
			326·375		
10	15	3375			

Hence we have $s = 22515{\cdot}625 \times 0{\cdot}5 = 11257{\cdot}8125$; $\frac{1}{2} \times 0{\cdot}5 \times (y_{10} + y_0) = 1093{\cdot}75$; $\frac{1}{12} \times 0{\cdot}5 \times (\Delta y_9 - \Delta y_0) = 6{\cdot}61458$; $\frac{1}{24} \times 0{\cdot}5 \times (\Delta^2 y_8 + \Delta^2 y_0) = 0{\cdot}78125$. We therefore get by this method, approximately, for the value of the area the quantity 10156·67. The correct value is 10156·25, and so the error is less than one in twenty thousand.

This method is of extreme utility in the evaluation of definite integrals when rigorous processes are not attainable.

Quadriga. See CHARIOT.

Quadrilateral, the name given in history to the four fortresses of North Italy—Mantua, Verona, Peschiera, and Legnago—which form a sort of outwork to the bastion of the mountains of the Tyrol, and divide the north plain of the Po into two sections by a most powerful barrier. They



The Quadrilateral.

have figured in all the later wars that have been fought in North Italy, especially in the wars between Austria and the different Italian states.—Russia has a similar combination of four fortresses in Poland, called the Polish Quadrilateral. See NOVOGEORGIEVSK.

Quadrille, a dance of French origin, introduced about 1808 into England. It consists of consecutive dance movements, generally five in number, danced by *four* or more couples, opposite to, or at right angles to, each other. See DANCING.

Quadrille, a game at cards, very fashionable about two centuries ago. It is very similar to the Spanish game of Ombre (q.v.), with the necessary alterations to fit it for a four-handed game. When whist came into fashion after 1740, quadrille began to lose favour.

Quadrivium. See EDUCATION, Vol. IV. p. 205.

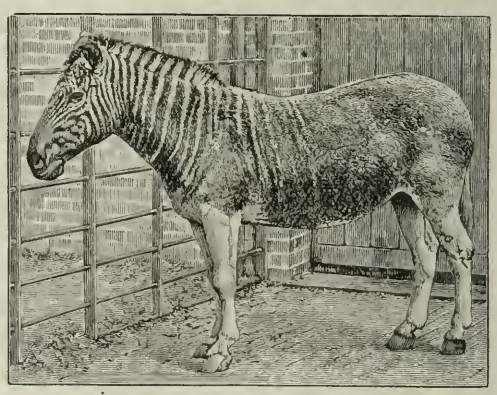
Quadroon, the offspring of a mulatto and a white person; the name indicates a man or woman who is 'quarter-blooded.'

Quadru'mana (Lat., 'four-handed'), in the zoological system of Cuvier an order of Mammalia, which he placed next Bimana, and which contained the animals most nearly resembling man in their form and anatomical character—viz. the monkey and lemur families. See ANTHROPOID APES, MAMMALS, MONKEYS.

Quadruple Alliance, a league formed August 1718 between England, France, Austria, and Holland to counteract the ambitious schemes of Alberoni. It was made upon the basis of the Triple Alliance which was formed in the January of 1717 between England, Holland, and France, and by which the clauses in the treaty of Utrecht having reference to the accession of the House of Hanover in England, the renunciation by the Spanish king of his claims on the French throne, and the accession of the House of Orleans to the French throne should the young king, Louis XV., die without issue, were guaranteed. The Spanish fleet was destroyed by Byng off Cape Passaro, while the French crossed the Pyrenees and inflicted several defeats upon the Spaniards; and at length Philip was compelled to dismiss his ambitious minister, and accept the terms of the Quadruple Alliance, January 19, 1720.

Quæstor was anciently the title of a class of Roman magistrates, reaching as far back, according to all accounts, as the period of the kings. The oldest quæstors were the *quæstores parricidii* ('investigators of murder,' ultimately public accusers), who were two in number. Their office was to conduct the prosecution of persons accused of murder, and to execute the sentence that might be pronounced. They ceased to exist as early as 366 B.C., when their functions were transferred to the *Triumviri Capitales*. But a far more important though later magistracy was the *quæstores classici*, to whom was entrusted the charge of the public treasury. They appear to have derived the epithet of *classici* from their having been originally elected by the centuries. At first they were only two in number, but in 421 B.C. two more were added. Shortly after the breaking out of the first Punic war the number was increased to eight; and as province after province was added to the Roman Republic they amounted in the time of Sulla to twenty, and in the time of Cæsar to forty. On its first institution the quæstorship (*quæstura*) was open only to patricians; but after 421 B.C. plebeians also became eligible.

Quagga (*Equus*—or *Asinus—quagga*), one of the three species of striped wild horses, or more properly wild asses, peculiar to Africa, of which the zebra is the type. Formerly found in profusion south of the Vaal River, beyond which its range seldom extended, it is believed to be now quite extinct. The illustration represents the last animal of its species owned by the Zoological Society; it

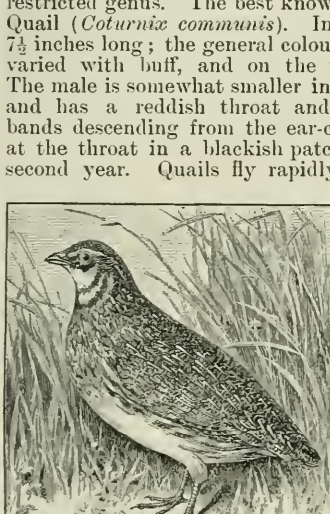


Asinus Quagga.
(From a Photograph by Messrs York & Son, London.)

was sent from the Cape by Sir George Grey in 1858. The quagga was a handsome animal, more strongly built than the mountain zebra and Burchell's zebra. The upper parts of the body were dark rufous brown, becoming gradually more fulvous, and fading to white at the rump and ventral surface, the dorsal line dark and broad, widening over the crupper. The head, neck, mane, and shoulders were striped with dark brown, gradually waxing fainter till lost behind the shoulder. It was usually

found in herds of from ten to a hundred, but often seen in troops of many hundreds on the plains of the Orange Free State and Cape Colony, and often associated with the white-tailed gnu, not seldom with ostriches. The quagga was swift and enduring, but could be run down by a first-rate horse. Its extinction was mainly wrought by the Orange Free State and Transvaal Boers, who slew thousands annually for their skins. In the old days it was tamed with success, was more tractable than the zebra, and even bred in captivity. The term Quagga is a corruption of the old Hottentot name *Quacha*, bestowed in imitation of the peculiar barking neigh of this quadruped. The quagga is not to be confounded with Burchell's zebra, which is often erroneously called quagga by hunters of the South African interior.

Quail (*Coturnix*), an Old-World genus of the Partridge family (Perdicidæ), ranging over the temperate Palæarctic, Ethiopian, and Oriental regions, and in the Australian region to New Zealand. The quails are the smallest of the partridge family. Six species are described in this restricted genus. The best known is the Common Quail (*Coturnix communis*). In size it is about 7½ inches long; the general colour above is brown, varied with buff, and on the under parts buff. The male is somewhat smaller in size, is brighter, and has a reddish throat and two dark-brown bands descending from the ear-coverts and ending at the throat in a blackish patch acquired at the second year. Quails fly rapidly, and take long and fatiguing journeys. Immense flocks visit the countries bordering the Mediterranean, especially during the spring emigration; and they are caught for food in large numbers—17,000 have been brought to Rome in one day, and in the small island of Capri, in the Bay of Naples, over 160,000 have been netted in a single season. Many remain to breed, but the majority pass northwards. In England quails are spring visitors; they are becoming scarcer, but at times there is a great influx. Northwards the numbers are fewer, but nests have been found in the northernmost mainland of Scotland, and in the Orkneys, Shetlands, and Outer Hebrides, and in summer they reach the Faroe Islands. A few remain on the south-west coast of England and in Ireland during winter, but the majority leave in October; many pass the winter in the south of Europe and in North Africa; and the species is resident in the Canaries, Madeira, and the Azores. It is also found at the Cape, in Madagascar and Mauritius, and in Egypt, while in Palestine, as of old (Exod. xvi. 13), quails come up at night and cover the land. It ranges to India and China, and passes the cold season in those countries. Its flesh is considered a delicacy, and in the countries they commonly visit the arrival of the quails is eagerly expected. Quails feed chiefly on insects and slugs, but also on grain and seeds, and they seek their food in the evening. In habit they are unsociable, unamiable, and pugnacious with their own species. They are partly polygamous, partly monogamous. The female is, however, an excellent and careful mother. She builds her nest of bits of plants, and lays from seven to fourteen eggs, pear-shaped, light brown in colour, with dark shading. The young are full grown in six weeks, and two bevies may be reared during the season. The call-note of the male is three-syllabled, and from it the quail is known as 'wet-my-lips,' or 'wet-my-feet,' and the species has also for the same reason been named *C. dactylisonans*. The other species of this genus are *C. delegorguii* (named after the discoverer Delegorgue) and *C. coromandelica*, found in South Africa and India respectively in addition to the common quail; *C. pectoralis*, found in Australia and Tasmania; *C. cainecana*, found in China; and *C. novæzelandiæ*, formerly abundant in New Zealand, but now almost extirpated by the bush fires. The Button-quails, a different group, including twenty species or more ranged under the genus Turnix or Hemipodus, are distributed in Barbary and in the Ethiopian, Indian, and Australian regions. Australia possesses a genus, Synoicus, peculiar to itself, which includes four species. The American Quails, of which there are about fifty or sixty species, are included in the family or sub-family Odontophoridæ, and differ in habit from all the Old-World forms in perching upon trees. The Virginian Quail (*Ortyx virginianus*), known as the Partridge and the Bob-White, from its calling-note, and the Californian Quail (*Lophortyx californica*) have been introduced into England as game-birds, but they have not yet become resident there.



Common Quail (*Coturnix vulgaris*).

Quain, a family of eminent medical men. (1) Jones Quain, born in November 1796, at Mallow in Ireland, studied medicine at Dublin and Paris, and in 1829 was appointed lecturer on Anatomy and Physiology in the Aldersgate School of Medicine, London. Two years later he was made professor of Anatomy and Physiology at London University, and held that post until 1836. He died in London on 27th January 1865. That well-known students' text-book, Quain's *Elements of Anatomy*, was originally written by him; the first edition appeared in 1828, the tenth in 1890. Jones Quain published also a series of elaborate *Anatomical Plates* (1838) and a translation of Martinet's *Pathology* (1835).—(2) Richard Quain, brother of the above, was born at Fermoy, Ireland, in July 1800, studied at London, and was appointed professor of Anatomy and Clinical Surgery in University College, London, in 1837. He was likewise appointed surgeon-extraordinary to the Queen, and was elected president of the Royal College of Surgeons in 1868. He died in London on 15th September 1887. Amongst his works the principal are *Anatomy of Arteries*, with folio plates (1845), *Diseases of the Rectum* (1854), *Observations on Medical Education* (1865), *Some Defects of Medical Education* (1870), and articles on *Dislocations of the Hip* and *the Knee;* he edited along with others the fifth edition of (Jones) *Quain's Anatomy*. By his will he left nearly £75,000 to University College, London, for the 'education in modern languages (especially English) and in natural science.'—(3) Sir Richard Quain, Bart., first cousin to both the above, was born at Mallow on 30th October 1816. He was Lumleian lecturer at the Royal College of Physicians (*Diseases of the Muscular Walls of the Heart*) in 1872, and Harveian Orator (*The Healing Art in its Historic and Prophetic Aspects*) in 1885, and was made physician-extraordinary to the Queen. He edited the *Dictionary of Medicine* (1882; 2d edition, 1894), and contributed to the *Trans. of the Med. and Chirurg. Soc.*, the *Lond. Jour. of Medicine*, &c. Dr Quain was made LL.D. of Edinburgh in 1889, president of the General Medical Council in 1891,

was created a baronet in 1891, and died 13th March 1898.—(4) Sir John Richard Quain, born at Mallow in 1817, the half-brother of Jones and Richard Quain, was made a judge of the Court of Queen's Bench in 1872, and justice of the High Court of Judicature in 1875. He died 12th September 1876. Along with H. Holroyd he published *The New System of Common Law Procedure* (1852).

Quakers. See Friends.

Quantification of the Predicate, a phrase belonging to Logic, and introduced by Sir W. Hamilton. According to the Aristotelian Logic, propositions are divided, according to their *quality*, into affirmative and negative, and, according to their *Quantity*, into universal and particular ('*All* men are mortal,' '*Some* men live eighty years'). If we combine the two divisions we obtain four kinds of propositions. Sir W. Hamilton affirmed that the statement of the *Quantity* of these various propositions is left incomplete; only the *subject* of each has its quantity expressed (*all* men, *some* men, *no* men); while there is implied or understood in every case a certain quantity of the *predicate*. Thus, 'All men are mortal,' is not fully stated; the meaning is, that all men are a *part* of mortal things, there being (possibly and probably) other mortal things besides men. Let this meaning be expressed, and we have a complete proposition to this effect: '*All* men are *some* (or part of) mortals,' where quantity is assigned, not only to the subject, but also to the predicate. The first result of stating the quantity of the predicate is to give eight kinds of propositions instead of four; the next result is to modify the process called the Conversion of Propositions. *Limitation* (All A is B, *some* B is A) is resolved into simple conversion, or mere transposition of premises without further change. 'All A is *some* B;' 'Some B is all A.'

The multiplication of varieties of propositions is attended with the further consequence of greatly increasing the number of *syllogisms*, or forms of deductive reasoning (see Syllogism). In the scholastic logic, as usually expounded, there are nineteen such forms, distributed under four figures (four in the first, four in the second, six in the third, five in the fourth). By ringing the changes on eight sorts of propositions, instead of the old number, four, *thirty-six* valid syllogisms can be formed in the first figure. Whether the increase serves any practical object is another question. Sir W. Hamilton also considered that the new system led to a simplification of the fundamental laws of the syllogism.

Professor De Morgan also invented and carried out into great detail a plan of expressing the quantity of the predicate. It should be noted that in the *Contemporary Review* of 1873 Professor Jevons, following Mr Herbert Spencer, recognised the fact that the discovery of the quantification of the predicate, regarded by him as the most fruitful discovery in abstract logical science since the time of Aristotle, was fully contained in George Bentham's *Outlines of a New System of Logic*. This work was published in 1827, and reviewed by Sir W. Hamilton in the *Edinburgh Review*, long ere he himself published anything on the doctrine of quantification. Boole's system of logic was based on his doctrine of quantification of the predicate. See Jevons's *Logic;* Bowen's *Treatise on Logic* (Cambridge, U.S., 1866).

Quantocks. See Somersetshire.

Quarantine (from the Fr. *quarantaine*, 'a period of forty days') is a forced abstinence from communication with the shore which ships are compelled to undergo when they are last from some port or country where certain diseases held to be infections, as yellow fever, plague, or cholera, are or have been raging. Where a quarantine is established it is a punishable offence for any person in the suspected ship to come on shore, or for any one to disembark any merchandise or goods from her, except at lazarettos, which are establishments provided for the reception of goods or passengers or crew, and where such purifying processes as the sanitary science of the time prescribes are applied. Prolonged quarantine in bad quarters is apt to produce new diseases in typhus, &c. Until a ship is discharged from quarantine she exhibits a yellow flag at the mainmasthead if she has a clean bill of health, and a yellow flag with a black spot if not clean; at night a white light is exhibited at the same place. The permit to hold intercourse after performing quarantine is called Pratique. Quarantine is not of necessity limited to a sea-frontier; and it is enforced at the frontiers between contiguous states. History declares quarantine regulations for maritime intercourse to have been first established by the Venetians in 1127 A.D.; but the practice must have been greatly older on land-frontiers; and the precautions of the Jews against leprosy indicate that a species of quarantine was enforced by them. The law for regulating quarantine in Britain is 6 Geo. IV. chap. 78, amended by 29, 30 Vict. chap. 90; power to proclaim any place subject to quarantine and prescribe regulations being vested in the Privy-council. See Bill of Health.

Quarles, Francis, a minor religious poet, belonged to a good Essex family, and was born at the manor-house of Stewards near Romford in 1592, being baptised on 8th May. He studied at Christ's College, Cambridge, and at Lincoln's Inn, and was successively cup-bearer to the Princess Elizabeth, secretary to the famous Archbishop Ussher, and, like Middleton and Ben Jonson, Chronologer to the city of London (1639). He married in 1618 a wife who bore him eighteen children, and penned shortly after his death a touching short memoir, prefixed to *Solomon's Recantation* (1645). Quarles was a bigoted royalist and churchman, suffered losses and calumny in the cause, and died 8th September 1644. He wrote abundantly both in prose and verse, and his books were extraordinarily popular in their day. Nor are his *Divine Emblems* and *Enchiridion* entirely unworthy of their reputation. Pope's lines in the *Dunciad* are familiar to every one:

> Or where the pictures for the page atone,
> And Quarles is saved for beauties not his own.

But the clever gibe is not entirely justifiable, for the *Emblems*, in spite of verbose and dull if edifying moralising, helpless bad taste, not infrequent bathos, and ever present monotony, shows wealth of fancy, excellent good sense, felicity of expression, and occasionally a bright though intermittent flash of the true poetic fire. And the *Enchiridion*, a collection of short essays and meditations, affords many an example of compact and aphoristic prose, while its antithesis and word-play are often effective and sometimes fine.

His poetical works include *A Feast for Wormes* (1620); *Hadassa, or the History of Queene Ester* (1621); *Argalus and Parthenia*, his only long poem not directly religious (written apparently about 1622; first extant ed. 1629); *Sions Elegies wept by Jeremie the Prophet* (1624); *Iob Militant* (1624); *Sions Sonets sung by Solomon the King* (1625); *Divine Poems*, a collection containing many poems printed before (1630); *The Historie of Samson* (1631); various *Elegiacal Poems* (between 1630 and 1640); *Divine Fancies: Digested into Epigrammes, Meditations, and Observations* (1632); the famous *Emblemes* (1635), to which were added in 1638 *Hieroglyphikes of the Life of Man; Solomon's Recantation* (1645); and *The Shepheards*

Oraeles delivered in Certain Eglogues (1646). The prose includes the *Enchyridion* (1640); *Observations concerning Princes and States upon Peace and Warre* (1642); *Judgement and Mercy for Afflicted Souls* (1646); *The Profest Royalist* (1645); and *The Virgin Widow*, a worthless comedy (1649). The only complete edition is that by the Rev. A. B. Grosart in the 'Chertsey Worthies Library' (3 vols. 1880-81).

Quarry. See BUILDING STONE, BLASTING.

Quart, the fourth part of a Gallon (q.v.). The ordinary *quart-bottle* is a deception, containing only the sixth part of a gallon, and often less.

Quartan Fever. See AGUE.

Quarter, a measure of weight, equal to the fourth part of a hundredweight—i.e. to 28 lb. avoirdupois. As a measure of capacity, for measuring grain, &c., a quarter contains 8 bushels.

Quarter-day. See TERM.

Quarter-deck, that part of the upper deck which extends from the mainmast or gangway amidships to the poop, or where there is no poop, to the stern; in modern turret and barbette war-ships it generally extends from the after-turret or barbette to the stern. It is the place of honour, and is considered the 'King's or Queen's Parade;' and every officer and man stepping upon it salutes it, as a mark of respect to the majesty of the throne. 'H.M. quarter-deck' is used as a promenade by officers only, at sea the weather side, and in harbour the starboard side being reserved for senior officers. Persons of distinction and officers are received on the quarter-deck; and when the captain addresses the men, or confers rewards or honours on any individual, it is on the quarter-deck that the officers and men fall in for the purpose.

Quartering. See HERALDRY; also EXECUTION, TREASON.

Quarterly Review. John Murray, conscious of the growing power and influence of the *Edinburgh Review*, and strongly disapproving of its Whig opinions, set about the organisation of a work which should counteract what he believed to be its dangerous tendencies. Accordingly, in September 1807, he wrote to Canning with a view of securing his interest in 'a work of the greatest talent and importance.' Though Canning does not seem to have replied directly, his cousin, Mr Stratford Canning, introduced Gifford (q.v.) to Murray in January 1808, and arrangements were afterwards made whereby he became its first editor. Murray sagaciously concluded on reading a review on *Marmion* in the *Edinburgh* (1808) that Scott's feelings as a gentleman and a Tory must be wounded, and that he would break his alliance with the whole Whig clique. He judged truly, and in a conference with him at Ashiesteel, in October 1808, he secured his assistance and co-operation. Scott not only wrote to his brother Thomas, C. K. Sharpe, Morritt, and Southey, on behalf of the first number, but sent a letter of advice to Gifford, and became himself a considerable contributor. The first number, rather more literary than political in tone, appeared at the end of February 1809. An edition of 4000 was sold at once, of which 850 went to Ballantyne in Edinburgh. The publisher bravely persevered, though up to the fifth number not one had paid its expenses, and though £5000 of capital was embarked in the undertaking. By 1817 it was an assured success, 14,000 being printed, and Southey, who was its 'sheet anchor,' wrote that 'Murray is a happy fellow living in the light of his own glory.' Great drawbacks were Gifford's unpunctuality, and occasional ill-health. Only two numbers appeared in 1824—No. 60, due in January, in August; and No. 61, due in April, in December. Gifford, resigning the editorship in 1824, was succeeded by John T. Coleridge, who edited only four numbers; his successor was John Gibson Lockhart (q.v.). Murray's original offer to Gifford as editor was 160 guineas a number for contributions, and £200 a year as editor; when he invited Lockhart to London his offer was £1000 a year, which could be made £1500 by contributions, and a share for three years, the profits of which would not be worth less than £1500 per annum. Besides Scott and Southey, George Ellis, Heber, Barrow, Croker, and Captain Head were considerable contributors. Croker had 99 articles in the first 100 numbers. A frequent rate of payment to Scott and Southey was £100 per article. The fashion of the times, and the lighter monthlies, have told against the *Quarterly*, which still commands, however, the best ability and scholarship in England. See Smiles, *A Publisher and his Friends* (2 vols. 1891), and articles BOOK-TRADE, MURRAY (JOHN), and PERIODICALS.

Quartermaster. In the British army the *quartermaster-general* is a staff-officer of high rank (major-general or colonel) who deals with all questions of supply, transport, marches, quarters, fuel, clothing, &c. He ranks next after the adjutant-general or senior staff-officer to the commander-in-chief at the War Office, and has under him two assistants and three deputy-assistants. The army in India has a similar staff for these duties, and so has every division; but since 1889 the title of assistant adjutant-general (B) has been substituted for that of assistant quartermaster-general on the staff at home. In a brigade the duties fall upon the brigade-major. A *quartermaster* is an officer on the staff of a depôt, a cavalry regiment, or an infantry battalion, charged with the care of stores, issues of clothing, food, forage, and fuel, allotment of barracks, tents, &c. In the native army of India he is a combatant officer of the staff-corps, but in other cases he is commissioned from the ranks as honorary lieutenant, and promoted after ten years' service, or for distinguished conduct, to the honorary rank of captain or major. In the Royal Artillery there are 44 quartermasters, in the Army Service Corps 49, and in the Royal Engineers 120, not counting those in the militia and volunteers. Several are employed, at the War Office and elsewhere, on duties different from those mentioned above; the War Office librarian, for instance, in 1891 being a quartermaster of the Royal Engineers. The daily pay of a quartermaster is 9s. for infantry; 9s. 6d. for garrison artillery and engineers, with 2s. 6d. engineer pay in addition in the latter corps; and 10s. 6d. for mounted troops, rising every five years by increments of 1s. 6d. to 15s., 15s. 6d., and 16s. 6d. respectively. After twenty years' commissioned service, or when fifty-five years of age, a quartermaster is compulsorily retired on a pension of £200 a year, or somewhat less if his total service as a soldier does not amount to thirty years. A *quartermaster-sergeant* assists the quartermaster in a regiment or battalion.

In the navy the *quartermasters* are first-class petty officers; at sea they are stationed at the *con*, their duty being to take care that the helmsmen keep the ship on her proper course, and also to see that all orders from the officer of the watch affecting the movements of the helm are promptly and correctly carried out; they also assist in heaving the log and in taking soundings when necessary. In harbour they keep regular watch at the gangways, looking out for boats arriving and leaving, and conveying the necessary orders for the carrying out of the work of the ship. Their pay depends upon their gunnery or torpedo qualifications, number of good-conduct badges, &c., and will be found under the heading PETTY OFFICER.

Quartern is a term employed in some parts of Great Britain to designate the fourth part of a peck; in liquid measure it is the fourth part of a pint, and so synonymous with the imperial gill. A quartern loaf generally weighs 4 lb.

Quarter Sessions, a court of Justices of the Peace (q.v.) established in 1350-51, and meeting once a quarter. Most of their administrative duties were in 1888 transferred to the County Councils (see COUNTY).

Quarter-staff, once a favourite weapon with the English for hand-to-hand encounters, and still sometimes used in athletic exercises, is a stout pole of heavy wood, about 6½ feet long, often bound with iron at both ends. It is grasped in the middle by one hand, the other holding halfway between the middle and end (hence apparently the name 'quarter-staff'); and the attack is made by giving it a rapid circular motion, which brings the loaded ends on the adversary at unexpected points. See *Broadsword and Singlestick*, by Allanson-Winn and Phillipps-Wolley (1890).

Quartett, a piece of music arranged for four solo voices or instruments, in which all the parts are *obligato*—i.e. no one can be omitted without injuring the proper effect of the composition. A mere interchange of melody, by which the parts become in turn principal and subordinate, without any interweaving of them, does not constitute a quartett. Quartetts for stringed instruments are generally arranged for two violins, viola, and violoncello, and are in sonata form. They originated with Haydn, and were further developed by Mozart, and notably by Beethoven, who perfected the art of part-writing. Subsequent writers are Schubert, Spohr, Mendelssohn, Schumann, and Brahms. Vocal quartetts are a frequent feature in oratorios and operas, up to the time of Wagner.

Quartodecimans. See EASTER.

Quartz, a mineral composed of silica, SiO_2. It is met with chemically pure, but not infrequently contains variable proportions of ferric oxide, manganese oxides, alumina, magnesia, lime, organic matter, &c. Very often it shows inclusions, microscopic or macroscopic as the case may be, of various minerals and fluid cavities. It occurs both in crystals and massive, the more common crystals being hexagonal prisms terminated by hexagonal pyramids. Double hexagonal pyramids are also not uncommon. It scratches glass easily, and becomes positively electrical by friction—two pieces rubbed together giving light in the dark. Quartz when pure is colourless, but, owing to the presence of foreign substances, many coloured varieties are known. Three types of quartz are recognised: (1) *Rock-crystal*, (2) *Common Quartz*, and (3) *Compact Quartz*.

Rock-crystal.—Under this head are included the varieties which are more or less transparent and assume well-marked crystalline forms. The water-clear crystals are known as *Rock-crystal*. The crystals are sometimes slender, crossing and penetrating each other in exquisite groups. They frequently enclose other substances, which are beautifully seen through the transparent rock-crystal, as slender hair-like or needle-like crystals of hornblende, asbestos, oxide of iron, rutile or oxide of titanium, oxide of manganese, &c., and such specimens are known by various fanciful names, as *Thetis' Hair-stone, Venus' Hair-stone, Venus' Pencils, Cupid's Net, Cupid's Arrows*, &c.; and sometimes the enclosed substances are small spangles of iron-glance, or crystals of iron pyrites, or native silver in fern-like leaves, or spangles of gold. Fluid inclusions are also not uncommon, as in the quartz of Poretta. Very large crystals of perfectly pure rock-crystal are sometimes found. One from the Alps, which was among the treasures carried from Italy by the French in 1797, is 3 feet in length, about 1½ feet in diameter, and weighs 7 cwt. Similar giant crystals are obtained in Madagascar. Rock-crystal was prized by the ancients, and was used by them, as it still is, for vases, cups, seals, &c. An important modern use of it is for lenses of spectacles, &c., its hardness rendering it much less liable to be scratched than glass. Lenses of rock-crystal are often called *Pebble* lenses. Rock-crystal is best developed in the crevices and cavities of crystalline schistose and granitoid rocks, such as those of Tyrol and the Alps, where it is associated with felspar, titanite, rutile, mica, chlorite, and other crystallised minerals. *Smoky Quartz*, smoky-brown; *Cairngorm*, smoky-yellow; and *Morion*, black, are varieties the colours of which have been variously attributed to the presence of small quantities of oxide of iron or manganese, or titanic acid or organic substance. Yellow and pellucid varieties of rock-crystal are known as *False Topaz*. *Amethyst* (q.v.) or *Amethystine Quartz* is purple or violet; the darker shades are often highly prized; sometimes speckled varieties of this beautiful mineral occur. When subjected to heat amethyst loses its violet colour and becomes yellow. The *Gold Topaz* and *Citrin* of jewellers are in most cases amethysts which have been treated in this way.

Common Quartz includes non-transparent varieties, some of which, however, are more or less translucent. They are either white, colourless, or coloured, the tints being generally pale, but many show intense shades of red, green, yellow, brown, &c. Sometimes they assume crystalline forms, at other times they have a granular or massive structure. The following are varieties: *Milk-quartz*, milk-white and slightly opalescent (Greenland, &c.); *Greasy Quartz*, like milk-quartz, but with a greasy lustre; *Rose-quartz*, rose-red, sometimes crimson, the colour fading on exposure (Bodenmais); *Siderite* or *Sapphire-quartz*, indigo or blue in colour, from the presence of asbestos-like fibres of blue crocidolite (Golling in Salzburg); *Ferruginous Quartz*, coloured red with ferric oxide or brown with hydrous ferric oxide; *Prase*, leek and other shades of green, which are due to needles of actinolite (Saxony, &c.); *Star-quartz*, containing within the crystal whitish or coloured eccentric radiations (Bohemia); *Fibrous Quartz*, brown, with a silky lustre, pseudomorphous after crocidolite (Cape of Good Hope); *Quartz-pisolite* is an oolitic aggregate of quartz granules (Sicily, Egypt); *Floatstone*, porous, cavernous, which floats in water until the air in its numerous cavities becomes displaced (Cornwall, &c.); *Cat's-eye*, yellow or greenish, exhibits opalescence, but without prismatic colours, an effect due to fibres of asbestos or minute tubes arranged in parallel directions (Ceylon, Harz, Fichtelgebirge, &c.).

Compact Quartz embraces compact and also finely granular aggregates, which are only translucent on their edges. Varieties are *Hornstone*, gray, brown, yellow, or red, common in many countries; *Chrysoprase*, a hornstone coloured green with nickel (Silesia); *Aventurine* (q.v.), a somewhat granular hornstone, spangled with scales of mica or goethite (Altai Mountains); *Jasper* (q.v.), brown, yellow, red, very impure, with a considerable percentage of iron.

Another group of minerals which are included in the quartz family are the chalcedonies. These are mixtures of crystalline and amorphous silica. *Chalcedony* (q.v.) itself is colourless or pale gray, or pale bluish or yellowish, translucent to semi-opaque, and occurs either in irregular layers or in mammillary, botryoidal, or stalactitic forms. The following are coloured chalcedonies: *Carnelian*,

clear red and sometimes yellowish; *Plasma*, green; *Heliotrope* or Bloodstone (q.v.), green with red spots. *Cacholong* is a dull milk-white and sometimes porous chalcedony, but is regarded by some mineralogists as a variety of opal. *Mocha-stone* or *Moss-agate* is a colourless chalcedony, containing brown moss-like dendritic inclusions. *Agate* (q.v.) consists of alternate layers of chalcedony and other varieties of crystalline and amorphous silica. *Onyx* is composed of even layers of black or brown and white chalcedony; while in *Sardonyx*, which has a similar structure, the alternate layers are red and white. For amorphous forms of silica which contain variable quantities of water, see OPAL.

Quartz is the most abundant and widely diffused of all rock-forming minerals. It is an important and characteristic ingredient of acid igneous rocks, such as granite, quartz-porphyry, &c., and forms one of the principal constituents of gneiss. In many other igneous and schistose rocks it is met with as a more or less prominent constituent. It occurs also abundantly as a secondary mineral or alteration-product in igneous and schistose rocks generally—sometimes irregularly diffused, at other times occupying cracks, crevices, cavities, &c. Many rocks, especially Archæan and Palæozoic rocks, are traversed by veins of quartz, which vary in breadth from mere lines up to many feet. In some places such veins are more or less impregnated with gold—indeed quartz-veins may be looked upon as the chief repositories of the precious metal (see GOLD).

Quartz, in crystals, is also one of the most common minerals met with lining the walls of metalliferous lodes. Amongst derivative rocks it plays an important part—conglomerates and sandstones being composed as a rule chiefly of siliceous materials. Chalcedony as a rock-constituent is a product of alteration, and is met with commonly in the vesicles and pores of many igneous rocks, or as irregular aggregates diffused through their ground-mass. It is also a common vein-mineral—the coloured chalcedonies especially occurring in this form. Agates occur in veins, and especially in the amygdaloidal cavities of igneous rocks.

Quartz-porphyry, an igneous rock, consisting of crystals of quartz and felspar scattered porphyritically through a compact or very finely crystalline ground-mass of the same minerals. It occurs both as an intrusive rock and in the form of lavas which have flowed out at the surface. Some of the quartz-porphyries which have a very compact or microfelsitic ground-mass appear to have been originally volcanic vitreous rocks—the glass having subsequently become devitrified. The non-porphyritic varieties which have a flinty or hornstone-like aspect are called *Felsite* (q.v.). 'Quartzlers-porphyry' is a name for Orthoclase-porphyry (q.v.).

Quartz-rock, or QUARTZITE, is a commonly occurring rock, composed of an aggregate of quartz-grains welded together. It is usually white, gray, or rusty yellow or reddish in colour, and has a splintery fracture. Under the microscope the grains show a rounded and often semi-fused appearance, as if they had been mutually agglutinated while in a softened condition. The siliceous paste in which the granules are frequently set has usually a crystalline texture, and now and again crystals of quartz are developed in it. The rock not infrequently shows false-bedding, and occurs in strata of variable thickness, often forming mountain-masses. Sometimes it assumes a foliated structure (*Quartz-schist*), and contains scales of mica which occasionally form layers or laminæ. The rock is obviously of sedimentary origin, and has subsequently been subjected to metamorphic action.

Quartz-trachyte. See LIPARITE.

Quasimodo Sunday. See LOW SUNDAY.

Quassia, a genus of trees and shrubs of the natural order Simarubaceæ (q.v.); having hermaphrodite flowers, with five petals combined into a tube, and much longer than the small calyx, ten stamens, five germens, and only one style; the fruit composed of five drupes. *Quassia amara* is a native of the tropical parts of America and of some of the West India Islands. It is a shrub 10 to 15 feet high, with racemes of bright-red flowers, and large pinnate leaves, the stalks of which are remarkably winged and jointed. The wood, and particularly that of the root, has a strong, purely bitter taste, and was at one time much used in medicine under the names of *Quassia-wood*, *Bitterwood*, &c. The flowers were valued in Surinam for their stomachic properties as early as the beginning of the 18th century; the wood of the root began to be known in Europe before the middle of that century, and was more fully brought into notice about 1756, by Rolander, a Swede, who had visited Surinam, and had learned its value from a negro, called Quassi, Quasha, or Quacy. This negro had discovered it about 1730, and had employed it with great success as a remedy for fevers, so that though, as Rolander says, a very simple man, he had acquired a great reputation by his use of it. Linnæus published a dissertation on it in 1761, and it was he who gave to the genus the name Quassia, from the name of the slave by whom its medicinal qualities had been made known. The true quassia is now, however, little used; its name having been transferred to the Bitterwood (q.v.) of the West Indies, *Picræna* (or *Quassia*) *excelsa*, a lofty tree, the wood of which possesses the same properties, although in an inferior degree; but this inferiority is compensated by the greater facility with which any requisite supply is obtained. It is the wood of this tree which is now sold as *Quassia-wood*, or *Quassia-chips*, in the shops. It is used to a considerable extent instead of hops for making beer, although the use of it is illegal in Britain, and beer made with it is said to become muddy and flat, and not to keep. Quassia-wood is very feebly narcotic, and a decoction of it is used for killing flies. Cabinet-work made of it is safe from all attacks of insects. In medicine it is a valuable stomachic tonic; but in fevers it is not to be compared in efficacy with cinchona and its alkaloids. Its properties depend on a bitter principle called quassiin, $C_{10}H_{12}O_3$, which is present in minute amount in the wood.

Quassia: Bitterwood (*Picræna excelsa*), branch with bisexual flowers: *a*, fruit.
(Bentley and Trimen.)

Quaternary, or POST-TERTIARY, the fourth great division of the fossiliferous strata, which embraces the Pleistocene (q.v.) or Glacial and Post-glacial (q.v.) and Recent systems.

Quaternions (or 'sets of four'), the name of a calculus of peculiar power and generality invented by Sir William Rowan Hamilton (q.v.) of Dublin. As a geometry, it primarily concerns itself with the operations by which one directed quantity or Vector (q.v.) is changed into another. Such an operation is called a quaternion, for reasons which will appear hereafter. From this point of view alone we shall discuss it here. We assume the law of vector addition, which asserts that the vector or directed line AC (see fig. 1) is equal to the sum of the vectors AB and BC—or any other directed lines parallel and equal to them. For example, the resultant of two velocities or coterminal forces is a vector equal to the vector sum of the components (see COMPOSITION). Quantities which do not involve the idea of direction or directedness are called *Scalars*; such are the quantities used in arithmetic and ordinary algebra. Parallel vectors can all be represented as scalar multiples of one another, or (better) of the parallel vector whose length is unity. By the latter representation, the scalar multiple gives the length or *tensor* of the vector. Thus any vector α may be factorised into its tensor and directed unit part. This is symbolised by the equation $\alpha = T\alpha U\alpha$, where T and U appear as selective symbols of operation, separating out the length and direction respectively.

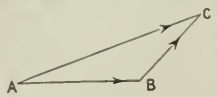


Fig. 1.

The operation which simply rotates a vector into a new direction without changing its length is a particular kind of quaternion called a *Versor*. A second application of this versor produces an extra equal rotation in the same plane—i.e. about the same axis. With every versor, therefore, are associated an axis having a definite direction and an angle through which any vector perpendicular to this axis is rotated by the versor operating on it. A very important case is the quadrantal or right versor, which turns a perpendicular vector through a right angle. Let i represent the right versor whose axis is perpendicular to the plane of the paper. Then (fig. 2) if β is any vector in the plane of the paper, the quantity $i\beta = \gamma$ gives a vector perpendicular to β and to the axis of i. A second operation gives

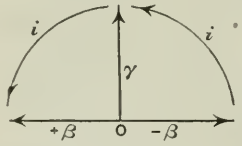

Fig. 2.

$$ii\beta = i^2\beta = i\gamma = -\beta,$$

or symbolically $i^2 = -1$. Thus the square of any right versor is negative unity. It is easy to show that ni, where n is a scalar, is an operator which still turns any appropriate vector through a right angle, but at the same time increases its tensor n times. Such an operator is a quadrantal quaternion, whose tensor is n and versor i. A quaternion can always be factorised into its tensor and versor parts.

Now let Oi, OI (fig. 3) be the axes of two right versors i and I, making angle θ with each other. Describe the sphere of unit radius with O as centre, and draw the vector OA or α perpendicular to i and in the plane O$i\mathrm{I}$. Draw OB or β perpendicular to i and α—i.e. upward from the plane of the paper; and finally draw OC or γ perpendicular to I and β. Then first $i\alpha = \beta$ and secondly $\mathrm{I}\alpha = \mathrm{I}\beta = \gamma$; so that $\mathrm{I}i\ (= \gamma/\alpha)$ is the versor which rotates α into the position γ. This versor has its axis parallel to OB, and its angle equal to the complement of θ. Thus any versor can be represented by the product of two right versors perpendicular to it and making with each other the appropriate angle. If the two right versors are themselves at right angles, their product becomes the right versor perpendicular to both. We thus arrive at what is historically the basis of quaternions—viz. Hamilton's remarkable system of mutually perpendicular right versors, ijk. As *operators* (see fig. 4) they are connected by the equations

$$ij = k = -ji$$
$$jk = i = -kj$$
$$ki = j = -ik$$
$$ijk = -1 = i^2 = j^2 = k^2.$$

The special point to notice is the non-commutative character of the process of multiplication, ij *not* being the same as ji. The discovery of the equation $ij = -ji$ on October 16, 1843, was quickly followed by the development of the whole calculus of quaternions. Now, if j and k were *vectors* instead of right versors, the equation $ij = k$ would still be true as an equation of *operations*. In fact, as is capable of easy proof, right versors obey the law of vector addition; and in the identification of unit vectors and right versors, or more generally of vectors and right quaternions, lies one of the great simplifications of the calculus. Thus the operator $(i + j)$ is a right quaternion whose axis (see fig. 4) is along the diagonal of the square of which i and j are the sides, and whose tensor is equal to the length of this diagonal.

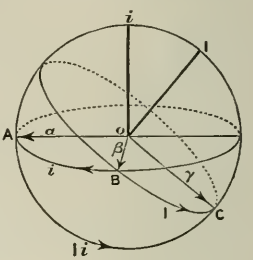

Fig. 3.

The following conclusions are readily come to. The square of every unit vector is negative unity; the product of two parallel vectors is *minus* the product of their tensors; the product of two perpendicular vectors is a third vector perpendicular to both and having its tensor equal to the product of the tensors of its factors; the product of any two unit vectors is in general a versor; the product of any two vectors is a quaternion whose tensor is the product of the tensors, and whose versor is as mentioned in the preceding sentence. The quaternion $\alpha\beta$ transforms β^{-1} into the vector α; and β^{-1}, being itself that quaternion which undoes the effect of the right quaternion β, must also be a right quaternion—i.e. a vector. In fact, β^{-1} is always equal to a scalar multiple of $-\beta$. Hence the quaternion $\alpha\beta$ is the operator which changes the vector β^{-1} into the vector α. This operation involves *four* numbers: first, the change of length; second, the angle through which the one vector must be rotated so as to bring it into parallelism with the other; and third and fourth, the two numbers necessary to fix the *aspect* of the plane in which the rotation takes place, or the direction of the axis about which rotation takes place. Thus a quaternion, in general, depends on *four* numbers, whence the name. A vector or quadrantal quaternion is a degenerate quaternion,

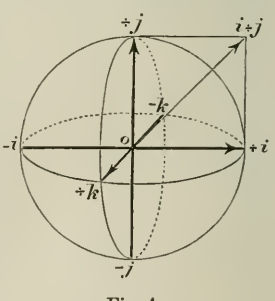

Fig. 4.

involving only *three* numbers; while a scalar, which might be defined as the quaternion which changes one vector into a parallel one, is still more degenerate, involving only *one* number—viz. itself.

There is still one very important representation of a quaternion to consider. This is done most simply as follows: Let $\alpha\beta$ be the two vectors OA, OB (fig. 5). Resolving β along and perpendicular to α we get $\beta = OM + ON$; and hence $\alpha\beta = OA.OM + OA.ON$. But OA.OM, being the product of two parallel vectors, is *minus* the product of the lengths or tensors. On the other hand, the product OA.ON, being the product of two perpendicular vectors, is a vector perpendicular to the plane of the paper with tensor equal to twice the area of the triangle OAB. Thus the quaternion $\alpha\beta$ is equal to the sum of a scalar and a vector; and generally for any quaternion (q) we have the relation

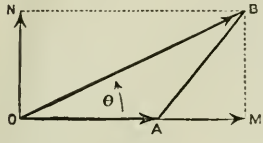

Fig 5.

$$q = S.q + V.q,$$

where S selects the scalar part and V the vector part. The geometrical meanings of S and V operating on $\alpha\beta$ are easily seen to be these—

$$S.\alpha\beta = -T\alpha T\beta \cos\theta, \qquad V.\alpha\beta = \imath T\alpha T\beta \sin\theta,$$

where $\imath$ is the unit vector perpendicular to α and β.

We end with a few illustrations. Thus, if α is a constant vector, and ρ a variable vector, the equation $S.\alpha\rho = c$, a constant, means that the resolved part of ρ along the direction of α is constant, and that therefore the extremity of ρ traces out a plane perpendicular to α. The versor that turns any line through an angle θ in a given plane has the form $\cos\theta + \imath \sin\theta$, where $\imath$ is the right versor perpendicular to that plane. Demoivre's theorem (see DEMOIVRE) at once follows if we write $\imath = \sqrt{-1}$. Finally, if β represents a force acting at the extremity of α, $V.\alpha\beta$ is the vector moment of the force about the origin; and in the almost self-evident equation

$$V.\alpha(\beta + \beta^1) = V.\alpha\beta + V.\alpha\beta^1$$

we have a completely general demonstration of Varignon's theorem of moments. See MOMENT.

Hamilton's *Lectures on Quaternions* (1853) and his *Elements of Quaternions* (1866) are still the classical works on the subject. Tait's *Elements of Quaternions* (3d ed. 1890) is probably better fitted as a text-book for the student to work through, and contains some original applications of high physical interest. Kelland and Tait's *Introduction to Quaternions* (1874) may be recommended to the beginner. Tait's treatise has been translated into French and German.

Quatre-Bras, a village of Belgium, about 10 miles SSE. of Waterloo, situated at the intersection of the great roads from Brussels to Charleroi, and from Nivelles to Namur, whence its name ('four arms'). On 16th June 1815, two days before the battle of Waterloo (q.v.), Quatre-Bras was the scene of a desperate battle between the English under Wellington and the French under Ney. The honours of the field remained with the former; but the severe defeat of Blücher the same day at Ligny compelled Wellington to retreat. The loss on the English side was 5200, on the French 4140, amongst the Allies being the Duke of Brunswick, the gallant chief of the Black Brunswickers. A monument to his memory, a bronze lion 10½ feet high, was erected in 1890.

Quatrefages, JEAN LOUIS ARMAND DE, a naturalist, was born at Berthezème (Gard) on 10th February 1810, studied medicine at Strasburg, and in 1838 was appointed professor of Zoology at Toulouse. But this post he soon resigned and went to Paris, to study further for himself. In 1850 he was elected professor of Natural History in the *Lycée Napoléon*, and in 1855 of Anatomy and Ethnology at the Natural History Museum in Paris. He devoted his attention principally to anthropology and the lower animals, especially annelids. His chief works are *L'Espèce Humaine* (1877; 8th ed. 1886; Eng. trans. 1879); *Souvenirs d'un Naturaliste* (1854; Eng. trans. 1857); *Unité de l'Espèce Humaine* (1861); *Crania Ethnica* (1875–82); *La Race Prussienne* (1879; Eng. trans. 1872); *Les Pygmées* (1887); *Histoire Naturelle des Annelés* (2 vols. 1866); *Darwin et ses Précurseurs Français* (1892); and *Théories Transformistes* (1892). He died 13th January 1892. See ANTHROPOLOGY.

Quatrefoil, an opening in tracery, a panel, &c., divided by cusps or featherings into four leaves. This form is much used as an ornament in Gothic architecture.

Quatrefoil.

Quatremère, ÉTIENNE MARC, a French orientalist, was born in Paris, 12th July 1782, and from his earliest childhood to his latest years was immersed in study; he lived more after the fashion of a mediæval recluse than a modern scholar. Employed in 1807 in the manuscript department of the Imperial Library, he was promoted in 1809 to the Greek chair in the College of Rouen, and in 1819 to the chair of Ancient Oriental Languages in the Collége de France, and in 1827 he became professor of Persian in the School for Modern Oriental Languages. He died 18th September 1857. Although a man of vast and accurate knowledge, he had little critical insight or originality. His principal works are *Recherches sur la Langue et la Littérature de l'Égypte* (1808), proving that the language of ancient Egypt is to be sought for in modern Coptic; *Mémoires Géographiques et Historiques sur l'Égypte* (1810); *Mémoire sur les Nabatéens* (1835); *Histoire des Sultans Mamelouks* (1837), from the Arabic of Makrizi; *Histoire des Mongols de la Perse* (1836), from the Persian of Rashid ed-Din; an edition of the Arabic text of the Prolegomena of Ibn-Khaldun; and a multitude of articles scattered through the pages of the *Journal Asiatique* and the *Journal des Savants*. Besides this, he gathered materials for Arabic, Coptic, Syriac, Turkish, Persian, and Armenian dictionaries.

Quattro Cento (Ital., 'four hundred,' a contraction for one thousand four hundred; cf. CINQUE CENTO), in Italian a term for the 15th century, its literature and art; the early Renaissance. Outstanding *Quattrocentisti* in art are Donatello, Della Robbia, Brunellesco, Masaccio, Ghirlandajo, Lippo Lippi, and Mantegna.

Quebec, a province of the Dominion of Canada, lies to the east of Ontario, and between that province and New Brunswick. Deducting the surface of its inland waters, including the River and Gulf of St Lawrence, the area of Quebec, including recent additions, is 347,350 sq. m. The surface of the country is varied and grand, consisting of extensive rivers and lakes, large stretches of agricultural land, and immense forests. Two ranges of mountains run through the province from south-west to north-east, that on the south side of the St Lawrence being called the Notre Dame or Green Mountains, stretching from Quebec to Gaspé, while on the north side of the river is the Laurentian Range (see CANADA). The chief river in the

province is of course the St Lawrence (q.v.), which has many tributaries of great length, the principal being the Ottawa, the St Maurice, and the Saguenay. The influence of the tide in the St Lawrence is felt as far up as the town of Three Rivers, which is nearly 900 miles from the Straits of Belle Isle. Several of the rivers are navigable for the greater part of their course, while others are used in floating timber, and besides supply manufacturing industries with almost unlimited water-power. There are numerous lakes in the province, of which the best known are Temiscamingue, Metapedia, Temiscouata, Memphremagog, and St John. The province has a coast-line of 825 miles on the Atlantic.

The climate of Quebec is very much like that of the other parts of eastern Canada, excepting perhaps that the winter is slightly colder; but, as in Ontario and in the maritime provinces, the air is generally dry and brilliant, the cold is not felt to be unpleasant, and it is no disadvantage to either the agricultural or other industries; in fact, the climate is exceedingly healthy. The soil of the province is rich and loamy, well adapted for the growth of products of all kinds. Cereals, hay, and root-crops grow everywhere in abundance. Indian corn, hemp, flax, and tobacco are also raised in many parts of the province. Fruit in considerable quantities is grown, especially apples and plums, which are exported largely. Small fruits are very abundant, and grapes ripen in the open air in many districts. Tomatoes are also a field-crop. Cattle-breeding on a large scale is carried on, and many thousands of animals are exported to Great Britain yearly. For pasturage the land of Quebec is of special excellence, particularly in the eastern townships and north of the St Lawrence.

The fisheries in the River and Gulf of St Lawrence are very prolific, and all the smaller rivers teem with fish. Along the St Lawrence especially this industry is an important one. The value of the fisheries is over $2,000,000 annually. The province is notably rich in minerals. Alluvial gold is found in various places, copper is found in the eastern townships, while iron is very generally distributed. Other minerals, such as lead, silver, platinum, and zinc, are also found, while the asbestos deposits, and those of apatite, or phosphate of lime, have achieved a reputation far beyond the limits of the province. Agriculture and dairy-farming form the chief occupations of the people at present, but manufactures, the fisheries, and commerce employ a considerable part of its inhabitants, as do also lumbering, mining, and shipbuilding. The principal articles manufactured are cloth, linen, furniture, leather, sawn timber, flax, iron and hardware, paper, chemicals, sugar, soap, india-rubber goods, boots and shoes, cotton and woollen goods, cheese (there were 672 cheese-factories and creameries in 1891), and all kinds of agricultural implements. Good wagon-roads abound, and Quebec has nearly 3000 miles of railway in operation, besides important canals, such as the Lachine, Beauharnois, and Chambly. A great portion of the total area is covered with timber, chiefly red and white pine, the produce of which forms about a third of the total exports of the province. The other principal exports are animals and their products and agricultural and dairy produce, amounting altogether to about $60,000,000 annually, the greater proportion going to Great Britain. The imports reach nearly the same value, the larger half coming from Great Britain. The revenue in 1897 amounted to $3,877,466, the expenditure to $4,892,282, and the provincial debt to $21,718,476. The revenue is derived from the subsidy from the Federal treasury, receipts from land sales, timber limits, mines, licenses, and certain other direct taxes. The affairs of the province, which is divided into 63 counties, are administered by a lieutenant-governor, who is appointed by the governor-general, an executive council consisting of 24 members appointed for life, and a legislative assembly of 73 persons elected every four years. The province is represented in the Dominion Senate by 24 members, and in the House of Commons by 65 members. The population consists largely of French-Canadians, descendants of the French settlers living in the country when it was transferred to Great Britain in 1763. The population in 1881 was 1,359,027, of whom 1,073,820, or 79 per cent. of the total, were French, 123,749 Irish, 81,515 English, and 50,923 Scotch. In 1891 the total population was 1,488,586. In 1763, at the time of the cession, the French population did not exceed 70,000, so that the progress in less than 130 years has been very remarkable, and in strange contrast to the state of things in old France. Families of twelve and fourteen are quite common amongst French-Canadians. The English population does not increase in the same way. Farms are subdivided amongst all the children as in France. In religion the Roman Catholics exceed five-sixths of the population, but the Protestant churches flourish in the cities, and the rights of the minority, in religious and educational matters, are protected by statute. Education is under the supervision of a council, which is divided into two committees for the government of Roman Catholic and Protestant schools respectively. The two Protestant universities are M'Gill at Montreal and Bishop's College at Lennoxville; Laval, the Catholic university, is at Quebec. The principal city in the province is Montreal, which now claims a population of 210,000, and is the commercial metropolis of the Dominion. The next is Quebec, the most historic city in Canada, and the seat of the provincial government.

From a historical point of view the province of Quebec is probably the most interesting part of the continent, and has already been described up to the 'Quebec Act' of 1774 in the article Canada (q.v.). The French language is still used in the province, and is sanctioned by law; the same remark applies to the French law. It is generally supposed that these privileges were conferred upon the French-Canadians by statute, but this is not the case. By the proclamation of 1763 French law was abolished in the province, and the English law substituted for it. The civil law of France was established again in 1791, and the use of the French language was officially recognised for the first time in that year; but by the Act of 1840 the French language was again set aside, and it was only legalised again in 1848. The principal historical occurrences in the 19th century have been the rebellion of 1837–38, which led to the union of Upper and Lower Canada in 1840, and the subsequent difficulties which ended in the confederation, of 1867, with the other provinces of Canada.

See *Quebec Past and Present*, by J. M. Lemoine (Montreal, 1876); *Picturesque Quebec* (1881); *Mineral Resources of Quebec* (Geol. Sur. of Canada, 1888); Sketch of the Province, by the Hon. Honoré Mercier (1890); Garneau's *History of Canada: Histoire des Canadiens Français*, by Sulte; Cassell's *Picturesque Canada;* and handbooks issued by the Canadian government.

Quebec, capital of the province of that name, is situated on a steep promontory on the north-west bank of the St Lawrence at its junction with St Charles River, 300 miles from the Gulf of St Lawrence and 180 miles below Montreal (172 by rail). The highest part of the headland is Cape Diamond, 333 feet above the level of the

river. Quebec is the most important military position in Canada. The citadel occupies an area of 40 acres, and commands a magnificent view. The harbour is spacious, and the docks and tidal basin are perfect specimens of engineering skill. On the Levis side of the river is the extensive graving-dock. The city is divided into an Upper and Lower Town. In the latter are situated the banks, warehouses, and wholesale and retail stores. In the Upper Town are the principal residences, public buildings, churches, gardens, and retail shops. Towards the west are the thriving suburbs of St John, St Louis, and St Roch's. The last named has become a place of commercial importance, with its immense warehouses and stores. To the south-west of St John are the Plains of Abraham, the historic battlefield, where a column 40 feet high has been erected to the memory of General Wolfe. Another monument, 65 feet high, dedicated to Wolfe and Montcalm, is situated in the Governor's Garden, and immediately overlooks the St Lawrence. On the Ste Foye Road is an iron pillar crowned by a bronze statue, commemorating the deeds of the British and French under Murray and Levis in 1760. There is a shaft also to the memory of Cartier and the Jesuit Brébeuf. In 1898 a statue to Champlain (q.v.), founder of the city, was unveiled by Lord Aberdeen. In the Upper Town is Dufferin Terrace, 1400 feet long, commanding a noble view. The Grand Battery is also picturesquely situated. Three handsome modern gates have replaced the old gates. The principal edifices are the parliamentary and departmental buildings, court-house, post-office, custom-house, city hall, masonic hall, basilica, the archiepiscopal palace, the Anglican Cathedral, Church Hall, and Young Men's Christian Association building. Laval University, named after the first Roman Catholic bishop of Quebec, who in 1663 founded the seminary, is an important institution, holding two charters, one from Queen Victoria (1852) and the other from Pope Pius IX. The building is spacious, well equipped, and contains a library of 90,000 volumes, a museum and art gallery, laboratory, &c. The faculties are theology, law, medicine, and arts. At the Grand Seminary theology is taught; the minor seminary is devoted to literature and philosophy. Other Roman Catholic halls of instruction are Laval Normal and Model School, the Ursuline Convent, the Convent of the Good Shepherd, and several nunneries. Morrin College, Presbyterian, is affiliated with M'Gill University. The principal benevolent institutions are the Marine Hospital, the Jeffrey Hale Hospital, the Hôtel Dieu, the Finlay Asylum, Church of England Female Orphan Asylum, Ladies' Protestant Home, St Bridget's Asylum, the Grey Nunnery, and the lunatic asylum at Beauport. Eight daily newspapers are published, five in the French language. The supply of water is continuous and good, and comes from Lake St Charles. The city is lighted with gas and electricity, the power for the latter being afforded by the Falls of Montmorency, 9 miles distant.

Quebec is connected with all the cities in America by various lines of railway, and is at the head of ocean steamship navigation to Europe. Shipbuilding has fallen off considerably of late years. The principal manufactures are worsted goods, iron-castings, machinery, cartridges, cutlery, nails, leather, musical instruments, boots and shoes, paper, tobacco, steel, &c. The chief exports are timber and lumber. The city has suffered from disastrous fires, which have led to improvement by the re-erection of finer buildings. The city elects three members to the Canadian House of Commons and three members to the Quebec House of Assembly. Quebec is the seat of the Roman Catholic cardinal-archbishop and the see of the Anglican bishop. It was originally called Stadaconé, and was visited by Cartier in 1535. In July 1608 Champlain founded the town and gave it its present name. It continued to be the centre of French trade and civilisation, as well as of the Roman Catholic missions in North America, till 1759, when it fell into the hands of the British (see WOLFE). In 1763 it was ceded to Great Britain by the treaty of Paris. Pop. (1852) 42,052; (1881) 62,446; (1891) 63,090; in 1889 to the city proper was annexed the suburb of St Sauveur, with its population of 15,000.

Quebracho is the bark of *Aspidosperma quebracho* (natural order Apocynaceæ), which grows in the Argentine Republic. It has a slightly bitter taste, and contains a number of active principles, of which the most important is aspidospermine. Both the bark and aspidospermine act like quinine in lowering the temperature in some cases of fever. They promote secretion from the kidneys, intestinal and salivary glands, and relieve dyspnœa or asthma of functional origin. The bark is taken in doses of five to eight grains, aspidospermine in doses of one grain, per day.

Quedah, or KEDAH, a state on the west side of the Malay Peninsula, with an area of 3600 sq. m. and a pop. of 30,000, nominally subject to Siam. The capital, from which the state takes its name, has about 8000 inhabitants.

Quedlinburg, a town of Prussia, at the northern base of the Harz Mountains, 56 miles by rail SE. of Brunswick. Founded by Henry the Fowler in 924, it is still in part surrounded by a wall flanked with towers. On an eminence overlooking the town stands the castle, which prior to the Reformation was the residence of the abbesses of Quedlinburg, who were independent princesses of the empire, and had a vote in the diet, and other privileges. The castle chapel contains monumental tombs of Henry I., his wife Matilda, and the Countess of Königsmark. Here Klopstock and Karl Ritter were born. The town has manufactures of sugar, wire goods, and farinaceous foods, and gardening is prosecuted on an extensive scale. Pop. (1885) 19,323.

Queen (A.S. *cwén*, 'a woman,' cognate with Dutch *kween*, Ice. *kván*, Gr. *gynē*, Sansk. *jani*), in its primary signification, the king's consort, who has in all countries been invested with privileges not belonging to other married women. The English queen, unlike other wives, can make a grant to her husband, and receive one from him. She can sue and be sued alone, and purchase land without the king's concurrence. The Statute of Treasons makes it treason to compass her death, or to violate her chastity, even with her consent, and the queen consenting is herself guilty of treason. If accused of treason, the queen is tried by the peers of the realm. The queen-consort is exempt from paying toll, and from amercements in any court. She has a Household (q.v.) of her own. It has been the usual practice to crown the queen-consort with solemnities similar to those used in the coronation of the king. In the case of Queen Caroline, consort of George IV., who was living apart from her husband, this was not done. Certain rents or revenues were anciently appropriated to the income of the queen, but no separate revenues seem ever to have been settled on any queen-consort by parliament. Her personal expenses are defrayed from the king's privy purse.

The queen-dowager is the widow of the deceased king. She retains most of the privileges which she enjoyed as queen-consort, nor does she lose her dignity by re-marriage; but it has been held that no one can marry the queen-dowager without

permission from the king, on pain of forfeiture of lands and goods. On the marriage of a king, or accession of an unmarried prince, parliament makes provision for the queen's maintenance, in case of her survivance.

The queen-regnant is a sovereign princess who has succeeded to the kingly power. In modern times, in those countries where the Salic law does not prevail, on failure of males a female succeeds to the throne. By an act of Queen Mary, the first queen-regnant in England, it was declared 'that the regall power of this realme is in the quene's majestie as fully and absolutely as ever it was in any of her most noble progenitours kinges of this realme;' and it has since been held that the powers, prerogatives, and dignities of the queen-regnant differ in no respect from those of the king. The husband of the queen-regnant is her subject; but in the matter of conjugal infidelity he is not subjected to the same penal restrictions as the queen-consort. He is not endowed by the constitution with any political rights or privileges, and his honours and precedence must be derived from the queen. The Prince Consort was naturalised by 3 and 4 Vict., words being used which enabled him to be a privy-councillor, and sit in parliament; but it was provided that His Royal Highness was not, by virtue of his marriage, to acquire any interest in the property of Her Majesty. By a decree of the Queen, Prince Albert enjoyed place, pre-eminence, and precedence next to Her Majesty.

Queen Anne Style. See RENAISSANCE.

Queen Anne's Bounty, the name given to a fund appropriated to increase the incomes of the poorer clergy of England, created out of the first-fruits and tenths, which before the Reformation formed part of the papal exactions from the clergy. The first-fruits are the first whole year's profit of all spiritual preferments, and the tenths are one-tenth of their annual profits, both chargeable according to the ancient declared value of the benefice; but the poorer livings are now exempted from the tax. Henry VIII., on abolishing the papal authority, annexed both first-fruits and tenths to the crown; and, by an act passed in 1703, these revenues were set aside, with the consent of Queen Anne, to form a perpetual fund for the augmentation of poor livings. The Archbishops, Bishops, Deans, Speaker of the House of Commons, Master of the Rolls, Privy-councillors, Lieutenants and *custodes rotulorum* of the counties, the Judges, Queen's Serjeants-at-law, Attorney- and Solicitor-general, Advocate-general, Chancellors and Vice-chancellors of the two Universities, Lord Mayor and Aldermen of London, and mayors of the several cities, and by supplemental charter the officers of the Board of Green Cloth, the Queen's Council, and the four Clerks of the Privy-council were made a corporation by the name of 'The Governors of the Bounty of Queen Anne, for the augmentation of the Maintenance of the Poor Clergy;' and to this corporation was granted the revenue of first-fruits and tenths. The governors' grants consist of capital sums of £200 to meet benefactions of money, land, tithes, rent-charges, stipends, &c., of equal value, offered on behalf of benefices not exceeding £200 in net annual income. A benefaction may be offered and a grant sought either for the augmentation of the endowment of a benefice, or towards the cost of providing or improving a parsonage-house, &c. The application of the funds at the disposal of the governors is now made subject to a long series of statutory provisions. The annual revenue in 1890 was £176,896. See Cripps, *Laws of the Church and Clergy.*

Queen Anne's Farthings. See FARTHING.

Queenborough, a village on the Isle of Sheppey, Kent, 2 miles S. of Sheerness, was founded by Edward III. (1369), and named after Queen Philippa. A line of steamers sail daily between Queenborough and Flushing in Holland. Pop. 982.

Queen Charlotte's Islands, a group to the north of Vancouver Island, off the coast of British Columbia. Area, 5100 sq. m. The two principal islands, Graham and Moresby, have a length of 160 and a greatest breadth of nearly 70 miles. The climate is healthy, but very rainy. Anthracite coal, copper and iron ore, and gold-bearing quartz have been found, and forests abound. The inhabitants are about 2000 Indians, who engage in fishing. —*Queen Charlotte's Sound* is a strait separating Vancouver Island, on the north, from the mainland.

Queen of the Meadow. See SPIRÆA.

Queen's Bench. See COMMON LAW.

Queensberry, WILLIAM DOUGLAS, DUKE OF, 'Old Q,' was born in 1724, and succeeded his father as Earl of March, his mother as Earl of Ruglen, and his cousin in 1778 as fourth Duke of Queensberry. He was famous for years as a patron of the turf, and infamous always for his shameless debaucheries. He is said to have 'displayed great taste in a song,' but to-day lives solely through Wordsworth's indignant sonnet, composed at Neidpath, whose venerable trees 'degenerate Douglas' had felled, to spite his heir or to dower one who he flattered himself was his daughter. After long fear of death he died unmarried, worth over a million sterling, on 23d December 1810, and was buried beneath the communion-table of St James's Church, Piccadilly. See Life by J. R. Robinson (1895).

Queensberry Plot. See LOVAT.

Queen's College, for women (43 to 45 Harley Street, London), was established in 1848, and incorporated by royal charter in 1853. It owed its existence partly to the Governesses' Benevolent Institution and partly to a movement originated by the Rev. C. G. Nicolay, and supported by the Rev. F. D. Maurice and other King's College professors. Its Committee of Education as at first constituted included the names of Maurice, Trench, and Kingsley; of Sterndale Bennett and Hullah; of Ansted and Edward Forbes; of Mulready and Richmond. Its aim is to provide for the higher education of women, in the first place by a liberal school training, and subsequently by a six years' course of college education. The college curriculum includes the school for pupils under fourteen years of age, the preparatory class for pupils too old to be admitted to the school but too backward for the first year's classes in college, and the college course of three years for the training for the grade of 'associate,' or six years or more for that of 'fellow.' This college is self-supporting, and is at present without any endowment. The students number about 360, and are chiefly day scholars, but boarders are received by authority of the council at two adjoining houses in Harley Street.

See WOMEN'S RIGHTS; the *Queen's College Calendar;* Maurice's *Queen's College; its Objects and Method* (1848). Mrs A. Tweedie, *The First College for Women* (1898).—For Irish Queen's Colleges, see IRELAND, Vol. VI. p. 202.

Queen's Counsel. See KING'S COUNSEL.

Queen's County, an inland county of Leinster, Ireland, is bounded N. by King's County, S. by Kilkenny, and W. by Tipperary, and measures 33 miles by 37 in its extreme dimensions. Area, 424,854 acres. Pop. (1841) 153,988; (1861) 90,650; (1881) 73,124; (1891) 64,639, of whom 56,743 were Catholics. The number of acres under crop in

1890 was 131,680, and of these 45,312 were under grain-crops (chiefly oats and barley), 36,538 were permanent grass, 30,650 under green-crops (mostly potatoes and turnips), and 19,180 were meadows. Nearly 14½ per cent. of the total area is barren. Queen's County is, for the most part, within the basin of the Barrow, and is flat and, except where bogs prevail, fertile. It is also drained by the Nore and crossed by the Grand Canal. On the north-western border lie the Slieve Bloom Mountains, reaching 1734 feet. Coal occurs in the south-east. Agriculture is the principal occupation; there is much dairy-farming, and a little woollen and cotton weaving. This district was made a shire in honour of Queen Mary, from whom also the chief town, Maryborough (pop. 2872), was called. The antiquities include a round tower and some ecclesiastical and feudal remains, the most important being a castle on the picturesque rock of Dunamase. The county embraces two parliamentary districts, each returning one member.

Queen's Evidence. See APPROVER.

Queensferry, a town of Linlithgowshire, 9 miles WNW. of Edinburgh, on the south shore of the Firth of Forth, which here is crossed by the great Forth Bridge (1882–90; see BRIDGE, Vol. II. p. 443). Named after St Margaret (q.v.), it has been a burgh of royalty since 1363, a royal burgh since about 1639, and a police-burgh since 1882; with Stirling, &c. it returns one member. Remains of a Carmelite friary were converted in 1890 into an Episcopal church; and one of its hotels is the Hawes Inn of Scott's *Antiquary*. Close by are the seats of the Earls of Rosebery and Hopetoun. Pop. (1841) 1233; (1891) 1531.

Queensland, youngest and second largest of the colonies included, after 1901, in the Australian Commonwealth (see AUSTRALIA), comprises an area of 668,497 sq. m., representing a country five and a half times the dimensions of the United Kingdom. It was little known until December 1823, when Surveyor-general Oxley, acting on information imparted by two castaway convicts, discovered the river which he named the Brisbane, in honour of the governor of the mother-colony of New South Wales. Queensland was proclaimed by imperial command a separate colony in 1859 under Sir George Ferguson Bowen as first governor. The coast-line is 2250 miles in extent. The southern boundary, beginning at Point Danger, generally follows the twenty-ninth parallel of south latitude. The northernmost point of the mainland is Cape York; but, since the annexation of the Torres Straits Islands, the limit may be reckoned from the parallel of 10°. Queensland is 1300 miles in length from north to south, and 800 miles at the greatest breadth. The width gradually lessens until, with Cape York peninsula, it assumes a pyramidal outline. Its western boundary for the most part is a straight line, marked by the 138th degree of longitude. Running more or less parallel with the eastern coast is a backbone of mountains, averaging a distance of 50 miles from the sea. Upon its intervening belt settlement has principally taken place. The Main Dividing Range is a continuation of the bolder Australian Alps of Victoria and the famous Blue Mountains of New South Wales. The highest peaks are Bellenden-Ker (5500 feet) and Mount Dalrymple (4250). The mean altitude of the range is 2000 feet. The east side is ridgy and thickly timbered with the eucalypti peculiar to the Antipodes. The country west of the mountains is to a large extent open downs and plains, often of the richest black soil, covered with the finest fattening herbage in the world.

Queensland is a fairly watered land. The largest rivers on the east coast are the Brisbane, Mary, Burnett, Fitzroy, Burdekin, and Johnston. There is also a western watershed, including the rivers Mulligan, Herbert, and Diamantina. The head-waters of the Thomson and Barcoo flow southward through the boundless prairie-country. The rivers Flinders, Leichhardt, Gilbert, Mitchell, and Gregory flow northward to the Gulf of Carpentaria. The eastern rivers, affording communication from the interior, have assisted in the creation of important industries and thriving ports along the island-studded coast. Rockhampton is on the Fitzroy, Maryborough on the Mary, and Mackay on the Pioneer. The principal harbour in Queensland is Moreton Bay, and between it and Thursday Island there are numerous ports of growing importance. The alluvial coast-lands are devoted to ordinary and semi-tropical agriculture and timber produce. The basaltic plains and tablelands beyond the Main Range, extending to what is still known as the 'Never Never country,' are occupied by pioneer pastoralists with their herds of sheep and cattle.

In such a colony, two-thirds of which lies within the tropics, there is a wide variety of climate and natural capabilities. The summer heat is undoubtedly great; but there is immunity from the hot winds which prevail in the other portions of Australia. The heat being dry, although the maximum register is 108° (the winter minimum being 34°), the exhilarating quality of the atmosphere is such that the hottest weather is not unbearable. For seven months of the year the climate is most enjoyable, and not inaptly compared with that of Madeira. At midsummer (Christmas time) the rainy season commences in the tropical portion, and extends more or less until March. The colony enjoys a high repute for health, gives a low death and a high birth rate, and is free from the scourges of pulmonary and contagious diseases. Invalids sent from the old country in what appear to be the last stages of consumption often regain health in Queensland, and live to become old inhabitants. The population at the 1891 census was 393,938, consisting of 223,781 males and 170,157 females. Free and assisted emigration is one of the features of government policy; and some idea of the rapid growth of Queensland may be formed from the fact that Brisbane, which in 1881 had a population of 30,955, ten years later numbered 75,000 within its five-mile radius. There are some 22,000 aborigines, mostly in the unsettled country. The revenue to June 1890 was £3,211,795; expenditure, £3,695,774; only in one of the preceding four years did the revenue exceed the expenditure. In 1890 the public debt amounted to £28,105,684—nearly £70 a head. A table of the population, revenue, comparative crops, exports, &c. of Queensland and the other Australian colonies will be found in the article AUSTRALIA.

Much of the marked prosperity of Queensland is due to the development of ocean and intercolonial steam communication. The British India Steam Navigation Company has a direct line between London and Brisbane, carrying monthly mails and despatching intermediate boats; and there is a regular coastal service to the other colonies. The dangerous Barrier Reef making it imperative for the government, from its earliest establishment, to construct harbours and improve the rivers, the coast of Queensland is now one of the best lighted in Australia. The navigable streams have been dredged at enormous cost, and the largest ocean steamships can now ascend the Brisbane River to discharge cargo at the city wharves. The postal system is worked by 834 post-offices, with a twopenny postage on inland letters and a penny for the towns. The railway system was rapidly extended in 1880–90; up to 1896, 2430 miles had been

opened for traffic, and other lines were projected or in course of construction. The total expenditure on railways to the middle of June 1890 was 15½ millions sterling. The government maintains a well-equipped series of workshops at Ipswich, one of the oldest towns, on the Bremer River, 25 miles from Brisbane. The railway system of Queensland is now directly connected with that of New South Wales. The telegraphic service, like the railways and the post-office, is under state control: the length of telegraph line is 9456 miles, and, since the opening of the South Australian Overland Line, Queensland is in telegraphic communication with the whole civilised world.

Queensland possesses a wealth of gold and other mineral resources; and machinery has reduced gold-mining to a settled and scientific industry. After the disastrous gold 'rushes' of the early days the miners profited by experience. But the real era of paying gold mining in Queensland did not begin until 1868. From that date to the end of 1896 its mines produced 11,198,190 ounces of gold, value £39,196,145. In 1889 the yield was 739,103 ounces; in 1890 it had decreased. In central Queensland is to be found the remarkable Mount Morgan (q.v.) mine. It is supposed that this unique formation, 1225 feet above the sea-level, was once a hot spring, the water of which held in solution gold which was precipitated and consolidated with other mineral matter into the curious ferruginous stone which, contrary to the previous theories of geologist and miner, has proved the most wonderful gold-bearing material in the world. Its fine and pure gold is worth four guineas an ounce, and the gross annual output has been estimated at 1½ million pounds sterling. The principal gold-fields in northern Queensland are Charters Towers, Ravenswood, Etheridge, Gilberton, and Palmer. A recently discovered gold-field is the Croydon, on the edge of the alluvial flat extending to the Gulf of Carpentaria. The Palmer is the most extensive alluvial field in the colony. Copper, tin, silver and lead, quicksilver, manganese, and iron are found in Queensland; and there are valuable coal-mines. Opals of great brilliancy and variety of colour have been found in a few localities, and specimens of the diamond, ruby, sapphire, and topaz near Stanthorpe. Agates exist in quantity.

The wool of Queensland, clipped from the merino and coarse-woolled sheep, still maintains its high character. The number of sheep in the colony in 1890 was 14,470,095; cattle, 4,872,416; and horses, 352,364. The annual exports of wool, hides, skins, and tallow represent a total value of 4½ millions. The manufactories of Queensland comprise metal-foundries, sugar-mills, tanneries, flour-mills, distilleries, saw-mills. Tweed-factories are worked in the neighbourhood of Ipswich. Of late years the bêche-de-mer and pearl fisheries of Torres Straits have been highly productive; and preserved meats have also become an established industry.

The seat of government is Brisbane, and the principal provincial towns are Rockhampton, Ipswich, Townsville, Cooktown, Maryborough, Gympie, Gladstone, Toowoomba (capital of the Darling Downs), Dalby, Roma, and Bowen. The government is vested in a governor appointed by the crown, an executive council, and two houses of parliament. The upper house or Legislative Council consists of thirty-nine life members, named by the governor, and sitting under a president elected by themselves; and the Legislative Assembly numbers seventy-two members, elected on a franchise that is virtually manhood suffrage. State aid to religion was abolished by one of the first acts of parliament. The educational system is free, secular, and compulsory, and the annual expenditure is—primary state schools, £208,747; grammar and university education, £1241; technical education, £3816. The defence of the colony was provided by act of parliament in 1884. A small permanent force, a defence contingent (whose members are paid for each day's drill), and volunteers make up an enrolment nearly 5000 strong; but every male between eighteen and sixty years old is liable for military service in an emergency. The entrance to the Brisbane River (twelve miles from the capital) is defended by a battery and torpedo works, and there are two gunboats, torpedo and packet boats, and a naval reserve.

About 418¼ million acres of land still belong to the crown, the greater part leased to squatters as sheep and cattle runs. The object of the recent governments of Queensland being to foster agricultural settlement and closer pastoral occupation, the tendency now is to leasing rather than selling and to prevent the aggregation of large estates.

Market-gardening in Queensland, even in the large towns, is principally done by Chinamen, who have the special gift of patience for the work. On the Darling Downs, which is the garden of Queensland, wheat may be grown; and oats, barley, and rye are cultivated for fodder. Maize and lucerne are the crops most commonly grown by farmers. European vegetables and fruits, turnips, mangolds, and potatoes are raised on the Darling Downs, but the vegetables which are the staple of the bush garden elsewhere are sweet potatoes, yams, and pumpkins. The growth and propagation of arrowroot is a most profitable industry. Tobacco thrives well. Cotton, rice, coffee, and even tea have been proved to be suitable for Queensland. Grapes, peaches, pine-apples, bananas, oranges, lemons, limes, citrons, mangoes, passion-fruit, and guavas bear profusely, and north of Capricorn all the fruit trees and spices of tropical value might be cultivated with profit but for the scarcity of labour. Ginger, pepper, and nutmeg are indigenous. The beautiful collection of timbers shown at the Colonial and Indian Exhibition in London emphasised the value of the forests of Queensland. Amongst the hardwoods are the ironbarks, stringy-barks, gums, and bloodwoods. There are several varieties of turpentines, and the easily-worked softwoods include four excellent pine-trees, while the red cedar, yellow-wood, silky oak, tulip-wood, and beech are prized for cabinet and ornamental purposes.

The wild animals of Queensland are neither numerous nor dangerous, always excepting the worst varieties of the snake. Alligators are numerous and destructive in the rivers of tropical Queensland. The fauna includes the usual Australian marsupials—the platypus, dingo, flying-fox, &c. Many of the birds are of gorgeous plumage. The emu roams the plains, and the cassowary is a rare appearance in the north. The rabbit has, so far, been fenced out from the southern borders with tolerable success; but this imported pest is an object of dread in Queensland, which suffered so severely, before the legislature assisted in their suppression, from the plague of kangaroos. The sea-fishing is unsurpassed, and the Moreton Bay oysters are exported in quantities to the sister colonies. From the Dugong (q.v.), besides the oil, is obtained a hide invaluable for thick machinery belting.

Queensland, in common with other Australian colonies, suffers occasionally from floods and droughts; but the necessity for artificial irrigation is now generally recognised as an essential protection for development in the future. The sugar industry, which had somewhat declined in value, in 1898–99 showed an increase of 50 per cent. on the previous year. Owing to the rigorous laws

passed to discourage the influx of Polynesian or Chinese labour (see COOLIES), the cost of cultivation increased. Proposals have been made for establishing separate northern and central colonies, and for dividing the colony into three provinces. The Federal Enabling Bill (for the federation of all the Australian colonies; see AUSTRALIA) passed both houses of the Legislature in 1899.

See H. S. Russell, *The Genesis of Queensland* (1888); A. C. Grant, *Bush Life in Queensland* (1881); J. Bonwick, *The Resources of Queensland* (1880); Arthur Nicholls, *Wild Life and Adventure in the Bush; Handbook for Emigrants to Queensland*, published by authority of the Agent General; *Queensland, its Institutions and Resources*, prepared for the Colonial Exhibition (1886); and for the aborigines, Lumholtz, *Among Cannibals* (1889).

Queen's Metal, a kind of Britannia Metal (q.v.).

Queen's Tobacco-pipe, the facetious designation of a peculiarly shaped kiln which used to be situated at the corner of the Tobacco Warehouses belonging to the London Docks. The kiln consisted of a circular brick stalk, bulging out at the bottom to a width of five feet inside. In the interior were piled up damaged tobacco and cigars, and contraband goods, such as tobacco, cigars, tea, silk, &c., which had been smuggled, books which were attempted evasions of the Copyright Act, &c., till a sufficient quantity had accumulated, when the whole was set fire to and consumed. The total value of the goods thus destroyed was enormous; and, though this wanton destruction was often censured, government continued till recent years periodically to fill and light the 'Queen's Pipe.' Seized goods are now distributed to inmates of public institutions or sold at 'custom sales,' though worthless stuff is still burned.

Queenstown, a seaport of Ireland, on the south side of Great Island, in the harbour of Cork, by rail 12 miles SE. of the city of Cork and 177 SW. of Dublin. Its original name was Cove of Cork; the present name commemorates the visit of Queen Victoria in 1849. The town is built in parallel streets on the slopes of a hill shaped like an amphitheatre. It enjoys a high reputation for its mild and salubrious climate. The splendid Roman Catholic cathedral for Cloyne diocese is the principal building. Queenstown is an important port of call, the mails from the United States being landed here and sent overland by rail to Dublin; while the British mails are in part taken on board here. Its climate is good, and it is a bathing resort. Pop. (1871) 10,334; (1881) 9755; (1891) 9123.

Queen's Town stands on an arm of the Klaas Smits River in the east of Cape Colony, 154 miles by rail N. by W. of East London and 205 miles NE. of Port Elizabeth. Pop. 500.

Quelpart, an island 60 miles off the south coast of Corea, about 40 miles long by 17 broad. It is rock-bound and mountainous, the volcanic Mount Auckland being 6500 feet high. It has fertile soil and good timber, and is populous.

Quercitron, the name both of a dyestuff and of the species of oak of which it is the bark. This oak (*Quercus coccinea*, var. *tinctoria*), also called Dyer's Oak and Yellow-barked Oak, is a native of North America—one of the noblest forest trees of the United States, found in New England, and as far south as Georgia, although there only at a considerable elevation. For the dyestuff, see DYEING, Vol. IV. p. 139.

Querétaro, an important town of Mexico, capital of Querétaro state (see MEXICO), is charmingly situated on a hilly plateau, 6273 feet above sea-level, 153 miles by rail NW. of Mexico city. It contains a government palace, a cathedral, an aqueduct supported in part upon arches 90 feet high, and two large cotton-spinning mills, employing 2300 hands. Here the Emperor Maximilian was shot by order of a court-martial, 19th June 1867. Pop. 36,000.

Quern, a primitive mill for grinding corn, the stone of which was turned by the hand. It is a contrivance of great antiquity, and so well adapted for the wants of a primitive people, that we find it perpetuated to the present day in remote districts of Ireland and some parts of the Hebrides and Shetlands. The remains of querns have been dug up in Britain, Ireland, and continental Europe wherever the traces of ancient population are found. They occur in the Scottish Earth-houses (q.v.), or cyclopean underground dwellings; in the lake-dwellings of Ireland, Scotland, and Switzerland; and abundantly among the remains of the Roman period in Britain and northern Europe. The most usual form of quern consists of two circular flat stones, the upper one pierced in the centre with a narrow funnel, and revolving on a wooden or metal pin inserted in the lower. The upper stone is occasionally ornamented with various devices; in the Roman period it is sometimes funnel-shaped, with grooves radiating from the centre. In using the quern, the grain was dropped with one hand into the central opening, while with the other the upper stone was revolved by means of a stick, inserted in a small opening near the edge. As early as 1284 an effort was made by the Scottish legislature to supersede the quern by the water-mill, which did not, however, prevent hand-mills from being largely used in Scotland down to the beginning of the 19th century. Probably the oldest British type of quern is that which was fashioned from a section of oak. A less simple variety of the hand-quern, known as the Pot Quern, and also of great antiquity, consists of a circular stone basin, with a hole through which the meal or flour escapes, and a smaller circular stone fitting into it, perforated with an opening through which the grain was thrown into the mill.

See Sir Daniel Wilson's *Archæology and Prehistoric Annals of Scotland* (1863), and Sir Arthur Mitchell's *The Past in the Present* (1880).

Quesnay, FRANÇOIS, a great French economist, was born at Mérey, near Montfort-l'Amaury, June 4, 1694, studied medicine and surgery at Paris, and in 1718 commenced practice at Mantes. He acquired a high reputation in his profession, and at his death on 14th December 1774 was first physician to the king. But the fame of the 'European Confucius,' as he was called by his followers, depends upon his speculations in political economy, in the pages of the famous *Encyclopédie* (articles 'Fermiers' and 'Grains') and various serials. Around him and his friend, M. de Gournay, gathered the famous group of the *Économistes*, also called the Physiocratic School (q.v.; and see POLITICAL ECONOMY, p. 288). Quesnay's views were systematically set forth in a little treatise, entitled *Tableaux Économiques*. Only a few copies of this work were printed about the end of the year 1758, and these have now all disappeared; yet the principles maintained by Quesnay are well known, both from the sources above mentioned, and from other treatises that have met with a better fate—his *Maximes Générales du Gouvernement Économique d'un Royaume Agricole*, the *notes* to which occupy more space than the text; *Le Droit Naturel*, included in the *Physiocratie* of Dupont de Nemours; *Analyse du Tableau Économique; Problèmes Économiques;* and *Dialogues sur le Commerce et sur les Travaux des Artisans*—collected in Oncken's edition of his *Œuvres Économiques et philosophiques* (Frankfort, 1888).

Quesnel, Pasquier, a French theologian, was born at Paris, July 14, 1634, and, after a distinguished course in the Sorbonne, entered the Congregation of the Oratory in 1657. So great was his reputation for learning and piety that at the age of twenty-eight he was appointed director of the Paris house of his Congregation. It was for the use of the young men under his care that he commenced the celebrated series *Réflexions Morales sur le Nouveau Testament*. In 1675 he published an edition of the works of Leo the Great, which in the notes was held to maintain Gallicanism (see Gallican Church), and was accordingly placed on the *Index*. Having refused to subscribe the formulary condemnatory of Jansenism required by a decree of 1684 from all members of the Oratory, Quesnel saw himself compelled to flee to the Low Countries, where he attached himself to Arnauld. He continued at Brussels his *Réflexions*, which were published in a complete form, with the approval of the Cardinal de Noailles, Bishop of Châlons, and ultimately Archbishop of Paris (1693-94). The Jesuits were unceasing in their malignant hostility, and Quesnel was denounced and flung into prison, but escaped to Holland. His book was finally condemned in 101 several propositions by the celebrated bull *Unigenitus* (1713). Quesnel spent his last years in Amsterdam, where he died December 2, 1719. A complete list of his many books will be found in Moréri's *Dict. Hist.* His Letters were edited by Le Courayer (1721-23). For the later history of Jansenism, see Sèché, *Les Derniers Jansénistes* (1891).

Quételet, Lambert Adolphe Jacques, a celebrated Belgian statistician and astronomer, was born at Ghent, 22d February 1796, and studied at the lyceum of his native city. Here at eighteen he began to teach mathematics, and five years later was appointed to this chair at the Brussels Athenæum. He superintended the building of the Royal Observatory, and became its director in 1828, while in 1836 he accepted the chair of Astronomy and Geodesy at the Brussels Military School. From 1834 he was perpetual secretary of the Belgian Royal Academy. He died 17th February 1874. His scientific work lay mostly in the regions of meteorology and statistics relating to anthropology. His greatest book is *Sur l'Homme et le Développement de ses Facultés* (1835), in which he sums up his researches on the physical and intellectual qualities of man. Both in this and in later work in the *Bulletin de la Commission Centrale de Statistique*, in *l'Anthropométrie, ou Mesure des différentes Facultés de l'Homme* (1871), and in other books and papers he shows the use that may be made of the theory of probabilities, as applied to the 'average man'—at times carrying out that method so as to arrive at a mechanical precision not justified by facts, and rejected by later writers on 'mind statistics.' Quételet's contributions to meteorology, astronomy, terrestrial magnetism, &c., in the *Mémoires* and *Bulletins* of the Belgian Royal Academy, were numerous and important. See Mailly's *Essai sur la Vie et les Travaux de Quételet* (1875), and Wolowski's *Éloge* (1875).

Quetta, known locally as Shalkot, a town near the north frontier of Beluchistan, strategically important as commanding the Bolan Pass and the Pishin Valley. Since 1887 it has been connected with the Indian railway system, and since 1877 Quetta and its district have been administered by British officers; it is now the headquarters of the British agent in Beluchistan, and of a considerable military force, and is strongly fortified. The valley is fertile, well watered, and populous. Coal and petroleum were discovered in 1890.

Quetzal. See Trogon.

Quetzalcoatl. See Mexico, Vol. VII. p. 169.

Quetzaltenango, the second city of Guatemala, the capital of a department of the same name, is on the Siguila, 95 miles W. by N. of Guatemala city. It contains an ornate church, the handsomest government buildings in the republic, a national college, and a conservatoire. The streets are lit with the electric light; the houses are built of a light-brown lava from the Cerro Quemado ('Burned Mountain'), which overhangs the city. Quetzaltenango is the centre of the trade in native cloths. Its port is Champerico, on the Pacific, from whence a railway extends inland to Retalhulen (27 miles). Pop. 20,000, mostly Indians.

Quevedo Villegas, Francisco Gomez de, was born at Madrid in 1580. His father was secretary to the queen and his mother one of her ladies in waiting. The Quevedos were one of the old families of the Montaña, the mountain-region between Burgos and Santander. The name was no doubt derived from a place on the Besaya River, but the punning motto of the scutcheon on their house in the adjacent Toranzo valley, 'I am he who stopped—*el que vedó*—the advance of the Moors,' expressed the family tradition, and, like Cervantes, Lope de Vega, Calderon, and others of the race, Quevedo was not a little proud of an ancestry that claimed a share in stemming the tide of Moslem conquest. Villegas was the name of his grandmother's family, another of the same mountain stock. He was left an orphan at an early age, and sent by his guardian to the university of Alcalá, from which he came away with such a name for varied scholarship that he may be said to have entered upon life with a reputation ready made. Apparently a quiet, studious, meditative life would have been his own choice, but chance ordered it otherwise for him. The fatal issue of a duel, brought about by his chivalrous championship of a woman who had been insulted in his presence, drove him in 1611 to the court of his friend the Duke of Ossuna, the new viceroy of Sicily; and he, perceiving in Quevedo, poet, scholar, and bookworm as he was, the capacities of an able administrator and diplomatist, made him his right-hand man, and kept him constantly employed in confidential missions to Rome, Milan, Genoa, and Venice, and when promoted to the vice-royalty of Naples, chose him as his minister of finance, an office in which Quevedo's success was only equalled by his integrity.

He was involved in the fall of Ossuna in 1619, and kept in prison for a time, but there was in fact nothing to tax him with except fidelity, and he was permitted to retire to La Torre de Juan Abad, a small estate of his in the Sierra Morena; he was allowed, however, to return to Madrid in 1623, and became a *persona grata* at the court of Philip IV. In 1626 he published his most important work, the *Política de Dios*, sketched probably in Italy, but put into shape during his banishment. He had been for ten years behind the scenes, and had watched the working of one-man-rule in its worst form under the autocracy of the Duke of Lerma, and in the *Política* he made an earnest and eloquent appeal to the king to be a king, not in name only, but in fact. 'The heart of the king,' he said, 'must be in no hand but God's.' Possibly it would never have seen the light had Philip IV. been true to the promise of his youth; but he soon grew weary of governing, and left it to Olivares, and so long as Olivares remained in power Quevedo's book continued to be a popular one. In 1628 he followed up his attack on government by favourites in an apologue entitled *Hell Reformed*. He remained, however, on friendly terms with Olivares; and if honours and high

place could have tempted him he might have had anything in the minister's gift. He would have been a valuable buttress to an unstable regime, and it was desirable to silence a man who had an awkward knack of telling the truth in a way that brought it home to the public. But Quevedo had no mind to be a favourite's favourite, and all that he could be got to accept was the purely honorary title of secretary to the king. In the winter of 1639 another way of effecting his purpose presented itself to Olivares. A memorial in verse to the king, imploring him in respectful and loyal language to look with his own eyes to the miserable condition of his kingdom, was one day placed in his napkin on the royal table. Quevedo was denounced as the author (and no doubt he was, though his biographer, Dr de Tarsia, strives to disprove it), and was arrested at night and carried off to the convent of San Marcos at Leon, where, heavily ironed, he was lodged in a cell below the level of the river that washes the convent wall. He was soon struck down by an illness, brought on by cold and damp, from which he never recovered. He appealed to Olivares, but Olivares represented the king as implacable. In 1643, however, the count-duke fell from power, the ruthlessness of the king disappeared, and Quevedo was free to return to Madrid, broken in health and fortune; all his property within reach had been seized with his books and papers. He remained a year in Madrid, and then went home to La Torre to die; but the next year his sufferings became so acute that he had to move to Villanueva de los Infantes for medical aid, and there death released him in September 1645.

Quevedo was one of the most prolific Spanish poets, and was ranked by his contemporaries with Juan de Mena, Garcilaso, Lope, and Gongora; but he wrote no poetry for the world. His verses were all written for his friends or for himself, and, except those in the *Flores* of Espinosa (1605), the few pieces published in his life-time were printed without his consent. Poetry was with him a recreation and a solace, and, according to his nephew, some of his gayest and brightest verses were written in his cell at San Marcos. His poetry therefore is for the most part of an occasional character, and to a great extent made up of what would now be called *vers de société;* sonnets, serious and satirical, form a large portion of it, and light humorous ballads and songs a still larger. His more ambitious work is at times disfigured by conceits, but that it is the work of a true poet no one will dispute. All through life he was at war with the poets of the 'Culto' school, Gongora and his followers ('the scourge of silly poets' Cervantes called him), and this perhaps may have made him chary of appearing in public as a poet; but if he took no pains to place himself upon the roll of Spanish poets, he added to it the name of Francisco de la Torre, whose poems he discovered and published in 1631. It was for a long time maintained that the discovery was a pretended one; but it is now admitted that he could not have been the author. His place as a dramatist is not so well defined. About a dozen of his interludes are extant, but of his comedies, except two of which he was joint-author with Antonio de Mendoza, nothing is known. His prose is even more multifarious than his verse. His first book was a life of St Thomas de Villanueva in 1620 and his last, in 1644, a life of St Paul; and the greater part of his prose is of the same character, as is indicated by the titles: *The Patience and Constancy of Job, The Cradle and the Grave, Virtue Militant, The Martyrdom of Marcelo Mastrillo, Instruction how to Die, The Introduction to Devout Life,* from St Francis de Sales, and others of the same kind. Of his political works the *Politica de Dios* is the chief; but he also wrote a *Life of Marcus Brutus,* to which he was adding a second part when struck down by his last illness, a *Letter to Louis XIII.,* on the war of 1635, and several shorter tracts. In 1626, at Saragossa, his brilliant picaresque novel, the *Vida del Buscon Pablos,* or, as it was called after his death, the *Gran Tacaño,* was printed, apparently, like most of his books, without his permission, and at once took its place beside *Guzman de Alfarache;* and in 1627 his five *Visions,* four of which had been written between 1607 and 1610, and the fifth in 1621, were printed in the same way at Barcelona. His friend, Vander Hammen, immediately printed three of them at Saragossa from his own copies, and added the *Casa de los locos de Amor* ('The Madhouse of Lovers'), which has ever since been wrongly attributed to Quevedo. He himself disowned it; it bears no trace of his hand, and it is not printed as his by Vander Hammen, who, moreover, afterwards confessed himself the author. Chiefly for the sake of the vision or apologue of *Hell Reformed,* a sort of offshoot or sequel to the *Politica de Dios,* he wished the *Visions* to appear in an authorised edition at Madrid; but unluckily they were submitted for examination to the Padre Niseno, a friend of Montalvan, the dramatist, who had a grudge against Quevedo, and to obtain a license he had to consent to barbarous mutilations of his work which in some places make utter nonsense of it; and it is in this mangled shape the *Visions* have been printed ever since 1631. He added some short humorous pieces, on the affectations of the Culto school, the use of vulgar slang phrases, silly popular beliefs, and the like; and, the better to mask the design of the others, he called the volume *Juguetes de la Niñez* ('Playthings'), and apologised for the whole as the work of his youth, though the principal piece was written only three years back. The vision or apologue was Quevedo's favourite form of expression; his peculiar humour and satire are nowhere better seen than in *Fortuna con Seso* ('Fortune Right'), written in 1635, but not printed till 1650, in which Fortune demonstrates by experiment that if strict logic and justice took her place mankind would have a great deal more to complain of.

The edition of Quevedo's works in the *Biblioteca de Autores Españoles* (vols. xxiii. and xlviii., prose, edited by Aureliano Fernandez-Guerra; vol. lxix., verse, edited by Florencio Janer) is the only one that can be said to approach completeness. Many of the pieces in it are printed for the first time. The prose is edited with commendable thoroughness and industry; but Señor Fernandez-Guerra has unfortunately preferred the expurgated text of the *Visions* to that which came direct from the hand of Quevedo; he gives, however, the most important of the variations in his notes. The volume of verse is less satisfactory, and follows the stupid pedantic arrangement of the 17th-century editors. After Quevedo's death editions followed in quick succession, but most of them are slovenly in the extreme as regards editing, paper, and print. A handsome edition in 3 vols. 4to was issued by Foppens (Brussels, 1660–71), and well printed, if not critical ones by Ibarra (6 vols. 8vo, Madrid, 1772), by Sancha (11 vols. 8vo, Madrid, 1791–94), and by Castellanos (5 vols. 8vo, illustrated, Madrid, 1841–45); and an admirable selection (which in Quevedo's case is not only a defensible but a desirable form) was published by Villalpando (6 vols. 12mo, Madrid, 1798).

The earliest translations from Quevedo were into French by the Sieur de la Geneste, who translated the *Visions* in 1633, the *Hell Reformed* in 1634, and the *Vida del Buscon,* according to Barbier in 1633, or 1641 according to Brunet. His versions are by no means faithful or accurate, but they have the advantage of being based upon Quevedo's original text. From them most of the English versions have been made—e.g. *Visions; or Hel's Kingdome,* by R. Croshawe (1640); *Hell Reformed,*

by E. M. (1641); *Buscon, the Witty Spaniard*, by J. Davies (1657); and the well-known lively version of the *Visions* by Sir R. L'Estrange (1667). Captain John Stevens in 1697 produced a good translation from the original of *Fortuna con Seso*; and of the *Vida del Buscon* and some shorter pieces in 1707; and his translations, together with L'Estrange's *Visions*, were published in 3 vols. at Edinburgh in 1798 as *Quevedo's Works*. The best French translation of the *Vida del Buscon* is one by D'Hermilly under the title of the *Fin Matois* (1776), edited and by no means improved by Restif de la Bretonne. That by M. Germond de Lavigne is unfaithful. Led away by an absurd theory that Quevedo wrote the story when he was only fifteen, he has tampered with the text to make it suit his preposterous chronology. Under the title of *Voyages récréatifs de Quevedo* four of the Visions were very freely rendered by the Abbé Beraud in 1756. In 1648 Hans Moscherosch gave a still more free German version under the title of *Wunderliche Gesichte Philander's von Sittewald*; and in 1841 Dr Guttenstein treated the *Buscon* in much the same fashion in *Der Glücksritter*. An Italian translation of the novel by G. P. Franco appeared in 1634.

Quiberon, a small fishing-town of France (dept. Morbihan), at the extremity of a long narrow peninsula, 21 miles SW. of Vannes. Pop. 1036. It was here that a body of French emigrant royalists landed from an English fleet in 1795, and endeavoured to rouse the people of Brittany and La Vendée against the Convention, but were defeated and driven into the sea by General Hoche. Nearly all the prisoners taken were shot by order of the Convention. On 20th November 1759 Hawke completely defeated a French fleet under Admiral Conflans in Quiberon Bay.

Quichua, the language of the Indians of Peru (q.v.).

Quick, Robert Hebert, was born in 1832, had his education at private schools and at Harrow, whence he passed to Trinity College, Cambridge. He took orders, held curacies in Whitechapel and Marylebone, and was appointed by his college to the vicarage of Sedbergh in 1883, but four years later resigned the living. He had an intense love of children, and the great interest of his life was education. To the discussion of its theories he brought wide study, independent thought, and ripe wisdom; witness his bright and delightful *Essays on Educational Reformers* (1868; 2d ed. 1890). His practical knowledge of the work of teaching he had gained by service at Cranleigh, Harrow, and elsewhere. He died at Cambridge, 9th March 1891. See his Life by Storr (1899).

Quickens. See Couch-grass.

Quicksand (*quick*—i.e. 'living' or 'moving,' and *sand*), in its usual significance, a tract of sand which, without differing much in appearance from the shore of which it forms part, remains permanently saturated with water to such an extent that it cannot support any weight. Quicksands are most often found near the mouths of large rivers. They appear only to be formed on flat shores, the substratum of which is an irregular expanse of stiff clay or other impervious formation. Pools of water are retained in the hollows, and become partially filled with sand or mud, which remains like the soft sediment in a cup of cocoa on account of the absence of drainage. The sand on a uniform shelving shore consolidates at low tide because the water which permeates it drains back freely to the sea. In narrow channels through which the configuration of the adjoining shore causes strong tidal currents to run the sand may be kept so constantly stirred up by the moving water that a quicksand results. Thus, while the summit of a sandbank rising from a gentle slope is usually firm, the hollow margin of the bank where it meets the shore is frequently a quicksand. Quicksands are not commonly of great extent, and their danger has probably been exaggerated in the popular mind by sensational descriptions in works of fiction—e.g. in the *Bride of Lammermoor* and Wilkie Collins's *Moonstone*. Persons sink in a quicksand exactly as in water, only more slowly; and it is probable that if the victim did not struggle he would not sink over the head, as experiments show that water containing a quantity of solid matter in suspension has its floating power increased. It is a common belief amongst sailors that if a vessel is stranded on a quicksand it is inevitably sucked down. This cannot be the case unless the vessel springs a leak, or heels over sufficiently to let the semi-liquid sand enter. The idea may have taken rise from the popular association of quicksands with whirlpools, or from the fate of small vessels stranded at low tide on a stiff bank of clay which held them fast and allowed the rising tide to submerge them.

The name quicksand is sometimes applied, especially by old writers, to the drifting sands which are carried by wind over cultivated land bordering the seashore or a desert. See Downs, Drift, Dunes.

Quicksilver. See Mercury.

Quietism, a name given to a tendency shown at various periods in the history of the church by many classes of mystical religious enthusiasts, of widely different beliefs, to make perfection on earth consist in a condition of uninterrupted contemplation. In this state of quiet the soul ceases to reason, to reflect either on itself or God, or to form any of the ordinary acts of faith, its sole function being passively to receive the infused heavenly light which accompanies this state of inactive contemplation. The first of modern Quietists was the Spanish priest Molinos; its most famous devotee, Madame Guyon, whose gentle but powerful influence led into the same mode of thought the saintly Fénelon. Quietism has been called the Spanish analogue of Quakerism in England, of Jansenism in France, of Pietism in Germany; but these several systems, though they had common tendencies, were also sharply distinguished. It may be said that Quietism involves but little of practical consequence, whether for good or for evil. This may and does hold true in the case of noble and lofty souls like Fénelon; but what moved Bossuet and the church generally to strong opposition was the belief that, carried to its logical conclusion, Quietism led to Antinomianism, and would inevitably prove pernicious in its effects upon the vulgar crowd of followers. From the belief of the lofty and perfect nature of the purely passive state of contemplation there is, it was held, but a single step to the fatal principle in morals, that in this sublime state of contemplation all external things become indifferent to the soul, which is thus absorbed in God; that good works, the sacraments, prayer, are not necessary, and hardly even compatible with the repose of the soul; that so complete is the self-absorption, so independent is the soul of corporeal sense, that even criminal representations and movements of the sensitive part of the soul, and even the external actions of the body, fail to affect the contemplating soul, or to impress it with their debasing influence. See Bossuet, Fénelon, Guyon, Molinos; also Heppe, *Geschichte der Quietistischen Mystik in der Kathol. Kirche* (1875).

Quigrich. See Fillan (St).

Quilimane, a seaport of East Africa, in the Portuguese territory of Mozambique, stands about 15 miles from the mouth of the river of the same name, the northern arm of the Zambesi delta. The town occupies an unhealthy site, but imports cottons, beads, hardware, arms, coal, spirits, and food-stuffs to the annual value of £80,000, and exports ivory, ground-nuts, india-rubber, wax, copal, and oil-seeds to a value that ranges between

£90,000 and £160,000 a year. Fifteen per cent. of the total trade is for and from Nyassaland (q.v.). Pop. 6000, including 116 Europeans and 327 Asiatics.

Quillo'ta, a town of Chili, in the fertile valley of the Aconcagua, 13 miles from its mouth, and 25 miles by rail NE. of Valparaiso. Pop 9000.

Quills are the large feathers of the wings of birds, certain kinds of which have for centuries been used to make into writing-pens. From the swan, goose, and turkey the kinds are obtained that are regularly prepared for writing purposes, crow quills being used for drawing. A quill, like horn or hair, is formed of epidermic tissue, and the barrel or tube (the quill proper) has an external membrane and an internal pith. In order to get rid of these, and to bring the naturally soft state of the barrel into a condition ready for making into a pen, it requires to be dressed. The quill-dresser sits beside a fire enclosed with brick sides and with an iron face-plate in front, containing a hole somewhat larger than a crown piece. He first heats the quill by placing it for one or two seconds in this hole, which enables him to scrape off the outer membrane with a thick strong knife, the quill being pressed nearly flat in the operation. This done, he again holds it for a brief time in the furnace, by which the quill acquires the proper strength and brittleness to admit of its being made—by a knife or machine—into a pen with a clean slit. Quills were formerly prepared for writing by another process, which is still used for such as are made into toothpicks. This consists in steeping them for a night in water and then manipulating them in hot sand. Although the manufacture of quill-pens is a declining industry, they are still made in considerable numbers. The Controller of the Government Stationery Office, thinking the matter of some public interest, published between 1865 and 1873 a yearly statement showing the numbers of steel pens and quills supplied for the public service. These reports show that as late as the year 1868 there was still a large number of quills used. The figures for that year were: Quills, nearly 6000 gross, value £1816; steel pens, 14,942 gross, value £1900. These figures did not materially differ for the four previous years, but in 1873 the annual number of quills supplied had diminished by nearly one-half. In 1890 the quantities issued from the Stationery Office were: Quills, 4000 gross; steel pens, 38,000 gross.

Quiloa, or KILWA, a seaport of East Africa, in German territory, 190 miles S. of Zanzibar, and an outlet for the trade with Nyassaland, exports ivory, gum copal, rice, and manioc. Pop. 6000, including a number of Banyans.

Quilon, a town of Southern India, in the state Travancore, is situated on the west coast, 85 miles NW. of Cape Comorin. A settlement of the ancient Syrian Church and subsequently of the St Thomas Christians, it was, under the names Coilon and Columbum, a famous mart for the trade in timber, ginger, pepper, &c. The Portuguese built a fort there in 1503, which the Dutch took in 1653. From 1803 to 1830 it was garrisoned by the British. Pop. 13,588.

Quimper, a town of France (dept. Finistère), is prettily situated on the Odet, 11 miles from its mouth, and 63 miles by rail SE. of Brest. Its cathedral (1239–1515), a stately and richly-carved and ornamented edifice, is the principal building; there are also a college, a museum, and an agricultural school. Potteries are in operation, as well as tanyards, sailworks, &c.; and fishing is carried on. Pop. (1872) 13,159; (1891) 17,406.

Quin, JAMES, a celebrated actor, was born in London, of Irish descent, 24th February 1693, and made his first appearance on the stage in 1714 at Dublin. Shortly after he proceeded to London, where he was engaged at Drury Lane, but for quite inferior parts. In 1716, however, the sudden illness of a leading actor led to Quin's being called on to sustain the character of Bajazet in the once famous play of *Tamerlane*. His success was marked. Next year he exchanged Drury Lane for Rich's theatre at Lincoln's Inn Fields, where he remained as a principal actor for seventeen years. Not long after leaving the former place he had the misfortune to kill a brother-actor in a duel—a circumstance which clouded his reputation for a while. The only really fine parts which he seems to have played were Captain Macheath in the *Beggars' Opera* and Falstaff in the *Merry Wives of Windsor*. In 1734–35 he returned to Drury Lane Theatre, 'on such terms,' says Cibber, 'as no hired actor had before received;' and from this date until the appearance of Garrick in 1741 he was by universal consent the first actor in England. In 1746 Quin and Garrick acted together in the *Fair Penitent*, as a contest for pre-eminence. The novelty of seeing the two rival actors in the same tragedy, and the admirable acting of Mrs Cibber as the Fair Penitent, contributed greatly to the extraordinary success of this play. The superiority of Garrick was acknowledged by the best judges; and Quin, by no means pleased at his rising fame, sarcastically declared that 'Garrick was a new religion, and that Whitefield was followed for a time, but they would all come to church again.' In 1751 he withdrew from the stage, and fixed his residence at Bath, where he died, January 21, 1766. In society Quin was also popular, his conversation being full of wit and his stories amusing though coarse. He had a most benevolent heart, and among his many kind actions he was able on one occasion to do a great service to Thomson by delivering him from arrest, and afterwards lived 'in fond intimacy' with the poet, as Johnson tells us in his *Lives of the Poets*. An anonymous *Life of Quin*, dedicated to Garrick in 1766, was reprinted in 1887, with a supplement of corrections and additional information.

Quince (*Cydonia*), a genus of trees and shrubs of the natural order Rosaceæ, sub-order Pomeæ, nearly allied to Pyrus, with which many botanists have united it under the name *P. Cydonia*, but distinguished by having many instead of two seeds in each cell, and by their very mucilaginous nature. The Common Quince (*C. vulgaris*), a native of the south of Europe and temperate parts of Asia, is a low tree, with generally tortuous branches, ovate, entire, deciduous leaves, and rather large whitish flowers, which are solitary at the extremity of young branches. The fruit is in some varieties globose, in others pear-shaped, of a rich yellow or orange colour, with a strong smell. It is hard and austere, but when stewed with sugar becomes extremely pleasant, and is much used in this way either by itself or to impart a flavour to apple-pies. It is also much used for making a preserve called *Quince Marmalade*. A delicious beverage somewhat resembling cider is made from it. The seeds, which readily give out their mucilage to water, so that they turn forty or fifty times their amount of water into a substance as thick as syrup, have long been used in medicine. Quince mucilage or quince gum, *Cydonin*, is allied to Bassorin, but differs from it in being readily soluble in water (see GUM). The quince was cultivated by the ancient Greeks and Romans, and is at the present day cultivated in the south of Europe, in England, and generally in temperate climates. Its principal use in Britain

in a commercial sense is as a stock on which to bud or graft the pear. Many choice kinds of pear succeed better when united to it than when they are grafted on the true pear-stock. In Scotland the fruit seldom ripens except on a wall. The Japanese Quince (*C. japonica*, better known by its older name, *Pyrus japonica*), a low bush, a native of Japan, but perfectly hardy in Britain, is often to be seen trained against walls, being very ornamental from the profusion of its beautiful flowers, usually a rich red in colour. See Meech's *Quince Culture* (New York, 1888).

Flowering Branch of Quince (*Cydonia vulgaris*):
a, ripe fruit; *b*, section of do.
(Bentley and Trimen.)

Quincey, De. See De Quincey.

Quincy, (1) the third city of Illinois, and capital of Adams county, is on the Mississippi River, 160 miles above St Louis and 262 by rail SW. of Chicago. It is handsomely built on a high bluff, has a large trade by the river and extensive railway connections, an important railway bridge crossing the river at this point. The public buildings include a fine court-house, a medical college, several hospitals and asylums, an Episcopal cathedral, and some forty other churches. The city has many large flour-mills, machine-shops, foundries, saw- and planing-mills, breweries, and manufactories producing stoves, furniture, carriages, tobacco, &c. Pop. (1880) 27,268; (1890) 31,494.—(2) A town of Massachusetts, near the sea, and 8 miles S. of Boston by rail. The township produces the famous Quincy granite, and was the birthplace of John Hancock, John Adams, and his son, John Quincy Adams. Pop. (1880) 10,570; (1890) 16,723.

Quincy, Josiah, an American orator and man of letters, and son of Josiah Quincy (1744–75), an eloquent advocate of the rights of the colonists, was born at Boston, February 4, 1772, graduated at Harvard in 1790, and was called to the bar in 1793. He took an active interest in politics as a leading member of the Federal party in New England, and was elected in 1804 to congress, where he became distinguished as a ready, earnest, and fervent orator. He was one of the earliest to denounce slavery, but his most remarkable speech was one in which, spurred on by the jealousy with which the old New England colonies regarded the new western states, he declared that the admission of Louisiana would be a sufficient cause for the dissolution of the union, and that, 'as it would be the right of all, so it would be the duty of some, to prepare definitely for a separation—peaceably if they could, violently if they must.' Disgusted with the triumph of the Democratic party and the war of 1812, he declined a re-election to congress, and devoted his attention for a while to agriculture. He was, however, a member of the Massachusetts legislature during most of the next ten years, served as mayor of Boston from 1823 to 1828, and in 1829 accepted the post of president of Harvard, which he held until 1845. His remaining years were spent in quiet literary work, and he died at Quincy, July 1, 1864. Among his published works are Memoirs of his father (1825) and of J. Q. Adams (1858), and histories of Harvard University (1840), of the Boston Athenæum (1851), and of Boston (1852). His *Speeches* were edited (1874) by his son, Edmund Quincy (1808–77), who was secretary of the American Anti-slavery Society, and contributed largely to the Abolitionist press.

Quinet, Edgar, a great French writer, was born of an old Catholic family at Bourg in the department of Ain, February 17, 1803. His mother, whose dreamy and emotional nature he inherited, was a Protestant. In 1806 the child was carried by his mother to join his father, then Commissioner of the Army of the Rhine, and he spent great part of his boyhood in the remote and dreary solitudes of Certines near Bourg. His parents were both ardent republicans, hating the very name of Napoleon. Accordingly the boy early made him a hero in his heart; but as he grew up a passion for liberty superseded his first love. He was educated at the colleges of Bourg and Lyons (1817–20), and next went to Paris; but refusing to take the course for a soldier at the École Polytechnique, he published in justification of his choice of a profession *Les Tablettes du Juif Errant* in 1823. He found the spiritual impulse that he needed in an English translation of Herder's *Philosophy of History*, and this he determined to translate into French, although he had first to learn German to do so. He published the book in 1825, and his remarkable Introduction procured him the friendship of Cousin, at whose house he met Michelet, for fifty years the 'brother of his heart and mind.' He had already travelled in Germany, Italy, and England, when in 1829 he was appointed to a post on a government mission to Greece. The fruit of his travels was *La Grèce Moderne* (1830). A speculative republican of ideas, one of the earliest writers for the *Revue des Deux Mondes*, and a student before their time of the old Chansons de Geste, Quinet played a conspicuous part in the Paris of his day, and made his name known beyond its walls by his *Ahasvérus* (1833), a kind of spiritual imitation of the ancient mysteries, in which the Wandering Jew stands as an emblem of humanity in its hopeless groping for certainty and rest. In 1834 he married, and next produced his less successful poems, *Napoléon* (1836) and *Prométhée* (1838). These three works fall naturally into a kind of trilogy, in which Ahasuerus represents the race, Napoleon the individual, and Promethens the martyr, typical of the religious leader. In 1838 he published his *Examen de la Vie de Jésus*, in which he shows that Strauss is too analytic to detect the true principle of life in the gospels. Quinet's deepest conviction was that religion is the very substance of humanity, that the true founders of society have been teachers like Zoroaster and Moses, and that Christianity itself is the apotheosis of personality.

Appointed in 1839 professor of Foreign Literature at Lyons, he began those lectures which afterwards formed his brilliant book, *Du Génie des Religions* (1842). He was now recalled to Paris to the chair of 'Littératures Méridionales' at the Collége de France, and here for four years he lectured to a crowd of enthusiastic disciples on such themes as the revolutions in Italy, the Jesuits, Ultramontanism, and Christianity in relation to the French Revolution. He joined Michelet in attacking the Jesuits, and his epigrammatic eloquence, added to the enthusiasm and earnestness of his convictions,

made the blow he struck the order the deadliest it had received in France since the days of Pascal. But his lectures caused so much excitement that government suppressed them in 1846. Next came the Revolution, in which Quinet took his place on the barricades, and after its success was elected to represent Ain in the National Assembly, where he voted in the Extreme Left. He was little of a practical statesman, but from the beginning he saw the traitor under the mask of Louis Napoleon. After the *coup d'état* he was exiled to Brussels, whence in 1857 he migrated to Veytaux on the shores of the Lake of Geneva. His mother had died in 1847, his wife in 1851, and soon after his exile he married the daughter of a Roumanian patriot, Georges Asaky. At Brussels he produced *Les Esclaves* (1853), and an edition of the chief writings of Marnix de Ste Aldégonde (1856); and in Switzerland *Merlin l'Enchanteur* (2 vols. 1860), a book of enormous rhetorical power, lofty but ill-sustained thought, and dazzling imagery. Other works were *La Révolution Religieuse au XIX.e Siècle* (1857); *Histoire de mes Idées* (1860), a delightful fragment of an autobiography; *Histoire de la Campagne de 1815* (1862), in which he showed that Napoleon's fall was due to his own outrage upon righteousness alone; *La Révolution* (1865), in which he demonstrated that its frightful crimes were the fruit of the suspicions and mistrust begotten by twelve centuries of despotic education. All the disasters of French history he traced to the national denial of righteousness in the Revocation of the Edict of Nantes; the Terror was the direct result of St Bartholomew and the Dragonnades, and again was itself the parent of the 18th Brumaire and the 2d December. After the downfall of Napoleon III. he returned to Paris, and during the siege strove to keep aglow the expiring fire of patriotism. He sat in the National Assemblies at Bordeaux and Versailles, and aroused great enthusiasm by his impassioned if somewhat vague orations. He died at Versailles, 27th March 1875.

Quinet's latest books were *La Création* (1870), a characteristically bold and imaginative incursion into the domain of science; *La République* (1872); and *L'Esprit Nouveau* (1874). *Le Livre de l'Exilé* appeared posthumously. His wife published in 1870 *Mémoires d'Exil;* his *Correspondance Inédite* followed in 1877 (2 vols.), his *Lettres d'Exil à Michelet et à Divers Amis* in 1884-86 (4 vols.). An edition of his *Œuvres Complètes* in 26 vols. (1857-79) was prepared by an influential committee as a national tribute of respect to the poet, the prophet, and the patriot. See the biography by Chassin (1859); *Edgar Quinet depuis l'Exil* (1889), by his widow; Richard Heath's *Edgar Quinet: His Early Life and Writings* (1881); also the essays by Professor Dowden in *Studies in Literature* (1878), and E. Montégut in *Mélanges Critiques* (1879).

Quinine is an alkaloid having the chemical formula $C_{20}H_{24}N_2O_2,3H_2O$. Along with cinchonidine, cinchonine, and a large number of other alkaloids, it is present in the bark of numerous species of Cinchona and Remijia, of which these substances constitute the active medicinal principles. Good barks yield an average of 5 to 6 per cent. total alkaloids, of which one-half is quinine and cinchonidine, the other half consisting of the other alkaloids in varying proportions. Quinine is by far the most important from a medical and commercial point of view; the yield of it varies greatly, $1\frac{1}{2}$ and 8 per cent. being the extremes. Quinine is obtained from the powdered bark by treating it with lime, and then extracting the mixture with alcohol, neutralising with an acid so as to obtain a salt of quinine, and finally purifying the product. In 1820 Pelletier and Caventou isolated pure quinine, and demonstrated that it was the chief active ingredient in the bark. Many attempts have since been made to prepare it artificially, but without success. For the introduction of the bark into Europe, and the culture of the tree in South America and (recently) in India, see CINCHONA.

Quinine itself is not used in medicine, owing to the inconveniences arising from its insolubility in water, but many of its salts are, and two of them, the sulphate and hydrochlorate, are included in the British Pharmacopœia along with numerous preparations of cinchona-bark containing them. The sulphate is the most commonly used preparation, and it is popularly known as quinine. It occurs in small, silky, snow-white crystals, which have a purely and intensely bitter taste, and are sparingly soluble in water (1 in 700 parts); its solutions have a bluish or fluorescent colour even when very dilute. In alcohol or dilute sulphuric acid it is very soluble. The hydrochlorate closely resembles the sulphate, but is much more soluble in water (1 in 34 parts), and its solutions are not fluorescent. When treated with excess of chlorine water and a few drops of ammonia solution, solutions of quinine give a clear emerald green colour; if ferrocyanide of potassium be added this changes to a ruby red.

Preparations of quinine, and especially the sulphate, are very largely used in medicine. Locally applied dilute solutions (2 to 4 gr. to the oz. of water) have a germicidal, antiputrefactive, and antifermentative action, hence they are used as lotions in hay fever, diphtheria, cystitis, and similar diseases. As a bitter tonic small doses ($\frac{1}{2}$ to 2 grains) are frequently given in general debility, atonic dyspepsia, anæmia, scrofula, convalescence from acute diseases, and other conditions where tonic treatment is required. It is also of great value as an antipyretic and antiperiodic. In healthy persons it does not reduce the bodily temperature, but in typhus, typhoid, rheumatic, and some other fevers it is extremely valuable in this respect. A dose of 3 to 15 grains may be given in these cases. In certain fevers it does not reduce temperature. In malarial affections of all kinds it is supreme, and at present no other known drug can compare with it in efficacy. In intermittent fevers and ague the best plan is to begin its administration about eight hours before the attack is expected, and continue it in hourly doses for three or four hours until 15 to 30 grains have been given. It cuts short or aborts the recurring febrile attacks. It is also of great value as a prophylactic in persons who are exposed to the risks of malarial poisoning. In such cases three grains twice daily is usually considered a sufficient dose.

Quinine is also largely given in neuralgia and in inflammations. Large doses are very apt to irritate the stomach, and sometimes produce a train of symptoms known as cinchonism. There is singing in the ears, dizziness, deafness, a feeling of fullness in the head, and disturbance of vision—all of which usually pass off without leaving any ill results. In some cases the effects are more severe, and may lead to dangerous depression and collapse, especially if the patient be already weakened by disease. Certain persons are very susceptible to the action of quinine, and suffer from cinchonism after small doses. In others skin eruptions, œdema of the face, irritation of the bladder and kidneys, and other disagreeable effects are sometimes seen. Workers in quinine-factories also occasionally suffer from skin eruptions. These accidents are, however, comparatively rare.

The sulphate of cinchonidine and sulphate of cinchonine are also included in the British Pharmacopœia. They have the same actions and uses as quinine, but are very much less used. They seem, however, to be efficacious, and are cheaper.

See works by J. E. Howard (1876), C. R. Markham (1880), Manson (1882), and Flückiger (1884).

Quinoa (*Chenopodium Quinoa*), a valuable food-plant, a native of Chili and the high table-land of Mexico, which much resembles some of the British species of Chenopodium (q.v.). In the countries in which it is indigenous it is much cultivated for its seeds, which form a principal food of the inhabitants. The meal made from some varieties of the seed has a somewhat peculiar flavour, but it is very nutritious and is made into a kind of porridge and cakes. The plant is sometimes cultivated in British gardens for its leaves, which are a good substitute for spinach.

Quinoline, a pungent colourless liquid obtained by the distillation of bones, coal-tar, and various alkaloids. It is the base of many organic bodies, and is isomeric with Leucol (q.v.).

Quinquagesima (Lat., 'fiftieth'), the Sunday immediately preceding Ash-Wednesday. The common explanation of the name Quinquagesima, and of Sexagesima and Septuagesima, the two preceding Sundays, is that the Sundays are, roughly speaking, about fifty, sixty, and seventy days respectively before Easter. Quinquagesima, indeed, is exactly fifty days before the Octave of Easter—i.e. Low Sunday (q.v.). But probably the terms were adopted without any intention of expressing definite numbers, and simply on a false analogy with Quadragesima, the Latin name of Lent.

Quinqueremes, vessels with five banks of oars, however arranged (see TRIREME), may be regarded as the first-rates of the ancient navies.

Quinsy (originally *squinancy;* Fr. *esquinancie;* from Gr. *kynanchē*), known also as *Cynanche Tonsillaris* and *Tonsillitis*, or as 'inflammatory sore throat,' is an inflammatory affection of the substance of the tonsils, attended when fully developed by suppuration (see PALATE). The inflammation is seldom limited to these glands, but extends to the uvula, the soft palate, and the pharynx. The disease usually manifests itself by difficulty in swallowing, and a sense of heat and discomfort in the throat, often amounting to considerable pain. On examination the throat at first exhibits unnatural redness, with enlargement of one or both tonsils. The uvula is enlarged and elongated, its end either dropping down into the pharynx, and, by exciting the sensation of a foreign body, giving rise to much irritation, or else adhering to one of the tonsils. The tongue is usually furred, and the pulse rapid, and there are the ordinary symptoms of that form of constitutional disturbance known as inflammatory fever. The inflammation terminates either in resolution (if the attack is not severe, and yields readily to treatment) or in suppuration, which may be detected by the occurrence of slight rigors, and by the increased softness of the enlarged tonsil. The matter which is discharged has sometimes a very fetid smell, and the fetor may be the first indication of the rupture. The pain almost entirely ceases with the discharge of matter, and recovery is then rapid. The disease usually runs a course of from three to seven days; but it may be prolonged if, as sometimes happens, the two sides are successively affected. It almost invariably terminates favourably. It is most common between the ages of fifteen and twenty-five. The ordinary exciting cause of this disease is exposure to cold, especially when the body is warm and perspiring; and certain persons (or even families) are so subject to it that slight exposure is almost sure to induce it.

The patient should remain in the house (or, in cold weather, even in bed), and should be kept on low, non-stimulating diet. According to Sir Morell Mackenzie, the best treatment at the commencement of the attack consists in the administration of guaiacum. He gives it in the form of lozenges, each containing three grains, and one to be sucked every two hours, and states that by this means the disease may generally be averted. Baking-soda (bicarbonate of soda) applied to the affected part on the tip of the forefinger every hour or half-hour often has the same effect. In more severe cases the patient may gargle frequently with hot water, or may inhale the vapour of boiling water, and apply hot poultices or fomentations to the side of the neck. Blistering and leeching will sometimes give relief, but if suppuration is once established they do harm rather than good. If the tonsils are very much enlarged they should be pricked with a lancet to let out the pus.

Quintain was an instrument used in the ancient practice of tilting on horseback with the lance. It consisted of an upright post, surmounted by a cross-bar turning on a pivot, which had at one end a flat board, at the other a bag of sand. The object of the tilter was to strike the board at such speed that he would be well past before the bag of sand, as it whirled round, could hit him on the back. At Offham in Kent, 7 miles WNW. of Maidstone, there are the remains of an old quintain; and at the May games held at St Mary Cray in Kent, near Bromley, in 1891 the quintain was also revived.

Quintal, a French weight corresponding to the English 'hundredweight,' was equal to 100 pounds (livres); on the introduction of the metrical system the same name was employed to designate a weight of 100 kilogrammes (see GRAMME). The metrical quintal, equivalent to 220 lb. avoirdupois, is thus more than twice as heavy as the old one.

Quintana, MANUEL JOSÉ, whose patriotic odes obtained for him the surname of the 'Spanish Tyrtæns,' was born at Madrid, 11th April 1772, studied at Salamanca, and established himself as an advocate in his native city, where his house became a resort of the advanced liberals of the time. Besides his Spanish Plutarch (*Vidas de los Españoles Celebres*, 1807–34), a work which is reckoned one of the finest Spanish classics, he published one or two tragedies, and an excellent selection of Castilian poetry. On the restoration of Ferdinand VII. in 1814 Quintana's liberalism caused his imprisonment for six years; but he ultimately forsook the liberal cause, held office, and died 11th March 1857.

Quintett, a musical composition for five solo voices, or for five instruments, each of which is *obligato*. Quintetts for strings have been written by Boccherini, Beethoven, Mendelssohn, Schubert, Onslow, &c.; for other combinations of instruments, generally including the pianoforte, by Mozart, Schubert, Schumann, Brahms, and Raff. Of vocal quintetts one of the most notable is that in Wagner's *Meistersinger*.

Quintilian. M. Fabius Quintilianus was born about 35 A.D. at Calagurris (*Calahorra*), in Spain, and attended in Rome the prelections of Domitius Afer, who died in 59. After this date, however, he revisited Spain, whence he returned in 68 to Rome, in the train of Galba, and began to practise as a pleader in the courts, in which capacity his reputation became considerable. He was more distinguished, however, as a teacher than as a practitioner of the oratorical art, and his instructions came to be the most eagerly sought after among all his contemporaries, his pupils including Pliny the Younger and the two grandnephews of Domitian. As a mark of this emperor's favour he was invested with the insignia and title of consul; while he also holds the distinction of being the first public teacher who benefited by the endowment of Vespasian, and received a fixed salary from the imperial

exchequer. His professional career as a teacher of eloquence commenced probably about 72, but after twenty years of labour as advocate and teacher he retired into private life, and died probably soon after 96. His reputation rests securely on his great work entitled *De Institutione Oratoria Libri XII.*, a complete system of rhetoric, which he dedicates to his friend Victorius Marcellus, himself a court favourite and orator of distinction. It was written—as he tells us in his preface to his publisher Trypho—after he had ceased to be a public teacher, and was the fruit of two years' labour. In the first book he discusses the preliminary training through which a youth must pass before he can begin those studies which are requisite for the orator, and he gives us an elaborate outline of the mode in which children should be educated in the interval between the nursery and the final instructions of the grammarian. The second book treats of the first principles of rhetoric, and contains an inquiry into the essential nature of the art. The subjects of the five following books are invention and arrangement; while that of the eighth, ninth, tenth, and eleventh is style (*locutio*), with memory and delivery. Of these the eighth and ninth discuss the elements of a good style; the tenth, the practical studies requisite; the eleventh, appropriateness, memory, and delivery. The last, and in the author's view most important, book is devoted to the various requisites for the formation of a finished orator, such as his manners, his moral character, his mode of undertaking, preparing, and conducting causes, the style of eloquence most advantageous to adopt, the age at which pleading should be begun, and at which it should be left off, and other allied topics. The entire work is remarkable for its sound critical judgments, its purity of taste, admirable form, and the perfect familiarity it exhibits with the literature of oratory. The condensed survey of Greek and Roman literature with which the tenth book commences has always been admired for its clearness, width of intellectual sympathy, and vigour. Quintilian's own style is excellent, for though he is not free from the love of florid ornament and poetic metaphor characteristic of his age, he was saved from its extremes by his good sense, which refused to sacrifice clearness and simplicity to effect, and still more, by his wholesome admiration for Cicero. The style of Seneca he discusses almost as fully as he does that of Cicero, denouncing it as a dangerous model for the orator to follow. He makes an obvious effort to be fair in balancing his praise and blame, but a careful reader detects an undertone of dislike, whether to Seneca's philosophy or his person. Nineteen longer and 145 shorter *Declamations* (ed. C. Ritter, 1885), which have been ascribed to him, are now believed to be spurious, as they evidently belong to different authors, and even different epochs.

The best edition of Quintilian's works is that of Burmann (1720); of the *Institutio Oratoria*, those by Spalding, completed by Zumpt and Bonnell (1798–1834), the last volume (vi.) containing a lexicon, Halm (1868–69), and the hand-edition by Meister (1886–87). Of Book x. alone there are editions by Professor J. E. B. Mayor (1872, incomplete), Hild (Paris, 1885), Frieze (New York, 1889), and Principal Peterson (Oxford, 1891). There are English translations by Guthrie (1805) and the Rev. J. S. Watson (Bohn, 1855–56). See Karl Pilz, *Quintilianus: ein Lehrerleben aus der romischen Kaiserzeit* (1863), and C. Ritter, *Die Quintilianischen Declamationen* (1881).

Quintus Curtius. See CURTIUS.

Quipu, the language of knotted cords which was used by the Incas of Peru previous to the conquest of their country by the Spaniards. A series of knotted strings was fastened at one end to a stout cord; the other ends hung free. This was used for the purpose of conveying commands to officers in the provinces, and even for recording historic annals. The colours of the strings and the order of their arrangement, the character and number of the knots, their distance from the cord to which they were connected, and the methods of their interlacing were the principal elements in this 'knotty language.'

Quirinus (see MARS).—The QUIRINAL (Lat. *Collis Quirinalis*) is one of the seven hills of ancient Rome (q.v.), and next to the Palatine and Capitoline the oldest and most famous quarter of the city. For *Quirites*, also, see ROME.

Quiscalus. See GRAKLE.

Qui Tam actions are actions so called in the law of England from the first words of the old form of declaration by which informers sue for penalties, the plaintiff describing himself as suing as well for the crown as for himself, the penalty being divided between himself and the crown.

Quitch. See COUCH-GRASS.

Quito, the capital of Ecuador, and of the province of Pichincha, lies in 0° 14′ S. lat., on the east side of the great plateau of Quito, at the foot of the volcano of Pichincha (q.v.), at an elevation of 9351 feet above the sea. Its site, cut up with numerous ravines, is very uneven; but the streets are laid out regularly at right angles, plunging into and scaling the sides of the valleys which come in their course. The city is well paved, but the sidewalks are very narrow; and the streets are lit only with candles or kerosene lamps—oftenest those placed before shrines at the street-corners. The appearance of Quito is very picturesque, and its beautiful environment of mountains, together with its clear, healthy, and temperate climate, maintaining an eternal spring, renders it one of the most charming cities of South America; yet the abrupt changes from the hot sun of mid-day to the chills of evening make pneumonia and diseases of the chest very common. The chief edifices are built of stone, the others of adobes or sun-dried bricks, covered with tiles. In the great square stand the quaint cathedral, with its green-tiled dome, the archbishop's palace, the municipal building, and the capitol, built of brick and stucco, with wine-shops on the ground-floor and the two halls of congress on the third story. Other public buildings include the university, a seminary, an institute of science, an observatory, a museum, a library of 20,000 volumes, a penitentiary with 500 cells, a hospital with 500 beds, a lunatic asylum, a retreat for lepers, a score of churches, and three times as many monasteries. Most of these last are in a very dilapidated condition, for which it is hard to find any explanation but laziness; for they still retain their lands and revenues, and the offerings of the faithful, who are nearly all Indians, are as constant as ever. Indeed, Quito is the paradise of priests—of whom there are more than 400 in the city—and the bells are jangling all day long; for Ecuador is the most faithful province of the pope, and the one state in the world which still refuses to recognise the unity of Italy and the condition of affairs that resulted from the occupation of Rome. There are only two or three good shops, and no hotels; the daily market in the square before the monastery of San Francisco is the general purchasing-place, and the religious houses serve for hostels. The city boasts a telephone system, but water is still purveyed in great jars borne on the shoulders of carriers. The manufactures include cottons and woollens and beer; the drying of bird-skins (humming-birds'), the copying of religious paintings, and the production of images of the Virgin and of saints rank as important industries. Founded in 1534, Quito has suffered frequently

from earthquakes (especially in 1797 and 1854) and from revolutions (recently in 1877 and 1883). Pop. about 50,000, mainly Indians and mestizoes. See Monnier, *Des Andes au Para* (1890); also Vincent, *Around and About South America* (1890).

Quit Rent, a term used to denote various nominal rents; properly speaking, a quit rent is a rent reserved in lieu of all services, because on paying it the holder of the land goes quit and free. In old records it is called white rent, because it was paid in silver money, as distinguished from corn rents. The Conveyancing Act, 1881, empowers an owner of land to redeem any quit rent to which it may be subject.

Quoad Sacra. See PARISH.

Quoin (Fr. *coigne*, from Lat. *cuneus*) is generally a wedge or an angle. In artillery the quoin is a wedge inserted beneath the breach of a gun, for raising or depressing the muzzle. Quoin, in Architecture, is one of the stones forming the solid corner of a building. Where the work is of brick or small materials the quoins are usually of ashlar.

Quoits, a game much practised in many districts of Great Britain, seems to have been derived from the ancient game of 'throwing the *discus*,' which was such a favourite amusement of the Greeks and Romans. The discus was a circular plate of stone or metal, 10 to 12 inches in diameter, and was held by its farther edge with the right hand, so as to lean upon the forearm, and was cast with a swing of the arm, aided by a twist of the whole body. It was generally thrown edge foremost, and upwards at an angle of 45°, so as to give it as great a range as possible, and the player who threw it farthest was the winner. Sometimes a kind of quoit was used. The modern game of quoits differs very considerably from this. A quoit is a flattish ring of iron, generally about 8 inches in external diameter, and between 1 and 2 inches in breadth; the weight accordingly varies a good deal, but may in any match be fixed beforehand. The quoit is convex on the upper side, and slightly concave on the under, so that the outer edge curves downwards, and is sharp enough to stick into the ground. The mode of playing is as follows: Two pins, called 'hobs,' are driven into the ground from 18 to 21 yards apart; and the players, who are divided into two parties, stand at one hob, and in regular succession throw their quoits (of which each player has two) as near to the other hob as they can. The points are counted as in bowls or in curling. To facilitate the sticking of the quoits at the point where they strike the ground, a flat circle of clay—about 1 or 2 inches in thickness, and 1½ feet in radius—is placed round each hob; this requires to be kept moist. The quoit, when to be thrown, is grasped with the right hand by one side, and pitched with an upward and forward jerk of the hand and arm, which give it a whirling motion, and cause it to strike the ground with its edge. Players acquire such dexterity in this game that they can very frequently 'ring' their quoit—that is, land it so that the quoit surrounds the hob.

Quorn, or QUORNDON, a village of Leicestershire, 2½ miles SE. of Loughborough, gives name to a celebrated kennel (and hunt) of foxhounds. Pop. 1816. See FOXHUNTING.

Quorra. See NIGER.

Quorum is a legal term denoting a certain specified number out of a larger number as entitled or bound to act for certain purposes. Thus, in statutes appointing commissioners or trustees of a public work it is usual to name a certain number of the whole body as sufficient to discharge the business when it may be inconvenient for all to attend. For the origin of the expression, see JUSTICE OF THE PEACE, Vol. VI. p. 378.

Quotidian Fever. See AGUE.

Quo Warranto, the title of a writ by which a person or corporate body is summoned to show by what warrant a particular franchise or office is claimed. In the reigns of Charles II. and James II. the writ was used oppressively, for the purpose of depriving cities and boroughs of their liberties. At the present day an information in the nature of a quo warranto may be filed, with the leave of the court; disputed questions in regard to municipal offices, &c. are sometimes brought to trial in this way. The information is now regarded as a form of civil process.

Qurân. See KORAN.

R

is the eighteenth letter in our alphabet. In ancient Egyptian there seems to have been no clear distinction between the sounds of *r* and *l*, both of which are liquid trills, the breath escaping over the vibrating edges of the tongue—in the one case over the tip, in the other over the sides (see L). Consequently the hieroglyphic picture of the 'lioness,' from which our letter *l* is derived, was used almost interchangeably with the picture of the mouth (see ALPHABET), which became the source of the letter *r*. But the Semites, who obtained their alphabet from the Egyptians, made a clear distinction between the two sounds, and hence the two Egyptian symbols were specialised, the tailed hieratic form of the Egyptian picture of the mouth being exclusively adopted as the Semitic sign for *r*. It was called *resh*, 'the head,' because in the hieratic form, 9, it resembled the oval of the head supported on the neck. In the lapidary writing of the Phœnicians the letter became angular instead of rounded, and the Semitic form, 4, passed without alteration into the earliest Greek alphabet. When the direction of the Greek writing was reversed the form was somewhat rounded, giving for the sound of *r* the symbol P, which was called *rhō*. The Semitic name *resh* or *rhos* would become *rhosa* in Greek, but as in Greek an *s* normally disappears between two vowels, this would give *rhoa*, and finally *rhō*, owing to the coalescence of the vowels. In the primitive Greek alphabet, as in the Phœnician, the forms of the signs for *b*, *d*, and *r* differed little, and confusions arose. Hence the signs were differentiated in various ways. In the early Greek alphabet which found its way into Italy the tail of P was curved round, giving the form B with a lower loop, to denote *b*, while for *d* the tail was shortened and finally disappeared, giving D. For *r* a short tail was added, giving the form R, which ultimately became R, while the form P was retained to represent *r* in the Eastern alphabet and in the Western to represent *p*. The tail of R began to make its appearance in the Greek alphabet before it was transmitted to Italy, but subsequently disappeared, other ways of avoiding the confusion between the forms having been invented. For the lapidary and capital forms the old R has been retained, but in minuscule writing we use r and ɾ, the first of which is an uncial form derived from R; the second, called the *r rotunda*, coming from the old Roman cursive, in which the vertical stroke of R has nearly disappeared, being represented only by the small tag at the top of ɾ.

The sound of *r* is a true consonant in the north of England, where it is exaggerated in the Northumberland burr. In Sanskrit it is vocalic; in the south of England it is often reduced to a semivowel or even to a vowel; while in the Midlands, in Scotland, and in France it preserves the proper sound of a trilled liquid which it had in Latin and Anglo-Saxon. After a guttural vowel it is hardly heard, *farther* being now almost indistinguishable from *father*. The Irish *r* is a survival of the old English sound, the pronunciation *harum* for 'harm,' *arum* for 'arm,' and *borcn* for 'born,' reproducing, it is believed, the mediæval English sound, which is now less resonant than it formerly was. The sounds of *r* and *l* are often interchanged. In the Indian alphabet the Semitic symbol for *r* represents *l*, and the symbol for *l* represents *r*. The Japanese sign for *r* was obtained from a Chinese sign for *l*, and some Polynesian and South African peoples replace *r* by the easier sound of *l*, as is also done by English children, who, however, often prefer *w*, saying *wewy* for 'very.' The sound of *r* is usually the last which children learn to pronounce. In English *l* frequently replaces *r* and occasionally *r* replaces *l*, as in 'turban' from *tolibant*. Sometimes *r* disappears, as in 'speak' from O.E. *sprecan*, 'pin' from O.E. *preon*, 'palsy' from O. Fr. *paralysie*, and 'cockade' from O. Fr. *cocart*. It is intrusive in 'shrill' from O.E. *schill*, in 'hoarse' from O.E. *hós*, in 'partridge' from Lat. *perdix*, in 'cartridge' from Fr. *cartouche*, in 'corporal' from Fr. *caporal*, and in 'culprit' from Lat. *culpa*. It is also intrusive in *iron* and bride-*groom*. There is a modern tendency to insert a final *r*, as in 'taters' for 'potatoes' and 'Victoriar' for 'Victoria.' In the words *our*, *your*, *their*, *her*, the *r* is a survival of an old genitive suffix. Sometimes *r* is transposed, as in 'horse' from *hross*. In Latin *r* supplants *s* between two vowels and sometimes at the end of words, as in 'arena' for *ascna*, 'dari' for *dasi*, 'plurima' for *plusima*, 'honor' for *honos*, 'arbor' for *arbos*.

Ra. See EGYPT, Vol. IV. p. 234.

Raab (Hung. *Győr*), a town of Hungary, stands on an extensive plain at the confluence of the Raab and the Little Danube, a branch of the great river of that name, 67 miles WNW. of Buda-Pesth. It contains numerous religious edifices, among which is a beautiful cathedral. The manufactures are chiefly tobacco and cutlery. Pop. 22,981.

Raalte, a town of the Netherlands, in the province of Overyssel, 11 miles NNE. of Deventer. Pop. 5795.

Raasay, one of the Inner Hebrides, lies between the Isle of Skye and the mainland of Scotland, and belongs to Inverness-shire. It is 13 miles in length from north to south, 3½ miles in greatest breadth, and 24 sq. m. in area. Pop. (1841) 647; (1891) 438. The western side of the island is bare and uninteresting. On the eastern and more sheltered side there is some striking scenery. Dun Caan (1456 feet) is the highest point, and Brochel Castle, on the east shore—now a mere ruin—the chief object of interest.

Rabanus Maurus (or more correctly *Hrabanus*), a great Carolingian churchman and divine, was born of noble parents at Mainz about 776, and had his education at Fulda and at Tours under Alcuin, who surnamed him Maurus after the favourite disciple of St Benedict. He was next placed at the head of his school at Fulda, where he trained scholars like Walafrid Strabo and Otfrid of Weissenburg. In 822 he became abbot, but resigned in 842 to retire to the neighbouring cloister of Petersberg, whence in 847 he

was called to the archbishopric of Mainz. The chief event of his reign was his severity against the too logical monk Gottschalk for his views on predestination. He died in 856. His writings show erudition but little originality. They include Commentaries on the Old Testament, St Matthew, and St Paul's Epistles, homilies, doctrinal treatises, hymns, and a Latin-German glossary to the Bible (Graff's *Diutiska*, vol. iii.). Among these are *De Institutione Clericorum*, and *De Universo Libri xxii., sive Etymologiarum Opus*, a kind of encyclopædia of its time.

His *Opera Omnia* (so called) fill vols. cvii.–cxii. of Migne's *Patrologiæ Cursus Completus*—a reprint of the Cologne edition of Colvenerius (6 vols. folio, 1627), to which are prefaced the *Lives* by his disciple Rudolphus and by Joannes Trithemius. See the studies by Spengler (1856), Köhler (1870), and Richter (1882).

Rabat, also called NEW SALLEE, a seaport of Morocco, and one of the most picturesque towns of the empire, is situated on the south side of the Bu-Ragreb, at its entrance into the Atlantic. It stands on cliffs in the midst of gardens, and is overlooked by a large citadel. The most conspicuous object is, however, the tower of Beni-Hassan (180 feet high), rivalling the great towers of Seville (Giralda) and Morocco (Kutubiya); near it is the ruined mosque of Almanzor, originally intended to be made the largest in the world. Ruins still exist of the sultan's palace that was immortalised by the feats of Dick Whittington's cat. Carpets, shoes, and mats are made, and woollens dyed. But, owing to the silting up of the mouth of the river, the commerce of Rabat has much declined. Formerly it was the centre of the European trade with Morocco; it still exports olive-oil, grain, hides, flax, wool, maize, and millet. There is a small import of cotton-stuffs, sugar, candles, and tea. Pop. 26,000. See *English Illustrated Magazine* (February 1890); also SALLEE.

Rabbi (Heb., 'my master,' 'my teacher'), an honorary title of the Jewish Masters of the Law, which is first found applied after the time of Herod, subsequently to the disputes between the two schools of Shammai (q.v.) and Hillel (q.v.). It was in common use at the time of Christ, who is addressed as such by his disciples and the common people. Other forms of the same title are *Rab* ('master'), *Rabbān* ('our master'), and the Hellenistic *Rabboni* ('my master'). The title Rabbān was first given to the grandson of Hillel, Gamaliel (q.v.), as prince-president of the sanhedrim, and was only borne by seven other exalted chiefs of schools. At present nothing but the degree of *Morenu* ('our teacher'), bestowed upon a candidate who proves his erudition in the written and oral law and all its bearings before a college of rabbis, is wanted to render him eligible for the post of a rabbi, which, however, carries no authority whatsoever with it, save on a very few ritual points. It is a mere ignorant error to hold that the rabbi of our day is a kind of 'priest' in the sense of the Old Testament. He is simply the teacher of the young, delivers sermons, assists at marriages and divorces, and the like, and has to decide on some ritual questions. Up to the times of the removal of Jewish disabilities in Europe (see JEWS, Vol. VI. p. 328) he had on some occasions also to give judgment in civil matters. For the later Jewish, or so-called *Rabbinical*, literature, see JEWS, Vol. VI. p. 331 *et seq.*; for Rabbinical Jews and Rabbanites, see the same article, p. 330.

Rabbit (*Lepus cuniculus*), a well-known rodent in the same genus as the hare, from which it differs in some external features and yet more in its habits. The rabbit is smaller than the hare, with shorter head, ears, and legs; the ears are shorter than the head, and have no black patch at their apex, or at most a very small one; the hind-legs are not so much longer than the fore-legs as they are in the hare; the predominant colour is gray. Moreover, the rabbit brings forth blind and naked young, which it nurtures in the safe retreats afforded by the burrows. These burrows are often of great length, have a crooked course, and generally several openings. Rabbits live socially, and prefer for their warrens places where the soil is loose and dry, and where furze or other brushwood affords additional shelter. They feed on grass, herbs, and tender bark. Their reproduction is very prolific, for breeding may occur four to eight times during the year, the period of gestation lasts only thirty days, three to eight young are born at once, and sexual maturity is reached in about six months. A tame rabbit has been known to bear fifty-eight young in a year, and Pennant calculated that from one mother no less than 1,274,840 descendants might result by the end of four years, assuming that all the members of successive generations survived and reproduced. The young are born—naked, blind, and helpless—within the burrow in a special brood-chamber or nest lined by some of the mother's fur. The mother-rabbit takes much care of her young, nor is the male lacking in affection, though in abnormal conditions he sometimes destroys the brood. For periods at least rabbits are monogamous, and the males exhibit much affection for their mates and hatred of rivals. The normal length of life seems to be about seven or eight years. The gregarious life of a rabbit warren needs no description, but it may be noticed that adjacent burrows sometimes intersect. The senses of rabbits are acute, but their intelligence is not highly developed. They are most active in the gloaming and darkness. Their chief enemies are birds of prey such as hawks and owls, and carnivores such as fox and weasel. By stamping with the hind-legs the older rabbits give signals when danger threatens. It is said that the whiteness of the exposed under sides of the tails is of advantage in indicating the direction of movements, but one would think that it must be also disadvantageous in making the retreating rabbit more conspicuous.

Tame rabbits are varieties of the wild form, modified by the artificial selection usually associated with domestication. Among the more important breeds are the 'silver rabbits' with bluish-gray silvery fur, the 'Russian rabbits' with gray body and brown head, the 'Angora rabbits' with short ears and very long silken fur. Albinos with white hair and red eyes are common. The domestic varieties, especially the last, are much less hardy than those which run wild. Some remarkable modifications have occurred among rabbits in which cross-breeding has been prevented by insulation. Thus there are local varieties in the Falkland Islands and in Jamaica. Most remarkable are the dwarf-rabbits of Porto Santo, one of the Madeiras, which are said to be the descendants of a single litter left there in the beginning of the 15th century. These are so much modified that they do not breed with other rabbits. Hybrids between hare and rabbit are not uncommon in France. In regard to the keeping of tame rabbits, it may be noticed that they eat almost any kind of vegetable food; the coarser blades of cabbages, turnip-leaves, celery-tops, carrot-tops, and other produce of the garden, not suitable for human use, are readily consumed by them, as well as chickweed, sow-thistle, dandelion, and many other weeds. When the rabbit-enclosure contains a plot of grass and clover it affords them an important part of their food. Great care is requisite to keep their boxes dry, neglect of which, and a too exclusive feeding with green and succulent food, cause

diseases, often fatal, particularly to the young. Dry food, such as corn, ought to be frequently given; and aromatic herbs, such as parsley, thyme, and milfoil, not only tend to preserve the health of rabbits, but to improve the flavour of their flesh. It is usual to give no water to tame rabbits; but it is better to supply them regularly with it, and the females need it after producing young. See books by 'Cuniculus' (1889), Edwards (2d ed. 1887), Knight (1889), Rayson (2d ed. 1889), J. Simpson (1893), and J. E. Harting (1898).

It is believed by many that Spain was the original home of rabbits, and that they were, until comparatively recent times, confined to the Mediterranean region. It is certain that in Spain, and still more in the Balearic Isles, they did tremendous havoc in the 1st century B.C.; still it seems that bones of rabbits have been found in Quaternary deposits north of the Alps. Rabbits spread very rapidly. In some parts of Scotland they were hardly known in the 18th century, though elsewhere they abounded. Their introduction into Ireland is also recent. They are not able to stand great cold, and are therefore absent from Scandinavia and North Russia. The most signal instance of their rapid distribution is to be found in their present abundance in Australia and New Zealand, into the latter of which countries seven rabbits were first turned out near Invercargill, apparently about 1860. As to Australia, the agent-general for New South Wales writes (1891) that 'this department is unable to state the exact date when rabbits were introduced into the colony, but it is certain that they existed about forty years ago.' And according to the *Victorian Year Book* for 1887–88, tame rabbits were kept in Victoria during the early years of the colony (towards the middle of the 19th century); but rabbits were first turned out on an extensive scale by a landed proprietor in the western district. They bred rapidly, and for several years there was a demand for couples for breeding purposes in most districts, nobody guessing what a plague they were to become. In both Australia and New Zealand they have spread and multiplied to an extent which seriously affects the prosperity of farmers and rearers of stock. The climate and soil are suitable and their natural enemies are few. Many endeavours have been made to exterminate them, but without success. Trapping, poisoning, and hunting them down produce only a temporary reduction of numbers. Pasteur proposed to infect them with fowl-cholera, and to some extent this has been tried. It has been lately suggested that only the females should be killed, so that the predominance of males might result in unnatural conditions fatal to continued existence. Most practicable at present is the use of wire netting. Thus, if the pools where the rabbits drink are surrounded with netting, thousands die of thirst in a short time. In New South Wales alone the outlay for rabbit destruction since 1883 has been over £1,000,000; as many as 27,000,000 have been killed in one year, and their skins paid for. California and Idaho have also suffered severely from the rabbit pest.

Besides eating up crops and pasture, rabbits often do great harm by barking young trees, and also by their burrowing. On the other hand, the white flesh of rabbits forms excellent food, the skin and the fur are much used, and, as Gilbert White noticed, rabbits by their nibbling make 'incomparably the finest turf.' The preserving of rabbits in tins is in some places an important industry. Rabbits are not technically game (see GAME-LAWS). The old English name for the rabbit is *cony*, but the cony of Scripture belongs to the genus Hyrax, anatomically a very different animal. See HARE, RODENTS.

RABBIT-SKINS have a regular commercial value in consequence of the hair being well adapted for felting purposes; its chief use is in making the bodies of felt hats and imitations of several of the more valuable furs. There has been a very large market in the United States for the imitation furs prepared from rabbit-skins, to which country British manufacturers have largely exported. Tasmania exports about 30,000 rabbit-skins per month to England. See FELT, FURS, HATS.

Rabelais, FRANÇOIS. According to the statements of those who wrote while his tomb was still standing with his name and age upon it, who had access to the church register of Meudon, and who visited the place of his birth while his memory yet lingered, in order to collect every fact that could be found concerning him, this great humorist was born in the year 1483. His father, proprietor of a vineyard called La Devinière, was an apothecary in the town of Chinon, where his house, which afterwards became a *cabaret*, is still shown. François was the youngest of five sons. Of his elder brothers nothing whatever is known. Bishop Huet, annotator of Rabelais, found an old woman of the name in a village near Chinon, and gathered a local tradition that the last male representative of the family, an apothecary, had died at Chinon in great poverty.

Copyright 1891 in U.S. by J. B. Lippincott Company.

At the age of nine the boy was sent to the convent of Seuilly, near his father's estate. 'There are some mothers,' he wrote years afterwards, 'who cannot bear to keep their children about the house more than nine, or, still oftener, seven years. By only putting a shirt over their frocks and cutting off a little hair from the crown of their heads, and saying certain magical words, they transpose them into birds—i.e. put them into monasteries and make monks of them.' He was, in fact, made a monk at the age of nine, and remained a monk all the best years of his life. One result was that, when he came out again into the world and began to write, he wrote of the world as he remembered it—of Touraine and the Tourangeaux, the stories and songs of the drinkers, the gossip of the women, the merriment and happiness—the wild, the careless happiness—of the whole.

After some time at Seuilly, the boy was transferred to the convent of La Baumette, near Angers. Here was a school founded by King René of Anjou in the year 1464, for providing an education on more liberal principles than those of the old method. At this school he founded a life-long friendship with the three illustrious Du Bellay brothers. Nothing is known about the range of his scholarship while at La Baumette. We may, however, very well understand, from the continued protection which Jean du Bellay (afterwards Cardinal) extended to him, that as a young man he had shown promise and proved his abilities. At the close of his course he took the step for which, no doubt, he had been long prepared—i.e. he became a novice of the Franciscan order. It has been asked why he took a step for which he was eminently unfitted; why he became a Franciscan, one of the order which professed to despise learning, and why he exchanged his own smiling country for the barren heaths of La Vendée. The answer seems obvious: for a poor lad the church offered in some form or other, either as priest, monk, or servant of the cathedral or monastery, a livelihood that was certain although humble. It is manifest that the youngest son of the Chinon apothecary could not expect a certain livelihood, with the power of continuing his studies, in any other occupation. He became a monk and entered the Franciscan convent of Fontenay le Comte simply because this was the convent where some kindly interest found him a place. It must not be supposed that the monas-

teries were at that or at any period willing to accept any lad who wanted to exchange a life of servitude and hard labour for one of ease. Not at all. Interest was required for the admission of a boy: in some houses he must be of good birth, in others he must have shown abilities beyond the common. Rabelais, in fact, had no choice at all but to become a monk if he could get into some convent, and he entered the house of Fontenay le Comte because it was the only convent which offered to receive him.

By this time the Franciscan contempt of learning had undergone some modification. It does not appear that Rabelais was hindered by the brethren in his studies. On the contrary, he had access to a large and well-furnished library, whether outside the House or in it is not known, and he read all the books that he could get; acquiring Greek, Hebrew, and Arabic; studying all the Latin authors within his reach, French of the 13th and 14th centuries, books of medicine, astronomy, botany, mathematics—everything in the omnivorous fashion of his time, when every scholar with a good memory wished to become a *Doctor Universalis*. He had companions in his ardour for learning, especially one Pierre Amy, a brother-monk. Also, the rules of the Franciscans, far less severe than those of the Cistercians, permitted the monks to go outside the house, and in the little town of Fontenay Rabelais found a friend, André Tiraqueau, lieutenant-general of the bailiwick, lawyer, scholar, and writer. Also his early and life-long friend, Geoffroy d'Estissac, Bishop of Maillezais, lived chiefly in his chateau of Ermenaud, close to Fontenay.

Many silly stories have been attributed to Rabelais in these years. They all tend to show him in the light of a monkey, mischievous and impish. We may dismiss them as childish; not, however, that we are to regard him—now a priest—as a person grave and serious, charged with the sense of his sacred responsibilities and his vows: to be a priest in the 16th century is not quite the same thing as to be a clergyman in the 19th. Rabelais was at all times a mirthful man, more given to laughter than to tears, and if he did not play silly tricks upon the brethren he certainly laughed at them. We find him corresponding with the great Budé, as one scholar with another. He is on terms of intimacy with Tiraqueau and his brethren learned in the law. He is on terms of friendship with Bishop D'Estissac. Evidently a monk of repute and distinction, he is far above the heads of his nameless and obscure brethren of the monastery. Then we hear of trouble and persecution. The Franciscan jealousy of the old learning has been transformed into jealousy of the new learning. The brothers take their books away from Rabelais and Amy—perhaps lay the pair by the heels in the convent prison.

When they were released a loathing of the convent fell upon these two scholars. What to do? They opened the Book of Oracles—Virgil—and chanced upon the following line:

> Heu! fuge crudeles terras, fuge littus avarum!

What could this mean but a direct injunction to escape? They obeyed the oracle and fled—they ran away. Rabelais, returning to the world, was past forty years of age. He seems to have sought the protection of his friend Bishop D'Estissac, by whom he was received. Through him, or perhaps through the kind offices of Cardinal Du Bellay, he obtained the pope's permission to pass from the Franciscan to the Benedictine order. But he was in no hurry to enter another cloister. He remained at Ligugé with the bishop for six years. It is said that during this period he took a small country living, but this is doubtful. Most likely he passed the whole time in study. Perhaps he paid visits to Paris and Bourges. He made the acquaintance of Marot, who wrote a sonnet for him. His reading had now ceased to be encyclopædic: its special aims may be inferred from the fact that on the 17th day of September 1530 he entered the university of Montpellier as a student. That he was already known as a scholar is also proved by the fact that two months afterwards he was excused the undergraduate course of three years, was admitted to the Bachelor's degree, and allowed to lecture on Hippocrates and Galen. He dissected publicly before the students, and left the university in the year 1532, returning in 1537 to take the Doctor's degree.

In 1532 Rabelais went to Lyons to get his first book, *Hippocratis et Galeni libri aliquot*, published. He remained there as physician to the hospital. At this time Lyons was as great an intellectual centre as Edinburgh about the beginning of the 19th century. Here the great printer Gryphe had his workshop, and issued no fewer than three hundred books, including the Latin Bible of 1550, remarkable for its correctness and for the beauty of its type, and the commentaries of the unfortunate scholar Dolet, in two folios of 1800 columns each, and only eight errata for the whole work. Round this printer was gathered a company of scholars and poets called the *Société Angélique*, a company of broad thought and advanced opinions. As regards religious opinions, it must be remembered that to the scholars of that period the Christian religion meant little more than the Roman ritual and the Roman discipline. They had no idea of Christianity apart from the superstitions they derided. It is not fair to call them atheists: they had adopted the vague but hopeful agnosticism of Cicero: they would not, being scholars, wholly die: they would, after death, be allowed still to watch the advance of learning. Men, for example, who were physicists, like Rabelais, would worship the Creator of the vast and wonderful cosmos. Dolet represents the scholars of Lyons, Desperiers the poets, Rabelais the men of science. All three despised and hated the Church of Rome. Two of them felt the heavy hand of the church in life, the third after death. Dolet was strangled and burned at the stake; Desperiers, starving and despairing, fell upon his sword; Rabelais, dying peacefully, has been assailed ever since as a buffoon and a reveller in foulness and filth.

It was at Lyons that Rabelais began the famous book, or series of books, by which he will for ever be remembered. In the year 1532 he brought out *The Great and Inestimable Chronicles of the Grand and Enormous Giant Gargantua*. Every Tourangeau knew this good giant. Rabelais had heard about him while a child. It was he who set up the dolmen at Poitiers and the *pierre couverte* of Saumur. When he scraped the mud from his shoes he made hills, which may still be seen. He drank at a ford and swallowed six bullocks, a loaded cart, and the driver. Once he swallowed a ship laden with gunpowder. In fact, Rabelais, who never invented anything, but embellished and adorned everything, did not invent Gargantua. In the sequel or second book, *Pantagruel*, the author departed from his first plan: he no longer wrote pure burlesque: serious ideas are set forth side by side with overwhelming nonsense, and the reader steps from unbridled fancy into regions of sense and wisdom. In order to make the first book correspond with the second, Rabelais wrote it all over again, with the result that it is fuller of sense and wisdom than the second. Both books had a prodigious success. They were published under the anagram of Alcofribas Nasier.

At the same time he began his almanac, which

he continued for eighteen years. These are all lost except a few fragments.

In 1534 he accompanied his old friend and patron, Cardinal Du Bellay, to Rome. He promised himself great things on this expedition. He would visit the Italian scholars; he would find new plants; he would dig and discover great things; he would study the topography of Rome. In the end he returned with Marliani's book on Rome, which he translated and published with notes of his own.

In 1535 new editions appeared of the *Gargantua* and *Pantagruel*. In 1536 Rabelais again went to Rome. Some of his letters from Italy to his friend Bishop d'Estissac have been preserved. He obtained absolution from the pope for having forgotten to go into a Benedictine house, for neglecting his Hours, and for practising medicine. He also received permission to go into any Benedictine house which would receive him—time being of course taken to find one. He was enabled to hold ecclesiastical offices, to practise medicine without fees, without the knife, and without fire. He now had nothing to fear from his old enemies of Fontenay le Comte. He amused himself in Italy with collecting curious plants—to Rabelais France first, and England next, owes the melon, artichoke, and carnation: he sent seeds to the bishop and bought curiosities for him.

In 1537 he is found in Paris at the great literary banquet held in honour of Dolet's escape from a charge of murder rising out of accidental homicide. From 1537 to 1539 he resided and taught at Montpellier. In the latter year he went to Lyons, where he stayed a short time only, removing to Paris in 1540. Once more he made things right with the church, obtaining absolution for not having found a Benedictine house, and permission to enter the Collegiate Chapter of St Maur des Fossés instead of a convent, and to hold any benefices which might be conferred upon him. In 1543 he was at Symphorien near Lyons—where he witnessed the death of Guillaume du Bellay—at Chinon, Ligugé, and Angers.

During this time he was writing his third book. It was a dangerous time for heretics. A whisper of heresy at the outset might not only ruin the book, but also bring the author to the stake. He caused the first two books to be read to the king, who was so pleased with them that he gave permission for a new edition, and granted a license for the publication of the third. Rabelais did not avail himself of the permission for a new edition. Already many impieties had been pointed out which he declared were due to the printers, interpolations, misreadings, and so forth. Best not to bring out a new edition. But he printed his third book. This was in 1546.

In 1547 the old king died, and a reaction against liberty of thought immediately began. They attacked Rabelais. Not content with finding impieties in the first three books, they printed a thing which they called his fourth book. Rabelais fled: he went to Metz, where he practised medicine. Cardinal Du Bellay, himself suspected of liberal tendencies, withdrew to Rome, whither he called Rabelais. On the birth of King Henry's eldest son great rejoicings were held in Rome. Rabelais wrote an account of these, and sent the little book to the Cardinal De Lorraine, a stroke of policy which enabled him to return, and gave him the living of Meudon.

From both sides, Catholic and Protestant, cries came that his book should be suppressed and the author burned. Nothing, however, was done. But Rabelais did not dare to proceed further with the fourth book than the eleventh chapter. There it broke short off. This was in 1549. The author, now growing old, lived quietly at his living, preached, catechised the children, and led an exemplary life. Early in 1553, a fortnight before the parliament allowed the sale of the book, he resigned his living and went to Paris. Here, two months afterwards, he died. It was in the Rue des Jardins, parish of St Paul. They buried him at the foot of a tree, on which his name was carved. The tree was cut down a hundred years afterwards. Ten years after his death appeared the fifth and last book, which had been left in MS., unfinished and without the author's corrections.

These are the facts which have been gleaned concerning the life of this great humorist. The riotous license of his mirth, which is restrained neither by decency nor by reverence, has made him as many enemies as his wisdom has made him friends. This fault, which Rabelais shares with many writers of his age—our own dramatists were quite as bad—has been made the most of by the former, his enemies. We may grant the blot: yet it is not inherent in the book; it is not woven in the web: and when it is removed there remains the most astonishing treasury of wit, wisdom, common-sense, and satire that the world has ever seen. All, however, assumes the form of allegory: those who have no taste for allegory cannot appreciate Rabelais.

Among the many modern editions of Rabelais may be named those of Lacour and A. de Montaiglon (3 vols. 1868–73), that in the 'Collection Jannet' (7 vols. 1867–74), the Jouast edition (4 vols. 1885), and especially that in the 'Collection Lemerre,' by Ch. Marty-Laveaux (in 6 vols., i. to iv., 1868–81). See Delécluze, *Rabelais* (Paris, 1841); Lacroix, *Rabelais, sa Vie et ses Ouvrages* (Paris, 1859); Fleury, *Rabelais* (2 vols. Paris, 1874); Urquhart and Motteux's English translation (1653–94, suppressed); the present writer's *Rabelais* (Blackwood's Foreign series, 1879), and his *Readings in Rabelais* (1881); Stapfer, *Rabelais* (1889); Heulhard, *Rabelais: ses Voyages en Italie, son Exil à Metz* (1891); René Millet, *Rabelais* ('Grands Écrivains,' 1893).

Racahout, a farinaceous food prepared from certain acorns. See OAK, Vol. VII. p. 561.

Racalmuto, a town of south Sicily, 13 miles by rail NE. of Girgenti. Pop. 13,133.

Racconigi, a town of North Italy, 23 miles by rail S. of Turin, with a royal palace. Pop. 7875.

Raccoon, or RACOON (*Procyon*), a genus of quadrupeds of the Bear family (Arctoidea), with six

Raccoon (*Procyon lotor*).

molar teeth on each jaw; like other Arctoids, it is plantigrade, and has no retractile claws. There

are certainly two, possibly three, but not more than four species of raccoon, which are restricted to the American continent. In North America we meet with the 'coon' (*Procyon lotor*), so called from the habit of soaking its food in water. This animal prefers open woods, and is a good climber, making its home in trees. The raccoons, however, descend to the ground to search for their food, which consists chiefly of aquatic animals, fish, crayfish, and various shellfish; they will also feed upon corn. These animals are among the most strictly nocturnal of mammals; they hibernate during the winter. In South America occurs *P. cancrivorus*, and a well-marked variety which may be a distinct species, and has been named *P. nigripes* on account of its dark-coloured feet. For the Raccoon Dog, see DOG.

Racemic Acid. See TARTARIC ACID.

Rachel, ÉLISA (properly ÉLISA RACHEL FÉLIX), a great tragic actress, was born of poor itinerant Jewish parents at Munf, in the Swiss canton of Aargau, 24th March 1821. At last the family settled at Lyons, and here Rachel and her sister Sarah used to sing for chance gratuities in the streets and cafés. About 1830 the household was transferred to Paris, and here Étienne Choron gave her her first lessons in singing, Saint Aulaire in declamation; but later it was Samson from whom she learned most. Mademoiselle Mars divined her genius, but it was not till Véron and Jules Janin had written glowing criticisms that she took the playgoing world of Paris by storm. She made her first appearance at the Gymnase in the *Vendéenne* in 1837 with but moderate success, but on 12th June 1838 she appeared as Camille in *Les Horaces* at the Théâtre Français. From this time forward, in the great parts supplied by the classic masterpieces of Corneille, Racine, and Voltaire, she shone without a rival; her fame may be said to have culminated in her appearance as Phèdre in Racine's tragedy in 1843. In *Adrienne Lecouvreur*, a piece expressly written for her by MM. Legouvé and Scribe, she had also immense success, though in other more modern parts her popularity was somewhat less. The *furore* excited in Paris in 1848 by her public recitation of the *Marseillaise* will continue to connect her name with the history of the Revolution. In 1849 she made the tour of the French provinces; before or afterwards she also visited London, Belgium—where Charlotte Brontë saw her—Berlin, and St Petersburg, everywhere meeting with enthusiastic applause. Her health now began to fail; in 1855, in the course of a professional visit to America, it altogether gave way, and she returned utterly prostrated. A residence at Cairo failed to restore her to strength; and on the 3d January 1858 she died at Cannet, near Toulon. As an artist, within the limits prescribed by her genius, Rachel has probably never been quite equalled. Of the burning intensity which characterised her rendering of passion in its fiercer concentrations no words can give an adequate image. 'She does not act—she suffers,' one observer well said of her. Her Phèdre—by common consent her masterpiece—was an apocalypse of human agony, not to be forgotten by any one who ever witnessed it. In character Rachel was neither exemplary nor altogether amiable. She gave her first love to a Jew, who used her shamefully, publishing her letters after the rupture; in 1844 she bore a son to Count Walewski, himself a son of Napoleon by a Polish mother. In her professional relations she was notoriously grasping and avaricious, although she could be royal in her munificence. She lavished her love upon her family, and heaped them with the wealth that she had gained. Her immense popularity enabled her to dictate her own terms to managers, and of this power she is said to have availed herself without scruple or generosity. She made over four millions and left one and a half million of francs. Her elder sister Sarah (died 1877) failed as an actress, but lived to make a fortune by the sale of the cosmetic 'eau des fées.'

See J. Janin, *Rachel et la Tragedie* (1858); D'Heylli, *Rachel d'après sa Correspondance* (1882); and the Life by Mrs Arthur Kennard (1885).

Rachis (Gr., 'backbone'), in Botany, the *primary floral axis*, an elongation of the stem or of a branch, from which arise the flower-stalks (peduncles), or to which the flowers are immediately affixed.

Racine, capital of Racine county, Wisconsin, is situated on Lake Michigan, and on both sides of Root River, which is crossed by five swing bridges, and whose mouth here forms an excellent harbour. By rail the city is 62 miles N. of Chicago and 23 S. of Milwaukee; and in summer there are daily steamers to Chicago and the north. Racine contains a handsome post-office and city hall, a hospital, the Taylor Orphan Asylum, and the University of the North-west (Episcopalian, founded in 1852, and formerly called Racine College). A large trade is carried on in lumber, and, besides flax, flour, and woollen mills, boiler-works, and linseed-oil works, there are manufactories of ploughs, pumps, wagons, fanning-mills, hardware, wire-work, cordage, furniture, refrigerators, boots and shoes, rubber clothing, &c. Pop. (1880) 16,031; (1890) 21,014.

Racine, JEAN, the greatest tragic dramatist of France, was born at La Ferté-Milon, in the modern department of Aisne, in December 1639, and was baptised on the 22d of that month. His father was a *procureur* or solicitor by profession, and held, like his father before him, the office of comptroller of salt at La Ferté. His mother died while he was still a child, whereupon his father married again, but soon after died also. The boy was taken care of by his maternal grandfather, and was sent for his education to the college of Beauvais, whence he passed to Port Royal in October 1655, being, indeed, closely connected, both on the father's and mother's side of the family, with the famous abbey. Here he studied hard under the especial care of Claude Lancelot, Nicole, and Le Maître, and at an early age discovered a faculty for verse-making and, still worse, a liking for romance that caused his good teachers no small uneasiness. He was almost nineteen when he left Port Royal to pursue the course of philosophy at the Collége d'Harcourt, and here he appears to some extent to have exchanged the severity of his Jansenist upbringing for the libertinism of the world of his day, as well as to have first felt the attraction of the life of letters. Naturally he became estranged from his Port Royal friends, who saw spiritual ruin in his worldliness and his intimacy with the abhorred actors and actresses. Meantime he had written an ode, *La Nymphe de la Seine*, on the marriage of Louis XIV., finished one piece and begun another for the theatre, and made the acquaintance of La Fontaine, Chapelain, and other men of letters. About this time he lived a while under the care of his cousin, N. Vitart, fifteen years his senior, and gave him some kind of assistance in his work as financial secretary to the Duc de Luynes. Many letters of this period to Vitart, the Abbé Le Vasseur, and La Fontaine are extant, and show how the lessons of Port Royal were fading into

forgetfulness, as his true vocation opened itself up before his eyes. The great dispersion of the *solitaires* of Port Royal took place in 1661, and, from Racine's contemporary letters to the Abbé Le Vasseur, it troubled him but lightly. In November 1661 he went to Uzès in Languedoc, hoping, but in vain, to get a benefice from his maternal uncle, the vicar-general of the diocese, and here he divided his time between St Thomas, Virgil, and Ariosto. Again in Paris before the beginning of 1664, he obtained in August of that year a pension from the king of six hundred francs for a congratulatory ode. But indeed he received almost to the end of his life handsome rewards in money—'gratifications'—from the court. An ode of gratitude to the king for one of these, *La Renommée aux Muses*, gained him the life-long friendship of Boileau, and from about this time began the famous but much over-estimated friendship of 'the four'—Boileau, La Fontaine, Molière, and Racine. Unfortunately from about this point there is a break in his correspondence, so that we lack satisfactory evidence about the most doubtful and, at the same time, interesting points in his career—his singular spite against Molière, his bitter attack upon Port Royal, and his final conversion and retirement from dramatic work. His earliest play, *La Thébaïde ou Les Frères Ennemis*, was acted by Molière's company at the Palais Royal theatre in June 1664; his second, *Alexandre le Grand*, in December 1665. After the sixth performance the latter was without explanation represented by the rival actors at the Hôtel de Bourgogne—a fact which of course involved a complete breach of friendship between Molière and himself. This famous quarrel is difficult beyond most to clear up, but there is at least light enough to see that the wrong did not rest with Molière. Racine showed himself as hostile to Corneille, most probably only because the older dramatist judged the younger's work somewhat severely. But he soon plunged into a yet more discreditable quarrel. Stung by one of Nicole's *Lettres Visionnaires* (January 1666) condemning the romancer or the dramatic poet as an 'empoisonneur public' in accordance with the ethics of Port Royal, he published a clever and stinging letter to the author, in which he heaped disgrace on his own head by indecent personalities upon Nicole and even his dead teacher Le Maître. Boileau's advice alone saved him from further shaming himself with a second. 'This letter,' said Boileau, 'may do credit to your intellect, but certainly none at all to your heart.' Later in life Racine himself said he would give his heart's blood to wipe out the most disgraceful blot upon his life. His repentance made noble atonement for the wrong—as for the literary quality of the letters, for brilliant wit and delicate irony they were not unworthy of the hand of Pascal.

During the next thirteen years Racine produced his greatest work, seeking relaxation from labour in at least one liaison with an actress. His plays followed in this order: *Andromaque* (1667), with its charming character Hermione; *Les Plaideurs* (1668), a delightful little comedy of satire against lawyers, which Molière was the first to appreciate; *Britannicus* (1669), which Voltaire styled 'la pièce des connaisseurs;' *Bérénice* (1670), written unconsciously in competition with Corneille, the same theme having been given to both poets by Henrietta of Orleans; *Bajazet* (1672), admirable, but anything rather than oriental; *Mithridate* (1673), produced almost at the moment of his admission to the French Academy; *Iphigénie* (1675), a masterpiece of pathos; and *Phèdre* (1677), a marvellous representation of human agony, which afforded a subject adequate even to the powers of Rachel. With the last ended abruptly his thirteen years of unbroken playwriting. A few days after its production the Troupe du Roi introduced an opposition *Phèdre*, by Pradon, which, though worthless by comparison, was eagerly supported by a powerful party, including the famous Duchess of Bouillon. Whether from disgust and mortification, or from the conversion attributed to him just at this period, Racine turned at once from dramatic work, made his peace with Port Royal, married on June 1, 1677, and settled down to twenty years of domestic happiness. His wife brought him money, if she bore him five daughters and two sons; and he himself had found ample profit in the drama, besides enjoying an annual *gratification* that grew gradually from 800 to 2000 livres, not to speak of the office of treasurer of France at Moulins, at least one benefice, and from 1677, jointly with Boileau, the office of historiographer-royal of France, with a salary of 4000 livres a year. The last involved the duty of accompanying the king on several of his expeditions, but in the case of both poets bore little historical fruit beyond a crop of good intentions and a few fragments. In January 1685 Racine emerged from his retirement to pronounce the discourse at the reception to the Academy of Thomas Corneille, and at last did himself honour by his admirable eulogium upon his greater brother.

In 1689 he wrote *Esther*, in answer to a request from Madame de Maintenon for a play suitable for her girls at Saint-Cyr. She had tried *Andromaque*, but found that the girls acted it 'a great deal too well.' Its success was great, but entirely warranted by the exquisite art of the poem. *Athalie* followed in 1691 with much less success, though it perhaps deserved even a greater. Four *cantiques spirituelles*, and an admirably written *Histoire abrégée de Port Royal*, make up the whole remainder of Racine's literary work. In his later years he lost the favour of the king—how is not by any means clearly understood. He is said to have prepared a memoir on the miseries of the people, and the king, finding Madame de Maintenon reading this, expressed his displeasure in some harsh words that broke the sensitive heart of the courtier-poet. On 4th March 1698 he wrote a long letter to Madame de Maintenon, to clear himself from the crime of Jansenism, but he never recovered the king's favour, and his acute mortification appears to have hastened his death. He said to Boileau, with the sweet graciousness of his nature, as he embraced him for the last time, 'Je regarde comme un bonheur pour moi de mourir avant vous.' He died 21st April 1699, and was buried by his own desire in Port Royal.

In France it remains an article of patriotism to claim Racine as the greatest of all masters of tragic pathos, yet this estimate does not very greatly exceed the truth. He took the conventional French tragedy from the stronger hands of Corneille, and added to it all the grace of which it was capable, perfecting exquisitely its versification, and harmoniously subordinating the whole action to the central idea of the one dominant passion. But he was a far greater poet even than a dramatist, and the tender sweetness and beauty of his rhythm, the finished perfection and flexibility of his cadence, and the indefinable yet ever present stamp of distinction that informs his style, combine to add a charm of its kind beyond almost anything else in the whole poetry of France. It may be that the highest poetry of all is beyond his reach, and that his verses are only for a sensitive ear, but such they haunt with a peculiar charm beyond the art of a Lamartine or a Hugo. Within its limits his poetry attains the perfection of the classic in the highest as well as severest sense of the term; it sums up in its

content all that was noble in the royalism of the 18th century, and in the spiritual aspirations out of which grew a Mère Angelique and a Pascal; and it attains the Olympian height of distinct originality as well in the balanced proportion and harmony of all its elements as in the grandeur and sublimity of which it is capable of rising in a *Phèdre*, an *Esther*, and an *Athalie*. These high creations transcend and crown with the glory of completion his habitual tenderness and beauty, but into this empyrean also the poet soars no less naturally on the same strong and steady wing. Voltaire, when asked to write a commentary on Racine, answered, and with truth: 'Il n'y a qu' à mettre au bas de toutes les pages—beau, pathétique, harmonieux, admirable, sublime.'

The first collected edition appeared 1675-76; the last within his life-time in 1697. Of more important editions may be named the splendid folio of 1805, those of La Harpe (with commentary, 1807), Geoffroy (1808), Aimé Martin (1820), A. France (5 vols. 1874), and especially the splendid edition by Paul Mesnard in 'Les Grands Écrivains de la France' (8 vols. 1865-73). The first volume of the last contains a Life; the eighth, a Lexique by Marty-Laveaux. Of English translations are the *Distressed Mother*, by Ambrose Philips (1712), the *Phœdra and Hippolytus*, by Edmund Smith, brought out at the Haymarket in 1707; and a complete metrical version by R. B. Boswell (vol. i. 1889; vol. ii. 1891). See vol. vi. of Sainte-Beuve's *Port Royal*, and vol. i. of *Portraits Littéraires;* also Henry M. Trollope's *Corneille and Racine*, in the series of 'Foreign Classics.'

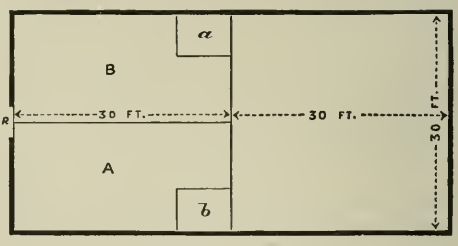
Racing. See ATHLETICS, HORSERACING, ROWING, YACHT.

Rack, an instrument of Torture (q.v.) used for extracting confessions from actual or suspected criminals, consisted of an oblong frame of wood, with a windlass arrangement at each end, to which the sufferer was bound by cords attached to his arms and legs. The unfortunate being was then stretched or pulled till he made confession, or till his limbs were dislocated. The rack was known to the Romans in Cicero's time, and in the 1st and 2d centuries A.D. was applied to the early Christians. According to Coke, it was introduced into England by the Duke of Exeter, Constable of the Tower in 1447, whence it came to be called the 'Duke of Exeter's daughter.' Its use first became common in the time of Henry VIII., but could only take place by warrant of council, or under the sign-manual. Under Elizabeth it was in almost constant use. In 1628, on the murder by Felton of the Duke of Buckingham, it being proposed by Charles I. to put the assassin to the rack, in order that he might discover his accomplices, the judges resisted the proceeding as contrary to the law of England. In various countries of Europe the rack has been much used both by the civil authorities in cases of traitors and conspirators, and by the Inquisition to extort a recantation of heresy. It is no longer in use in any part of the civilised world.

Rackarock. See BLASTING.

Rackets (or RACQUETS; M.E. *raket;* Span. *raqueta*, 'racket,' 'battle-dore;' Arab. *rahat*, 'palm of the hand'). No reference is made to the game of rackets before the early part of the 19th century, and the game as then played differed materially from that of the present day. From Dickens's account in *Pickwick* we should gather that the racket-court in which the insolvent debtors disported themselves in the Fleet boasted of more than one wall, but the usual game was played against a single wall, the ball having to rebound into a court marked out with paint. The erection of the courts at Prince's Club in 1853 showed that the four-wall game was coming into favour, and since covered courts have been adopted by the universities and public schools the old game has become practically obsolete. When the site of Prince's Club was invaded by the builder in 1886 the headquarters of rackets were transferred to the Queen's Club, Kensington, where championship matches have been instituted, and where the university and public school contests now take place.

The modern court is about 60 feet long by 30 feet broad and 40 feet high. It is enclosed by four walls, and covered by a roof with a double row of skylights. The walls and floor are coated with cement, usually coloured black, and marked out by white lines as shown in the plan. A line 8 feet from the ground painted across the front wall is called the 'service line.' Below this at 2 feet is the 'play line,' which is made of wood, so as to enable the players to judge by the sound whether a ball is 'up' or not. The racket has a small head with tightly strung gut and a long handle. The average weight is 9 oz. The ball is very hard, and about 1¼ inch in diameter. The server strikes the ball alternately from the two serving boxes *a* and *b* in such a manner that it flies direct from his racket to



Plan of Racket Court.

some part of the front wall above the service line, and rebounds into that quarter of the court opposite to him—viz. from *a* into A, from *b* into B. If the ball hits the wall below the play line, or goes 'out of court,' the server's 'hand is out,' and his opponent has the privilege of serving. If it strikes the wall between the play line and the service line, or falls on some part of the floor other than that indicated, it is a 'fault,' and the servee may refuse to take it. Two faults put the hand out. The servee must return the service above the play line. The game consists of fifteen aces, and the server scores an ace when the striker out fails to return his service or any ball in the subsequent 'bully.' See *Tennis, Lawn Tennis, Rackets, and Fives*, in the 'Badminton' series, by J. M. Heathcote and others (1890).

Racoczy. See RAKOCZY.

Racoon. See RACCOON.

Racoonda, the fur of the Coypu (q.v.).

Racow, a village in the south of the Polish government of Radom, was in the 16th century a centre of the Socinians, who printed here their Catechism (q.v.). Pop. 2109.

Radcliffe, a town of south-east Lancashire, on the Irwell, 2½ miles SSW. of Bury and 7 NNW. of Manchester. It has an ancient parish church (restored 1873), a ruined tower, a market-hall (1852), a co-operative hall (1878), cotton and calico works, bleachfields, and coal-mining in the neighbourhood. Pop. (1851) 5002; (1881) 16,267; (1891) 20,020.

Radcliffe, ANN, novelist, was born in London, 9th July 1764, of respectable tradespeople with good connections. Her maiden name was Ward, but in her twenty-third year, at Bath, she married William Radcliffe, a graduate of Oxford and sometime student of law, who became proprietor and editor of the weekly *English Chronicle*. She took

to writing to pass the time when alone, and as early as 1789 published *The Castles of Athlin and Dunbayne*, which was followed by *A Sicilian Romance* (1790), *The Romance of the Forest* (1791), *The Mysteries of Udolpho* (1794), and *The Italian* (1797). For the last she received £800; for its predecessor, £500. From this time she published no more novels—'like an actress in full possession of her applauded powers,' says Scott, 'she chose to retreat from the stage in the full blaze of her fame.' She travelled with her husband abroad and all over England and Wales, and the jottings in her journal show how keen an eye she had for natural scenery, and how carefully she got up her castles and ruined abbeys. She was a modest and amiable woman, who did not publish herself nor sink the gentlewoman in the writer. So little was she known to the public that in her own lifetime there was widely current an absurd story that her mind had given way under the horrors evoked by her imagination. She suffered for twelve years from asthma, and died 7th February 1823. A sixth romance, *Gaston de Blondeville*, with a metrical tale, 'St Alban's Abbey,' and other poems, and a short life, was published in 1826.

As a novelist Mrs Radcliffe stands in time between Horace Walpole and Clara Reeve on the one hand and Sir Walter Scott on the other. She was mistress of every art of awakening the curiosity and enchaining the attention of a reader, and she displays great artistic power in the atmosphere of majestic gloom and mystery in which she enwraps her figures. She knew well how to make use of forest solitudes and every aspect of external nature suggestive of terror, but she ever failed lamentably in the conclusion of her stories by resolving the seemingly supernatural effects of the preceding pages into simple natural causes which the reader resents as inadequate. Further, her figures are mere shadows, without touch of reality, and her pages are unrelieved by ever a gleam of humour or even wit. But she was dear to our grandfathers, dearer still to our grandmothers; Crabb Robinson preferred her stories to *Waverley;* and so sagacious a writer as Dunlop could write, 'life has few better things than sitting at the chimney-corner in a winter evening and reading such absurdities.'

See Sir Walter Scott's *Biographical Notices of Eminent Novelists*, and Julia Kavanagh's *English Women of Letters* (2 vols. 1863).

Radcliffe, John, physician, was born at Wakefield in Yorkshire, in 1650, and studied at Oxford, passing M.A. in 1672, and M.B. in 1675. Beginning practice, he immediately made himself conspicuous by the originality of his ideas, claiming to take nature for his guide, and in less than two years was on the high road to celebrity. In 1682 he became M.D., and in 1684 removed to London, where he soon became the most popular physician of his time. It is said that his conversational powers, ready wit, and pleasantry contributed to this result quite as much as his professional skill. In 1686 the Princess Anne of Denmark made him her physician; and after the Revolution he was sent for by King William. In 1694 he was called upon to attend Queen Mary, when attacked by the smallpox, and did what he could to save her, but in vain. In 1713 he was elected M.P. for Buckingham. He had a country-house at Carshalton, and here he was living in 1714 when Queen Anne was attacked with what proved to be her last illness. Dr Radcliffe was summoned to attend her; but he was ailing, and either would not or could not come. The queen died in August; and the populace were so enraged against Dr Radcliffe that he dared not again show his face in London. He must have been really ill when sent for to the queen; he died of apoplexy at Carshalton on 1st November 1714, and was buried at Oxford in St Mary's Church. He bequeathed the bulk of his large property to public uses, leaving £40,000 for the erection of the Radcliffe Library, whose books were mostly taken in 1861 to the University Museum; while the building now serves as a reading-room for the Bodleian (q.v.). Other bequests were made to University College and St Bartholomew's Hospital, London.

Radclyffe. See Derwentwater.

Raddle. See Reddle.

Radetzky, Johann Joseph, Count, an Austrian field-marshal, was born at Tzrebnitz Castle near Tabor in Bohemia, on 2d November 1766. Entering the Austrian army in 1784, he made his first campaign against the Turks in 1788-89, and afterwards fought in nearly all the wars waged between the Austrians and the French, especially distinguishing himself at the battles of the Trebbia, Novi, Hohenlinden, Wagram, and as Schwarzenberg's chief of the staff at Leipzig. In 1831 he was sent to take command of the Austrian forces in the Lombardo-Venetian territories, and five years later was made field-marshal. When the people of Lombardy rose in revolt against Austrian rule in 1848 Radetzky, an old man of eighty-two, after five days' street fighting, was driven out of Milan. Concentrating in Verona and Mantua, he proved the chief mainstay of the House of Hapsburg during the 'year of revolutions.' Nevertheless he was defeated by the king of Sardinia at Goito on the Mincio, when marching to the relief of Peschiera, in May. Peschiera capitulated immediately afterwards. Having received heavy reinforcements, Radetzky towards the end of July broke out of Verona, routed the Sardinian-Piedmontese army at Custozza, and on 6th August re-entered Milan. Three days later an armistice was concluded, the king of Sardinia abandoning all places east of the Ticino. On the resumption of hostilities in March 1849 the Austrian general in a campaign of less than a fortnight crossed the Ticino and almost destroyed the Piedmontese army at Novara (23d March). In the following August he compelled Venice to surrender, it having been in revolt since 1848. After this Radetzky was appointed governor of the Lombardo-Venetian territories, and ruled them with an iron hand until the beginning of 1857. He died at Milan on 5th January 1858, and was buried at Metzdorf near Vienna.

See his own *Denkwürdigkeiten* (1887) and his *Briefe an Seine Tochter* (1892), and lives or books about him by Strack (1849), Schneidawind (1851), Schönhals (1858), Trubetzkoi (1860), Kunz (1890), K. von Duncker (1891), Smolle, Krones, Grasser, Bancalari (1892), and Hübner, *Une Année de ma Vie* (1891).

Radhanpur, chief town of a protected state in Bombay Presidency, India, 150 miles NW. of Baroda. It is surrounded with walls and encloses a fortified castle, the residence of the native prince. Pop. 14,722. The state of Radhanpur has an area of 1150 sq. m. and a pop. of 98,129.

Radiant Energy. See Energy.

Radiant Matter. See Vacuum Tubes.

Radiata, one of the four *embranchemens* into which Cuvier (1812) divided the animal kingdom, the other three being Articulata, Mollusca, and Vertebrata. In the division Radiata Cuvier recognised five classes—viz. (1) the Echinodermata, (2) the Entozoa (or Intestinal Worms), (3) the Acalephæ (or Jelly-fish), (4) the Polypi (Hydroids and Polyzoa), and (5) the Infusoria (Rotifers and Protozoa). It is hardly necessary to say that this exceedingly heterogeneous assemblage, or 'radiate mob,' as Huxley termed it, is now broken up into numerous distinct classes.

Radiation. See Heat.

Radical, in Chemistry, is a term applied to a group consisting of two or more elementary atoms which is capable of entering into a series of different compounds without itself undergoing change or decomposition. In this respect a radical resembles an atom of an elementary substance. Radicals are, in a sense, incapable of a separate existence, and must be in combination with other radicals or elements. Two similar radicals can, however, combine with each other, and in such cases the compound produced has been looked upon as the radical in the free state.

The radical *methyl*, CH_3, consisting of one atom of carbon and three atoms of hydrogen, is known in combination with chlorine, iodine, oxygen, and sulphur in the respective compounds, methyl chloride, CH_3Cl, methyl iodide, CH_3I, methyl oxide, $(CH_3)_2O$, and methyl sulphide, $(CH_3)_2S$. Two methyl groups occur in combination with each other in the substance ethan or dimethyl, $(CH_3)_2$ or C_2H_6. A very large number of other compounds contain the radical methyl.

The sulphates, the nitrates, and the acetates contain the respective radicals SO_4, NO_3, and $C_2H_3O_2$. These are frequently called the *salt-radicals* of the respective series of salts. In double decompositions the salt-radical occurring in combination with one metal is transferred, without decomposition, to another metal. For instance, the equation

$$MgSo_4 + Ba(NO_3)_2 = BaSO_4 + Mg(NO_3)_2$$

represents the mutual exchange of salt-radicals by the metals magnesium and barium.

In chemical notation short symbols are frequently employed to represent complicated radicals. Thus, the complex salt-radical of the tartrates, $C_4H_4O_6$, is shortly represented by the symbol $\overline{T}$. Tartaric acid is then represented by $H_2\overline{T}$, potassium tartrate by K_2T, potassium hydrogen tartrate (cream of tartar) by KHT, &c.

Radical, in English politics, is often used to denote the advanced wing of the great Liberal party. The name seems to have been first used in the reign of George III. in the phrase 'radical reform' (*Anti-Jacobin*, 1797 and 1798), though one instance at least occurs much earlier in the *Remains* of Archbishop Leighton, written in the reign of Charles II. (see ROOT AND BRANCH MEN). But the modern radicals are descendants of the French Revolutionists of 1789. The principal objects of the men so designated have been chiefly concerned with parliamentary reform, the extension of the franchise, the enlargement of the public privileges of the people, and with endeavouring to weaken and curtail the exclusive privileges and prerogatives of the oligarchical ruling classes. In a word, the radicals of England have been the pioneers of the democratic movement, and have sought to achieve their ideals almost exclusively through the agency of parliamentary government. The word is meant to indicate the thoroughness of the reforms advocated, being derived from the Lat. *radix*, 'a root.' Inseparably associated with the great reform movements of the 19th century, the radicals began to be generally so called about 1816; and the name figured prominently in the movements in which Orator Hunt (q.v.), Thistlewood, Watson, and others played the chief parts. A clever poem setting forth the aims of these men, entitled *The White Hat* (1819)—i.e. the hat of Hunt, nicknamed King Harry the Ninth—and written by E. L. Swifte, will be found in *Notes and Queries*, series 3, vol. x. p. 436. See also W. Harris, *History of the Radical Party in Parliament* (1885); and S. Bamford, *Life of a Radical* (1842).

Radiolaria, a class of marine Rhizopod Protozoa. Thread-like processes of living matter radiate outwards on all sides; a membranous capsule with fine pores, or with one or more apertures, separates an internal nucleated region of the cell from an outer part supported by a gelatinous framework; there is a hard skeleton of silica or of a 'horny' material called acanthin. They multiply by dividing or by forming spores within the central capsule. Most of the Radiolarians are minute, under $\frac{1}{25}$ of an inch, but a few which form colonies may measure an inch or even 4 inches in length. Most of them include 'yellow cells' or algæ, with which they live in a partnership known as Symbiosis (q.v.). Radiolarians occur in all seas, in every latitude, and at all depths, though many kinds predominate on the surface, where they are wafted about by currents. The siliceous skeletons form most of the ooze which has been dredged from depths of 2000 to 3000 fathoms. Fossil forms are abundant in certain deposits—'Barbadoes earth,' 'Tripoli powder,' and various marls, &c. See Haeckel in the *Challenger* Reports (1887).

Radiography. See RÖNTGEN.

Radiometer, an instrument consisting of four horizontal arms of very fine glass, carefully poised so as to revolve easily on a point; the tips of the arms having pith discs blackened on one side. The whole is contained in a glass vessel almost but not quite exhausted of air. When exposed to light or heat the arms move round, more or less swiftly according to the strength of the rays. The blackened sides of the vanes are warmer: the molecules of air striking those sides are more heated by the vanes: they rebound after impact with greater velocity: the vanes are driven back by a greater recoil on the blackened sides. The radiometer was invented in 1873–76 by Crookes (q.v.).

Radiophone, an instrument, essentially similar in principle to the Photophone (q.v.), for producing sound by means of heat rays.

Radish (*Raphanus*), a genus of plants, of the natural order Cruciferæ, having a spongy Silique (q.v.). The flowers are yellow, red, or purple. The Common Radish (*R. sativus*) has thick, round, tapering, and pointed pods, little longer than their

Long-rooted and Turnip-rooted Radishes.

stalks, very slightly contracted between the seeds, and not falling to pieces. It is not known in any country in a wild state, but has been cultivated from time immemorial in China, Japan, India, and in Europe. But some varieties of the Wild Radish found growing on the Mediterranean coasts resemble

so closely the Garden Radish as to suggest the possibility that the latter may be but a cultivated race of it. Radish is a well-known salad root, much appreciated for its succulent roots with their warm pungent taste. In this way the young and tender leaves were also formerly used. The varieties of radish in cultivation are extremely numerous, but they are generally classed under the two heads of *Long-rooted* and *Turnip-rooted* Radishes, the roots of the former resembling the carrot in shape, and the latter the turnip. The varieties differ very much, not only in form of root, but in colour and size, a red colour generally prevailing. Some of the darker-coloured turnip-rooted radishes, such as the black Spanish, grow to a large size under good cultivation, and are grown in gardens chiefly for their usefulness in winter when the ordinary varieties cannot be grown. Radishes are sown at different seasons, and are generally used when young and small. The root of the radish possesses demulcent, stimulant, and diuretic properties, and is sometimes used in cases of atony, or of excessive secretion of mucus by the organs of digestion or the urinary organs. Radish-juice, mixed with sugar-candy, is a popular and useful German remedy for hoarseness and cough. Distinct from both the varieties above named is the Oil Radish, which has a slender—scarcely fleshy—root, a short much-branched stem, and many-seeded pods. It is cultivated in China for the oil of its seeds. Another species of radish (*R. caudatus*), a native of Japan, is there cultivated as an esculent. To this genus belongs the Jointed Charlock of the cornfields (*R. raphanistrum*), which has found its way from Europe to North America, and is a troublesome weed there also. The seeds, however, may be advantageously crushed for oil. The Sea Radish (*R. maritimus*) is a rarer British species, the roots of which are of fine quality and great pungency.

Radius. See CIRCLE.

Radley, a Berkshire village, near the right bank of the Thames, 5 miles S. of Oxford. The Bowyers' seat here was in 1847 converted by Professor W. Sewell into a High Church public school—St Peter's College—for 130 boarders. It has a fine chapel.

Radnorshire, a border county of South Wales, bounded by the counties of Montgomery, Salop, Hereford, Brecon, and Cardigan. Measuring 36 miles by 30, and 432 sq. m. in area, it is the tenth in size and twelfth in population of all the twelve Welsh counties. The beautiful Wye traces all the south-western and southern boundary, the Teme the north-eastern; and the surface generally is hilly or mountainous, in the Forest of Radnor attaining a maximum altitude of 2163 feet. Of half-a-dozen mineral springs, those of Llandrindod are in most repute. The rocks are mainly Lower Silurian, and the soils poor, less than half of the total area being in tillage, whilst woods and plantations cover nearly 8000 acres. The rearing of stock is the principal industry. Radnorshire returns one member; and till 1885 another was returned by the Radnor district of parliamentary boroughs—Cefnllys, Knighton, Knucklas, New Radnor, Presteigne, and Rhayader. Pop. (1801) 19,135; (1841) 25,458; (1881) 23,528; (1891) 21,791. See Williams' *History of Radnorshire* (Tenby, 1858).

Radom, an old but uninteresting town of Poland, on a sub-tributary of the Vistula, 60 miles S. of Warsaw. It is the seat of an active trade; dyeing is the most important industry. Pop. 12,402.—The *government* has an area of 4768 sq. m. and a pop. (1893) of 782,274.

Radowitz, JOSEPH VON, Prussian statesman, born February 6, 1797, at Blankenburg, was the son of a nobleman of Hungarian descent, and in 1813 entered the Westphalian army as an officer. After the peace in 1815 he taught in the military school of Cassel; but in 1823 he entered the Prussian service, and in 1830 became chief of the general staff of artillery. By his marriage he became connected with the Prussian aristocracy, and soon became the leader of the anti-revolutionary party. In 1836 Radowitz was sent as Prussian military commissioner to the German Diet at Frankfort, and held diplomatic posts at Carlsruhe, Darmstadt, and Nassau. He was the confidant and adviser of King Frederick-William IV. in his endeavours to bring about a reform of the German Diet. After the revolution of 1848 the endeavours of Prussia to give a constitution to Germany, by means of the alliance of the three kings, was principally his work. He wrote several works, mainly political, and died 25th December 1853. See Lives by Frensdorff (1850) and Fischer (1874); and Hayward's *Biog. and Crit. Essays* (1st series, 1858).

Rae, JOHN, Arctic traveller, was born in Orkney in 1813, studied medicine at Edinburgh, and went to Hudson Bay as doctor of the Company's ships. In 1845 he undertook an exploring expedition, and in 1846–47 a more extensive one, wintering in Repulse Bay. He was second under Richardson in 1848 on a Franklin search voyage. In 1853–54 he commanded an expedition that proved King William's Land to be an island. In his various journeys nearly 1800 miles were travelled over for the first time. In 1860 he surveyed a telegraph line to America by the Faroes and Iceland, and visited Greenland; and in 1864 he made a telegraph survey from Winnipeg across the Rocky Mountains. He published reports of his expeditions, and many geographical papers. Dr Rae, who was LL.D., F.R.S., &c., died 24th July 1893.

Raeburn, SIR HENRY, R.A., portrait-painter, was born 4th March 1756, at Stockbridge, then a village near Edinburgh, where his father was a manufacturer and mill-owner. His parents died when he was about six years old; and he was educated in George Heriot's Hospital, and apprenticed to James Gilliland, a goldsmith and jeweller in the Parliament Close. While in this employment his turn for art attracted the attention of David Deuchar, the etcher and seal-engraver, who gave him some instruction; and he afterwards studied under David Martin, producing at first water-colour miniatures with such success that he was soon able to devote himself exclusively to portraiture in oils. A careful miniature of Deuchar, still preserved, forms a curious example of Raeburn's earliest style. At the age of twenty-two he married one of his sitters, Ann Edgar, widow of Count Leslie, a lady of means; and, after practising his art for a time in Edinburgh, he resolved to study in Italy. In passing through London he visited Reynolds, who received him kindly, recognising his talent, and furnished him with introductions to Pompeo Battoni and other leading painters in Rome. After remaining two years in Italy he returned and settled in Edinburgh in 1787, the date of his fine portrait of the second Lord President Dundas. He soon received full employment as a portrait-painter, and before long attained acknowledged pre-eminence among the artists working in Scotland. In 1812 he was elected president of the Society of Artists in Edinburgh; in 1814 Associate of the Royal Academy, London; and in the following year full Academician. He was knighted by George IV. during that monarch's visit to Scotland in 1822, and was appointed king's limner for Scotland a few days before his death in Edinburgh on the 8th of July 1823.

Raeburn's style was, to some extent, founded upon that of Reynolds. Like Sir Joshua, he aimed at

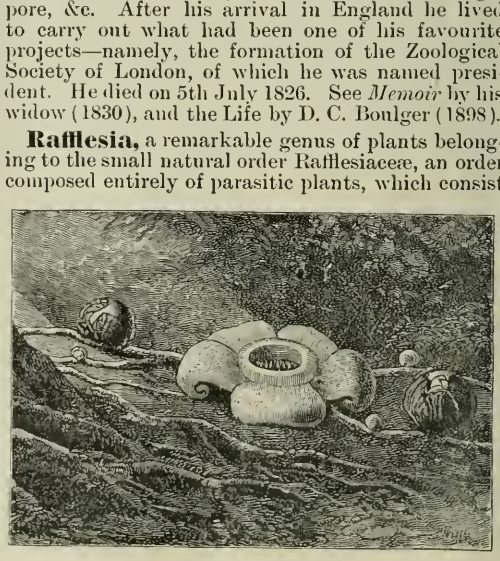
breadth of effect, a result attained by massing together the lights, and keeping them as far as possible distinct from the shadows, and so making each respectively effective: but he attained his aim in a manner and with a feeling that was characteristic and original. He seldom attempted to produce texture and luminosity of effect by thick impasto and semi-transparent painting, but adopted the opposite mode of painting, in a low tone, with a crisp, definite touch, working his colours with little admixture of any unctuous medium. In its decision and power of handling his style has been justly compared to that of Velasquez. In his portraits of men, in particular, the heads are most vigorously modelled, and the characteristic expression is seized in a singularly simple, direct, and effective manner; but works like the seated portrait of his wife and the portraits of the two Misses Grant Suttie sufficiently prove that he could portray the grace and dignity of comely womanhood. His reputation, always high in his native country, is becoming more widely spread, and his works are now much sought after. Among his sitters, who included almost all the celebrated Scotsmen of his day, were Sir Walter Scott, Lord Melville, Sir David Baird, Henry Mackenzie, Neil Gow, Harry Erskine, Dugald Stewart, Principal Robertson, Lord Jeffrey, and Lord Cockburn. Technically one of his finest and most complete productions is the bust portrait of James Wardrop. Exhibitions of his collected works were held in Edinburgh in 1824 and 1876; and an excellent series of his portraits was included in the Old Masters Exhibition of the Royal Academy in 1877. His art is fully represented in the National Gallery of Scotland, and examples of his brush are preserved in the National Gallery, London, and in the Louvre. Numerous engravings have been executed from his portraits.

See Life by his great-grandson, W. R. Andrew (Lond. 1886); *Portraits by Sir Henry Raeburn* (photographs, edited by Dr John Brown; Elliot, Edin.); *Sir Henry Raeburn, a Selection from his Portraits* (photogravures, edited by W. E. Henley; Edin. 1890).

Raff, Joachim, musical composer, was born at Lachen on Lake Zurich on 27th May 1822. He began life as a schoolmaster, but, encouraged by Mendelssohn, he devoted himself to music. From 1850 to 1856 he lived near Liszt in Weimar, then taught music at Wiesbaden until 1877; and from that year until his death, on 24th June 1882, he was director of the musical conservatory at Frankfort-on-Main. From the time he turned to music down to the end of his life Raff poured forth an incessant stream of musical productions, more than 200 in all. His works include many classes of composition, as symphonies, overtures, concertos for violin, 'cello, and piano, operas, quartetts, a great variety of pieces for piano and violin, and for piano alone. The symphonies *Lenore* and *Im Wald* are reputed his best works. He wrote with considerable poetic charm, much fluency, and great technical mastery, but undoubtedly wrote too much: he is often diffuse, and over-elaborates insignificant themes. In *Die Wagnerfrage* (1852) and numerous papers contributed to the *Neue Zeitschrift für Musik* he advocated the works and aims of the new German musical school.

Raffles, Sir Thomas Stamford, British administrator, was born, a sea-captain's son, off Port Morant in Jamaica, on 5th July 1781. In 1795 he was appointed to a clerkship in the East India House, and in 1805 assistant-secretary to a new establishment at Penang; eventually he was made principal secretary. In 1808 he made a voyage to Malacca, respecting which place, and the East Indies in general, he collected much valuable information. In 1811 Raffles accompanied the expedition against Java (q.v.) as secretary to the governor-general, Lord Minto, who himself took the chief command. The island was captured, and Raffles appointed lieutenant-governor of it and its dependencies. Much had to be done in the way of conciliating the native princes and chiefs to the British rule. He appointed British residents at the native courts, and framed rules and regulations for their conduct. He ordered a general survey to be made of the whole island, and checked the attempt of the native sultan of Jokjokarta to expel the Europeans from Java. His efforts were, however, chiefly directed to effecting a complete reform in the internal administration. By frequent personal interviews with the natives he sought to become acquainted with their manners and character, and to educate them and civilise them; and by them he was regarded with great esteem and affection. But at length his health gave way, and in 1816 he returned to England, stopping by the way at St Helena, where he had an interview with Napoleon. On his arrival in England he wrote his *History of Java* (2 vols. 1817), and received the honour of knighthood. Java having by this time been restored to the Dutch, Sir Stamford Raffles was appointed lieutenant-governor of Bencoolen, a settlement upon the coast of Sumatra, where he landed in March 1818. Shortly afterwards, to paralyse or combat the commercial prosperity of the Dutch in the eastern seas, and to repress the piratical propensities of the Malays, he was sent to form a new settlement at Singapore. In 1824 he was again compelled by ill-health to return to England. But the vessel in which he set sail took fire 50 miles out from Sumatra, and the crew and passengers escaped with difficulty in the boats. By this accident Sir Stamford Raffles lost the greatest part of his effects, including a fine collection of natural history, materials for various East Indian grammars and dictionaries, and for a history of Borneo, Celebes, Singapore, &c. After his arrival in England he lived to carry out what had been one of his favourite projects—namely, the formation of the Zoological Society of London, of which he was named president. He died on 5th July 1826. See *Memoir* by his widow (1830), and the Life by D. C. Boulger (1898).

Rafflesia, a remarkable genus of plants belonging to the small natural order Rafflesiaceæ, an order composed entirely of parasitic plants, which consist



Rafflesia patma.

merely of a flower, and form part of the Rhizantheæ (q.v.) of Lindley. The Rafflesiaceæ are natives partly of the Indian islands and partly of South America. The plants of the genus Rafflesia have neither stalk nor leaves, but are enormous flowers seated upon the roots of species of Cissus, making their appearance at first as a hemispherical swelling

of the bark of the root, and, after the bark has broken, rising up in the form of a head of cabbage, whilst the perianth is covered with imbricated bracteæ, which are more or less recurved after it has opened. The perianth is thick, fleshy, and 5-partite. The ovule is inferior, and contains many ovules; and the anthers, which are numerous, are seated under the revolute margin of the top of the style column. After the flower has expanded it diffuses a carrion-like smell, that even attracts flies, and induces them to deposit their eggs. The largest and first-discovered species, *R. arnoldi*, was discovered in 1818 in Sumatra by Dr Arnold, and was sent to the eminent botanist, Robert Brown, by Sir Thomas Stamford Raffles (q.v.). Its flower measures fully 3 feet in diameter, is capable of containing almost 2 gallons of fluid, sometimes weighs 10 pounds, and is the largest of all known flowers. A smaller species, *R. patma*, whose flowers are 16 inches to 2 feet in diameter, is highly prized by the Javanese as a medicine, for its strong styptic powers. *R. horsfieldii*, another Javanese species, is still smaller, its flowers being only 3 inches broad.

Rafn, Karl Christian, critic and archæologist, was born at Brahesborg in Fünen, 16th January 1796, and educated at the university of Copenhagen, of which he was appointed sub-librarian in 1821. It is to Rafn's unwearied exertions that Denmark owes the foundation (1825) of the 'Society for Northern Antiquities.' As secretary of this society he edited and published a great many ancient Scandinavian MSS., occupying about seventy volumes. He was named professor in 1826, and died at Copenhagen 20th October 1864. Among his numerous important works we may mention a Danish translation of Norse Mythic and Romantic Sagas (1821–26), and his *Antiquitates Americanæ* (1837), in which he shows that America was discovered by Norsemen in the 10th century (see Vinland).

Ragatz, a spa of Switzerland, in the south-east corner of the canton of St Gall, by rail 68 miles SE. of Zurich and 13 N. by W. of Chur (Coire); it stands at the mouth of the ravine leading to Pfäffers (q.v.), from which town it gets its healing waters by means of a pipe (1838–40) 2½ miles long. Schelling, the German philosopher, is buried in the parish churchyard. Pop. 1996.

Ragged Schools. The Ragged School, as distinct from the Certified Industrial School, is a voluntary agency providing education for destitute children, and so preventing them from falling into vagrancy and crime. Vagrant children, and those guilty of slight offences, are provided for in the Certified Industrial School; but the two institutions are frequently combined. The movement which established ragged schools was almost simultaneous with that which instituted reformatories. John Pounds, a poor shoemaker at Portsmouth, has the honour of originating the idea. For twenty years, up to the time of his death in 1839, he gathered the ragged children of the district round him as he sat at work. They came freely, and were taught gratuitously. The success attending his humble efforts soon led many more influential friends of the 'outcasts' to engage in the same work. In 1838 London had a Ragged Sunday School, which eventually became a free day-school. Field Lane followed in 1843. But the first ragged feeding-school was opened in 1841 by Sheriff Watson, in Aberdeen. In 1845 the Rev. Dr Robertson, not then aware of the existence of Sheriff Watson's, opened a similar school in the Vennel, Edinburgh. Soon afterwards Dr Guthrie's famous *Plea for Ragged Schools* appeared, a work which gave an irresistible impetus to the movement, and caused the author to be generally regarded as the father of ragged schools. A ragged school was founded at the Castle Hill in 1847 (since 1887 at Liberton). After this ragged schools spread over all the land, until there was scarcely a town of any importance that had not one or more. The Education Acts—England, 1870, and Scotland, 1872—introduced the principle of compulsory attendance at school; under this provision, a large number—especially in England—of such as were merely free day-schools became public schools. But, as the Education Acts make no provision for feeding the children, the managers of feeding-schools find themselves compelled to continue their efforts. In places where the system has been efficiently conducted juvenile crime has sensibly diminished. The ragged schools do not receive government aid. The capitation grant of £2, 10s., allowed by a Privy-council minute in 1856, was withdrawn in 1859.

Raghuvansa, a great Sanskrit epic, attributed to Kálidása (q.v.). The subject is similar to that of the Rámáyana, but begins with an account of Ráma's ancestors, 'the family of Raghu,' an ancient king of Ayodhya (Oudh). The text, with a Latin translation, was published by Stenzler (Lond. 1832).

Raglan, Lord. Fitzroy James Henry Somerset, eighth son of the fifth Duke of Beaufort, was born September 30, 1788. He entered the army in his sixteenth year, and in 1807 served on the staff of the Duke of Wellington in the expedition to Copenhagen. He went to the Peninsula as aide-de-camp to the duke, and in 1812 became his military secretary. As Lord Fitzroy Somerset his name became a household word. He was present at all the great actions of the Peninsular campaign, being among the first to mount the breach at the storming of Badajoz; and it was to him that the governor gave up his sword. On the return of Napoleon from Elba he served under the duke in Flanders, and lost his sword-arm in the crowning victory of Waterloo; and the very next day he was seen practising writing with his left hand. For his brilliant military services he was made K.C.B., and received orders from several foreign potentates. He was minister-plenipotentiary at Paris in 1815, and secretary to the French embassy from 1816 to 1819. The duke was appointed in 1819 Master of the Ordnance, and Raglan again became his secretary; and in 1827, when the former became commander-in-chief of the British army, Raglan was called to the Horse Guards as his military secretary. This office he held until the death of his chief in September 1852. He was then made Master-general of the Ordnance, and in October was called to the House of Peers as Baron Raglan of Raglan, in the county of Monmouth (q.v.). He had previously sat in the Lower House during the parliaments of 1818 and 1826 for the borough of Truro. While Master-general of the Ordnance he was sent as Commander-in-chief of the English forces to the Crimea in 1854 (see Crimean War). The desperate infantry battle of Inkermann obtained for Raglan the baton of field-marshal; but as the campaign proceeded unfavourable comments began to be made upon his conduct of the war. During the winter of 1854–55 his soldiers suffered unspeakable privations, and hundreds perished in camp and on board transports for want of the food, clothing, and medicines which were in store, but could not be found in the confusion and mismanagement that prevailed—the fault mainly of the home authorities. The siege continued without much apparent success until June 18, when a general assault was ordered, and when Raglan's troops, as well as the French, received a terrible repulse. Raglan had been suffering from a slight attack of

cholera, and the disaster of June 18 weighing upon his mind, he suddenly became worse, and died of exhaustion, June 28, 1855. His remains were brought to England and buried in the family cemetery at Badminton. He proved himself to be a skilful tactician, although it may be doubted whether he had the qualities of a great general. His personal bravery won universal admiration; and his courteous and noble bearing, his gentleness of temper and firmness of mind, and his constant worship of 'duty,' invest his character with something of the chivalrous. See Kinglake, *Invasion of the Crimea* (1863–87); and Hamley, *The War in the Crimea* (1891).

Ragman Roll (*ragman*, a word of uncertain origin, used in ancient diplomatic language for an indenture or legal deed), the name given to the collection of instruments which record the acts of fealty and homage performed by the Scottish nobility and gentry to Edward I. of England during his military progress through Scotland in 1296, and afterwards at the parliament held at Berwick. The original instruments of homage under the seals of the parties were deposited in the Royal Treasury of England, and have almost entirely perished; but the roll in existence in the Tower preserves a record of them. Its contents were given in an abridged form in Prynne's *Records*, and afterwards printed *in extenso* by the Bannatyne Club in 1834. An especial value attaches to the Ragman Roll as containing the largest and most authentic enumeration extant of the nobility, barons, landholders, and burgesses, as well as of the clergy of Scotland, prior to the 14th century, and the only genuine statistical notices of Scotland of the period.

Ragnarök (Ger. *Götterdämmerung*), the end of the world, when the gods (Odin, Thor, &c.) shall be overcome by their enemies and the world be burned up. See Scandinavian Mythology.

Rags. Fragments of almost all kinds of textile materials have now a commercial value. In the middle of the 19th century all white papers were made of rags, but the great increase in the consumption of printing-papers for daily newspapers and cheap periodicals has for many years necessitated the use of other materials, such as esparto, wood-fibre, &c. (see Paper). Linen and cotton rags alone are still, however, used for bank-note and other fine and strong papers, and are mixed with other materials, such as wood-pulp, for inferior kinds. These rags furnish the manufacturer with a material already half made into paper, so to speak, because the preliminary processes of boiling out the silica, &c. from straw or esparto are not required in the case of woven linen or cotton. Hence rags of vegetable fibre will always be valuable for paper-making.

Woollen rags have a higher value than linen or cotton kinds, or at least than mixtures of these. Old woollen clothes or shreds of such are called, in the manufacturing districts where they are worked up, 'Old Mungo' (see Shoddy). These rags are torn up, or 'ground up,' as it is termed, and re-manufactured into coarse flannels, druggets, comforters, &c. Some are actually ground into a sort of powder for flock wall-papers. The imports of linen and cotton rags into Great Britain in 1863 (before esparto was much in use for paper-making) amounted to 25,287 tons, valued at £502,681. In the same year 14,417 tons of woollen rags, valued at £551,824, were imported. In 1889 the imports were, of cotton and linen rags, 42,443 tons, valued at £426,322, and of woollen rags, 31,335 tons, valued at £669,438 (217,000 tons of esparto fibre were imported in the same year). A comparison of these figures will show the increased quantities now imported, as well as the depreciation in the value of rags. A large quantity, probably amounting to from one-third to one-half of the amount of British imports of linen and cotton rags, is re-exported to the United States; or at least rags to this extent are shipped from England thither, but a certain proportion of them may be of British production.

Rag-stone, an impure limestone, consisting chiefly of lime and silica, much used in Kent. It breaks up into pieces about the size of a brick, and is hard and flat bedded. The name is also applied to the hard irregular rock which frequently overlies better building materials. Besides being used for building purposes, hones or sharpening stones for scythes, &c. are made of it.

Ragusa (Slav. *Dubrovnik*), a decayed city of Dalmatia, stands on the east shore of the Adriatic, 100 miles SE. of Spalato and opposite the Gulf of Manfredonia in Italy. It is surrounded with strong walls, and has a very picturesque appearance when seen from the sea. The city seems to have been colonised by refugees from Epidaurus (now Old Ragusa, a few miles to the south-east), Salona, and other Græco-Roman towns destroyed by the Slav invaders of the Balkan peninsula. For some centuries Ragusa was a Roman outpost on the edge of the Slav states, and flourished greatly under the suzerain protection of Byzantium. Towards the end of the 12th century Ragusa was made to acknowledge the supremacy of Venice, though she retained a large share of autonomy. In 1358 Venice ceded her Dalmatian possessions to Hungary, and from that time down to the era of the Napoleonic wars Ragusa was generally accustomed to look to Hungary (i.e. the German empire) for help against her enemies, although from the beginning of the 15th century she was a free and independent republic. It was at the same time that she began to take a prominent place amongst the trading states of the Mediterranean, her prosperity being due to her position between the Christian powers and the empire of the Turks, and the privileges she enjoyed of trading freely with the subjects of the sultan. Her 'argosies' (i.e. 'vessels of Ragusa') traded as far as the Baltic; and a contingent joined the great Armada when it set sail for the invasion of England. Ragusa was the home from the middle of the 15th century of a remarkable literary movement, stimulated by the Renaissance (see Servia). During the course of the Napoleonic wars the French entered the city in 1805; this led the Russians to bombard the place. But in 1808 Napoleon declared the republic of Ragusa to be at an end, and in the following year incorporated it in the kingdom of Illyria. Since 1814, like the rest of the Dalmatian seaboard, it has belonged to Austria. Ragusa had, however, long before this declined from her former greatness. Though spared the attacks of foreign foes, she suffered repeatedly from fires, plagues, and earthquakes. The earthquake of 1667 was particularly disastrous. Yet Ragusa still contains several striking and interesting buildings, chief amongst them the palace of the rectors (chief-magistrates), built in the Gothic and Classic Renaissance styles between 1435 and 1464; the custom-house and mint, dating from before 1312 and finished in 1520; the Dominican church (1306) and monastery (1348), the former containing a picture by Titian; the Franciscan church and monastery (1317); the church of St Biagio (Blaise), the patron saint of the town, built in 1348–52, but rebuilt in 1715; and the churches of San Salvatore and Alle Dancé. The old cathedral, which tradition says was founded by Richard I. of

England when on his way home from Palestine, was destroyed by the earthquake of 1667; its modern successor (1671–1713) possesses some valuable silver ornaments and curiosities. There is also a large Jesuits' church (1699–1725). The harbour is small and now sanded up. Merchandise is landed and embarked at the harbour of Gravosa, a short distance to the north. Pop. 7245.

See T. G. Jackson, *Dalmatia* (vol. ii. 1887), and Pypin and Spasovitch, *Geschichte der slavischen Litteraturen* (vol. i. Leip. 1880), where the best books are quoted.

Ragusa, an old town in the south of Sicily, 31 miles WSW. of Syracuse, stands on the right bank of the Ragusa, 14 miles from the sea. In the cliffs below the walls and around the town ancient tombs have been excavated. A neighbouring grotto yields stones impregnated with petroleum. Ragusa is supposed to occupy the site of the ancient *Hybla Herœa*. It consists of two communes—an upper, with 24,183 inhabitants, and a lower, with 6260.

Ragwort, the common English name of those species of Senecio (q.v.) in which the heads of flowers have a spreading ray, the involucre has small scales at the base, and the leaves are pinnatifid. The British species are large coarse weeds, with erect stem, and yellow flowers; one species, the Common Ragwort (*S. Jacobœa*), a perennial, is too plentiful in many pastures. It is refused or disliked by horses, oxen, and sheep. It generally disappears from thoroughly drained land, at least after a little labour has been expended in grubbing up its roots. The fresh herbage has been used to dye wool green, but the colour is not permanent.

Common Ragwort (*Senecio Jacobœa*).

Rahel, the wife of Varnhagen (q.v.) von Ense, a woman of great intellectual abilities and wide intellectual sympathies, might almost be called the foster-mother of German genius. Her name was Rahel Antonie Frederieke Levin; she was a Jewess by birth, a sister of the poet Ludwig Levin (afterwards Robert-Tarnow), and she was born in Berlin on 19th May 1771. The first half of her life was spent in various towns of Germany, in Paris, and in Prague. Her first love having been killed in battle against Napoleon's army, Rahel became a Christian and married (in 1814) Varnhagen von Ense. Her house in Berlin was a gathering-place for men of genius—philosophers, poets, artists, and writers. She herself was greatly influenced when a girl by the writings of W. von Humboldt and F. Schlegel, and especially by Goethe, whom she called her *god;* and she in her turn recognised and encouraged the genius of Jean Paul, Tieck, De la Motte Fouqué, F. von Gentz, Fichte, Hegel, Gans, Heine, Thiers, Benjamin Constant, and others, but especially the writers of the Romantic school. Into the patriotic struggle against Napoleon she threw herself heart and soul. She died in Berlin on 7th March 1833. Her husband published a collection of her writings and letters as *Rahel* (1833), and three years later another collection. See also her correspondence with Veit (1861) and with Varnhagen (1875); and books on her by Schmidt-Weissenfels (1857), Assing (1877), and Mrs Jennings (1876).

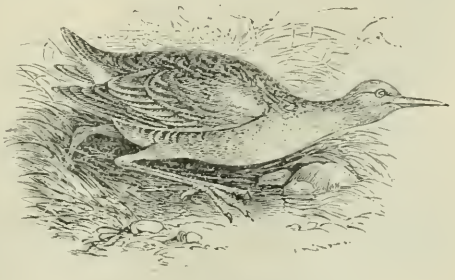
Rahway, a manufacturing city of New Jersey, on the Rahway River, 4 miles from its mouth, and 20 miles W. of New York. Pop. (1890) 7095.

Rai Bareli, or Rai Bareilly, a town of Oudh, India, stands 48 miles SE. of Lucknow, and has a large brick fort (15th century), a magnificent palace and tomb of a former ruler, and some fine mosques. Pop. 11,781.

Raiffeisen, Friedrich Wilhelm (1818–88), born at Hamm, near Coblenz, held various posts in the Prussian government service, but is known as the founder of the agricultural banks on a principle similar to the people's banks of Schulze-Delitzsch (q.v.) now found all over Germany, Austria, Switzerland, and Italy. He wrote several books in exposition of the system. See Co-operation.

Raikes, Robert, originator of Sunday-schools, was born at Gloucester, September 14, 1735. His father was printer and proprietor of the *Gloucester Journal*, and he succeeded to the business, keeping it till 1802. He loved children all his days, and his pity for the misery and ignorance of many in his native city led him about 1780 to start a school where they might be taught to read and to repeat the Catechism. Accounts of the scheme in the columns of his journal attracted attention, the movement grew, and Raikes himself lived to see his schools widely spread over England. He died 5th April 1811, and was buried in the church of L'Mary de Crypt, Gloucester, all the children that attended his funeral being given by his directions a shilling and a plum-cake. See Lives by Gregory (1877), Eastman (1880), and Harris (1899).

Rail (*Rallus*), a genus of birds of the family Rallidæ, having a slender bill rather longer than the head, wings of moderate length, long, powerful legs, and very long, completely-divided toes. The only European species is the Common or Water Rail, or Bilcock (*R. aquaticus*), found in marshy districts throughout England and in many parts of Scotland and Ireland. Many of the birds migrate southwards on the approach of winter. Like most of its relatives, the water-rail is very shy in its habits, and though it does not readily fly, generally escapes detection by threading its way swiftly and quietly through the reeds when its nest is approached. During the breeding season, however, it frequently utters a loud, harsh, groaning cry.



Water-rail (*Rallus aquaticus*).

The nest of the rail is made of coarse grass or reeds, usually well hidden among thick aquatic plants. The eggs, numbering seven to eleven, are 'pale creamy-white, sparsely flecked with reddish brown and ash-gray.' Two broods are reared in a season. The food consists of worms, snails, and soft vegetable substances. The adult bird is about

a foot in length; the prevailing colours of the plumage are olive-brown on the upper, ash-gray on the under parts. The tints of the female are duller than those of the male, while the young bird has the under parts creamy-white, barred with brown. Nearly allied to the water-rail are the Moor-hen and the Corn-crake (q.v.). Typical of the American rails is the Virginian Rail (*R. virginianus*).

Railways. The addition to tractive power through the diminution of friction to be obtained by the use of rails upon a roadway is so obvious a fact in mechanics that it is not surprising to find records from very early times of the employment of various materials with this object (see TRAMWAYS). Stone or wood was first used, but towards the end of the 18th century the improvements in the production of iron permitted the substitution of that metal on lines laid down in collieries and quarries. The employment of steam-power for locomotion on ordinary roadways was the subject of numerous experiments in various countries during the 18th century, but the credit of producing the first practical working engine is ascribed to Nicolas Joseph Cugnot (1725–1804), a native of Void in Lorraine. His carriage, constructed in 1769 at the French National Arsenal at the cost of the Comte de Saxe, ran on three wheels, and had two single-acting cylinders turning the front wheel. In the United States Oliver Evans (1755–1819) in 1804 constructed a steam dredging-machine which propelled itself on wheels to the river, a distance of 1½ mile. The improvements of the steam-engine effected by the inventions of James Watt soon led to better forms of locomotives, and comparatively successful models were produced by William Murdock; by William Symington of Dumbarton, the pioneer of steam navigation; and later by Richard Trevithick, whose steam-carriage was exhibited in London in 1803. The development of the high-pressure engine was largely due to Trevithick's numerous experiments and inventions. The first railway locomotive was tried, it is said, on the Merthyr tramroad in 1804, but the experiment was not successful, and to the venerable 'Puffing Billy,' patented in 1813 by William Hedley, and now to be seen in the museum of the Patent Office, must be ascribed the honour of being the progenitor of the enormous stud of iron horses now existing in all quarters of

Copyright 1891 in U.S. by J. B. Lippincott Company.

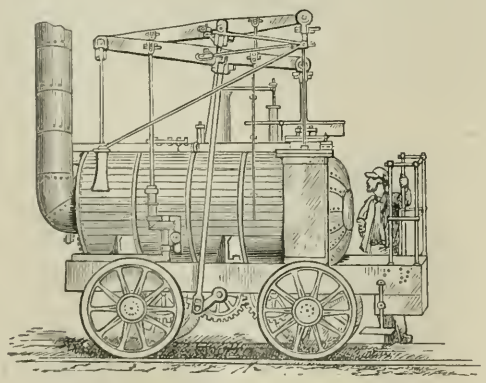


Fig. 1.—'Puffing Billy.'

the world. In previous experimental lines rack rails and toothed wheels had been provided under the mistaken notion that the adhesion of a smooth wheel to a smooth rail would not be sufficient. 'Puffing Billy,' after many trials and alterations, commenced regular working at the Wylam Colliery, near Newcastle-upon-Tyne, in 1813, and was kept in constant use until 1872, when it was purchased by the government.

A standing difficulty with the earlier forms of engine was the want of adequate and uniform steam-power, various devices being employed to secure the requisite draught to the furnace. The problem was first solved by George Stephenson. In 1815, after many previous experiments made while acting as colliery engineer, it occurred to him that the waste steam might be utilised as a blast to stimulate combustion, and from this idea, with the subsequent invention of the multitubular boiler (by Booth), securing enormously increased heating surface, the present form of locomotive was evolved. Other improvements made by Stephenson comprised the direct communication between the cylinders and the wheels, and joint adhesion of all the wheels by the use of horizontal connecting-rods. An engine constructed by him was the first to run on the Stockton and Darlington line, opened for public traffic on 27th September 1825. The engine weighed about 8 tons, and could make a speed of nearly 16 miles an hour. The Stockton and Darlington line was constructed for mineral traffic; and it was not until the opening of the Liverpool and Manchester Railway that the vast possibilities of the new form of transport were proved beyond cavil. The directors of that company, with a view to settle the method of traction on the line then approaching completion, offered a £500 prize for the best locomotive engine. Stephenson's 'Rocket,' comprising the improvements above mentioned, was the only one that complied with the conditions laid down, and at the competition which took place at Rainhill in October 1829 its superiority was at once manifest. It drew a coach with thirty passengers along the prescribed course at the rate

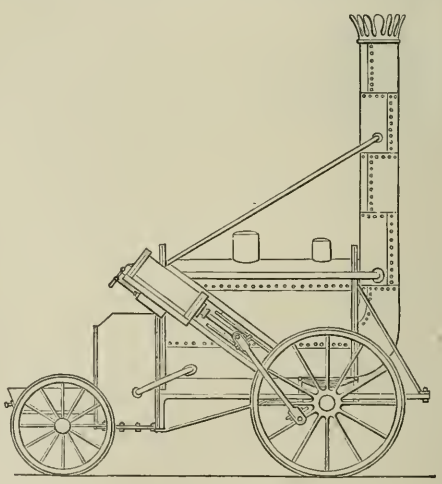

Fig. 2.—The 'Rocket.'

of 30 miles an hour. The 'Rocket' went into regular service on the opening of the railway in the following year. It weighed, with its supply of water, only 4½ tons, and long after it had been superseded by heavier engines, on one occasion ran 4 miles in 4½ minutes. All the many changes which have since been effected in the appearance and size of the locomotive have been more matters of detail than of principle. The 75-ton express passenger-engine, which runs at a speed of a mile per minute for miles together, does not differ materially in construction from George Stephenson's pioneer engines.

A modern development, however, of importance

for economy of fuel is the adaptation to the locomotive of the 'compounding' principle which has effected such a revolution in steam navigation. By this invention (see STEAM-ENGINE) the steam after doing duty in one cylinder or pair of cylinders is made available through its expansive power in another and larger cylinder. Engines formed on this plan are used extensively on the London and

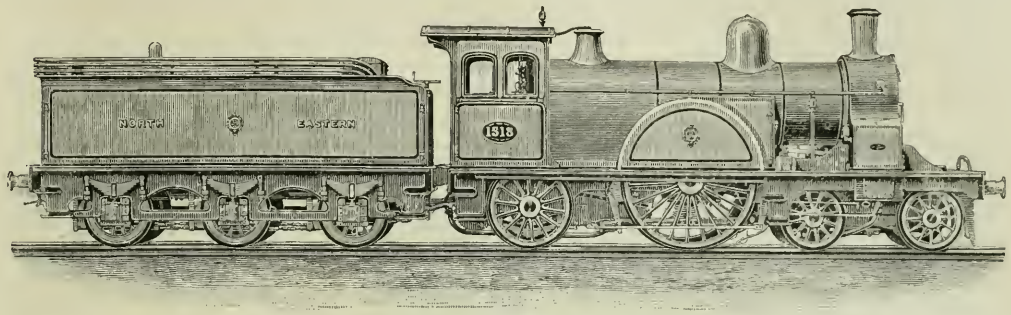

Fig. 3.—Compound Express Passenger-engine, North-Eastern Railway.

North-Western Railway, the North-Eastern, and the Great Eastern. A saving of from 10 to 15 per cent. in fuel is claimed by advocates of compound locomotives, the objection being a complication of parts.

Considerable diversity has hitherto existed in the type of locomotive on various lines; but the policy now adopted by nearly all the leading companies of manufacturing their own rolling-stock, and the obvious advantage of having interchangeable parts, has led of late to the gradual adoption of a more uniform style of construction for the different kinds of service required. As a general rule inside cylinders are in use on the through lines of the United Kingdom, it being contended by many authorities that for high speeds the placing of the weightier parts of the machine close to the centre of gravity minimises oscillation. It is held further that the moving part of the machinery is better protected by being placed within the wheels. On the other hand, the objections to be urged are the increased cost and

complication of the driving-axle and the comparative inaccessibility of the valves and pistons for purposes of repair. Outside cylinders have been adopted on the London and South-Western Railway and on other lines; and, supported by the bogie-truck, this form of engine approximates closely to the type in use on American railroads. The bogie-truck consists of a separate frame carried by two or more sets of wheels and attached to the engine or carriage by a central pivot; by this contrivance the wheels adapt themselves more readily to inequalities or to sharp curves. The boiler on English locomotives is invariably carried on a stiff plate frame, while in the comparatively cheaper form in use in the United States the running portion of the machinery is attached directly to the boiler by means of a bar frame, which in Britain is thought to throw undue strain upon the structure. Be that as it may, the types of passenger express engines in England and in the United States are undoubtedly approximating more and more closely (see fig. 4). The large single-driving wheel at one time generally used on express locomotives is now more rare, except in the case of some of the new compound engines, but for high speeds it possesses some advantages. For goods-engines the six coupled wheel, inside cylinder type,

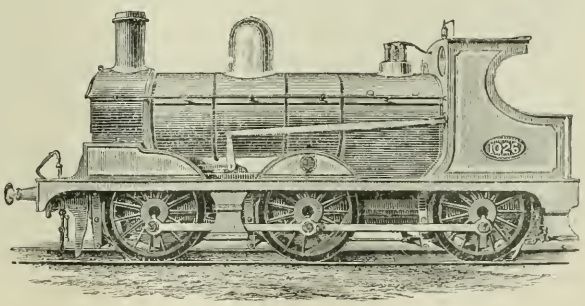

Fig. 5.—Six-coupled Goods-engine, L. & Y. Railway.

is in most general use, while the forms of tank-engines for local and suburban lines and for shunting purposes vary with the different companies and the different services to be performed. Of acces-

sories to working perhaps the most important added in recent years is the Injector (q.v.). A contrivance for picking up water in transit from troughs placed between the rails, the invention of Mr Ramsbottom of the London and North-Western Railway, is in use on some lines where long distances are run without stopping.

In the matter of fuel some very successful experiments have been made on the Great Eastern

Railway in the use of oil refuse in conjunction with coal, and liquid fuel is now employed on several of the company's locomotives and stationary engines (see FUEL). The use of liquid fuel by itself in locomotive work is open of course to some objections, such as the starting of the fires and the sudden reduction of temperature when the fuel is shut off, but these do not apply where the two

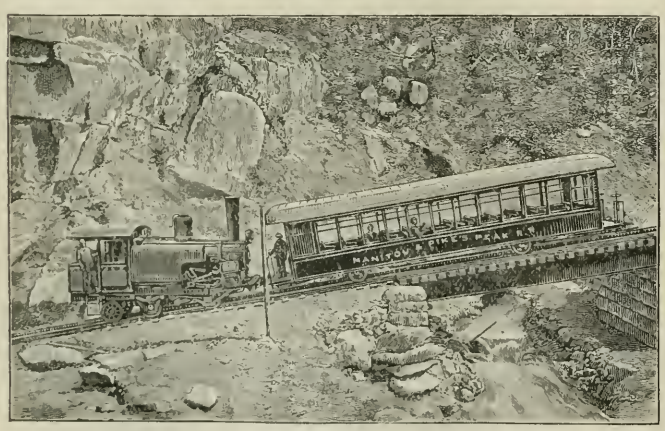

Fig. 7.—Train on the Manitou and Pike's Peak Railway.

fuels are interchangeable. The consumption and cost of coal alone per mile passenger express train may be taken at 34 lb. of fuel and 3½d. To do the same work 10½ lb. of liquid fuel and 15 lb. of coal are used, say 25½ lb., at a cost of 2⅘d. Of various contrivances designed to supersede or supplement ordinary forms of railway construction the most successful is the electric traction railway. The Central London Railway, opened in 1900 (the popular 'twopenny tube'), is the most important of an extensive series of London electric railways. See ELECTRIC RAILWAYS.

The overhead railways of New York are supported on iron columns, and traverse the principal streets, affording accommodation to an enormous number of passengers. Liverpool has also adopted an overhead railway for communication along the line of docks. The project for the carriage of ships and their cargoes by railway was brought to a practical test by the Chignecto Ship Railway (1889–92), across the narrow neck connecting Nova Scotia with the mainland. Lines have also been surveyed across the Central American isthmus. The rack system of railways, which was the earliest form of iron road, has been since adopted with advantage for the working of lines having steep grades. The Mont Cenis (1865) and Rigi Railway (1871) in Switzerland are among the best-known instances of this form of construction. The Zermatt Railway, 22 miles in length, opened in 1891, is the best example of the 'combined' working. The engine (metre gauge) has four cylinders, the outer pair of which are connected with wheels running on ordinary rails. The inner pair operate a central toothed wheel which runs on a single racked rail laid on such portions of the line as are of steep gradient. The two sets of cylinders can be worked separately or together as required. A similar line has been constructed ascending Pike's Peak in Colorado to a height of 14,134 feet. The highest points reached by the locomotive are Galera, a village in Peru, 15,635 feet, and those touched by a line from Galera rising 215 feet higher. The railway crossing the Andes in South America, from Buenos Ayres to Valparaiso, is to be worked on this system for some 17 miles, and on part of the state railways in Bosnia and Herzegovina it is employed.

The Lartigue system of light railways, of which several short lines have been constructed—one in Ireland and others in France—comprises only a single rail. The carriages or receptacles for goods are balanced on either side, pannier fashion, on a pyramidal structure of wood or iron, 3 or 4 feet in height, which carries the rail (fig. 8). A 'bicycle' railway has been proposed and an experimental line constructed in the United States, the engine and carriages being retained on the single rail by an overhead support held between small horizontal wheels. In the French 'gliding railway' (1888) a thin film of water is kept between the rails and the sledge which supports the carriage.

Carriages.—The builders of the earliest railways did not intend them for passenger so much as for goods traffic. On the Stockton and Darlington

line ordinary coaches placed on suitable wheels were used for the small passenger business which was encouraged, and until comparatively recent years the coach was the model for railway-carriage builders. Third-class passengers were accommodated in open wagons, with or without seats. So late as 1845 many of these vehicles had no windows, slight ventilation being provided by venetian blinds. On several of the lines no lamps were supplied in third-class carriages even for the night journeys. The first-class passengers booked their tickets as in coaching days, and their luggage was packed on the roof of the carriage to which they were allotted. As the passenger traffic increased the public became more exacting in their demands, and gradually more attention was given to the comfort of travellers, and the tendency of modern management is to add to the luxuriousness of the carriages, especially in long-distance trains. On account of the gradual decrease of second-class passengers, many of the principal companies abolished that class; but, owing to the companies who still retain it lowering the rates nearly to the level of third class, the numbers have considerably increased again in 1896–97. Composite carriages for first and third class in most express trains are fitted with lavatories and every comfort for both classes. Drawing-room, luncheon, and dining cars are also provided for day expresses; and sleeping-cars for night trains are fitted with all the luxury of a first-class hotel. There were in 1897 of locomotives in England 16,600, in Scotland 2092, in Ireland 787—total, 19,479; of carriages: England 51,294, Scotland 7163, Ireland 2954—total, 61,411; of wagons: England 493,428, Scotland 136,017, Ireland 18,030—total, 647,475.

The cost of the passenger express locomotive may be put at from £2500 to £3500; the more powerful engines, if made by locomotive builders, would cost from £4000 to £4500, but, like most of the carriages and wagons, they are usually built by the companies themselves. A goods-engine such as that illustrated would cost £1800 to £2200, and a tank-engine (without tender) £1500 to £2000. The cost of a Pullman carriage is from £2000 to £3500; of an ordinary first-class carriage, £550 to £700; second, £450 to £600; third, £350 to £450; of a coal wagon carrying eight tons, £60 to £70; a wagon carrying ten tons, £70 to £90.

Brakes.—The supply of brake-power has been the subject of many ingenious patents, and is dealt with in a separate article in this work. The use of continuous brakes of some approved form on all passenger-trains in the United Kingdom was made compulsory by the Railway Regulations Act of 1889. See the article BRAKES.

Railway Construction.—The cost of constructing railways is dependent on many conditions, such as cost of labour, the nature of the district traversed, and value of the land required. In England the last-named item has been a very serious one, and heavy parliamentary expenses have also added largely to the cost per mile, which, including equipment, averages £44,710 for the United Kingdom. The most expensive railway system in the world is the underground system known as the 'Inner Circle' line of London. A circular railway of this description was recommended by a parliamentary committee in 1864. The scheme has been carried out by two companies, the Metropolitan and the Metropolitan District, which have since extended their respective systems into the suburbs. This circle, including the purchase of land, which was the heaviest item, has cost from £600,000 to nearly £1,000,000 per mile. The Metropolitan line from Bishop's Road to Farringdon Street was opened on 10th January 1863, but the circle, owing to financial and other difficulties, was not completed until October 1884. Another very costly section of railway is that of the South-Eastern between Charing Cross and Cannon Street, London, which includes two large stations with hotels and two bridges over the Thames in its length of two miles. The cost of this short piece of line has been over £1,000,000

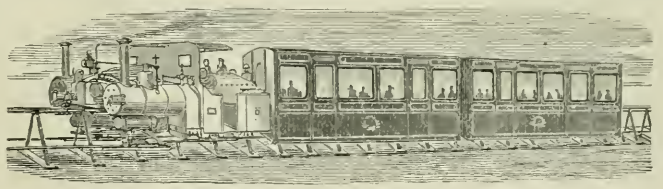

Fig. 8.—The Lartigue Railway.

per mile. In other countries the land acquired has been of much less value, and in many cases has been given by the government. Moreover, the traffic has not been so heavy, and consequently lighter works have sufficed than those which the Board of Trade require in Great Britain. The average cost of railways in the United States is thus under £12,000 per mile, and in Western Australia the railways have been built and equipped at about £4400 per mile. In flat tracts, such as the prairies, where the traffic is light, the rails can be laid with but little prepared roadway; but this is an exceptionally favourable condition, engineers in most cases having to span rivers (see BRIDGES), pierce hills or mountains (see TUNNELS), cut through elevations, and carry the line over low-lying ground on embankments. In an ordinary clay soil the cost of cutting and embankment may be taken at from 1s. to 1s. 3d. per yard, with about 2d. extra for trimming slopes, &c. In the case of chalk, hard rock, or sand the cost would naturally be much higher; and the length of cartage is also another important item. The roadway having been completed, a substantial bedding of gravel, burned clay, or other suitable material is laid, and in this are imbedded the 'sleepers,' to which the rails are fixed. A good navvy will dig and throw out into a barrow in a day of ten hours in common ground from 8 to 10 cubic yards, in stiff clay or firm gravel about 6 cubic yards, and in hard ground, where picking is required, from 3 to 5 cubic yards. The 'steam navvy' is now largely employed in railway work, and does in one day the work of from seventy to eighty men (see EXCAVATOR).
